

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

ASSOCIATION MEDICAL JOURNAL,

EDITED FOR THE

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION,

BY

JOHN ROSE CORMACK, M.D. EDIN.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, AND OF THE ROYAL MEDICAL AND CHIRURGICAL
SOCIETY OF LONDON; MEMBER OF THE ACADEMY OF SURGERY OF MADRID; ETC. ETC.

VOLUME FOR 1853.

LONDON: 1853.

PUBLISHED FOR THE ASSOCIATION BY THOMAS JOHN HONEYMAN, AT THE OFFICE
37, GREAT QUEEN STREET, LINCOLN'S INN FIELDS.

CONTRIBUTORS TO THE VOLUME FOR 1853.

- ADDISON, William, M.D., F.R.S., F.L.S., Maidstone
 ALFORD, Richard, Esq., Tewkesbury
 ALLEN, George, Esq., St. George's, Somersetshire
 ANCELL, Henry, Esq., Surgeon to the Westminster General Dispensary, London
 ANDERSON, W. J., Esq., London
 BARCLAY, A. Whyte, M.D., Medical Registrar to St. George's Hospital, London
 BARCLAY, John, M.D., Physician to the Infirmary, Leicester
 BAYES, William, M.D., Physician to the Dispensary, Brighton
 BEADLE, William V., M.D., Tewkesbury
 BEECROFT, Samuel, Esq., Hyde, Manchester
 BELL, Wm. Thos., Esq., Great Grimsby
 BENNETT, James Risdon, M.D., Physician to St. Thomas's Hospital, London
 BIRKETT, John, Esq., Surgeon to Guy's Hospital, London
 BLACK, Cornelius, M.D., Chesterfield
 BLOXAM, John Charlton, Esq., Newport, Isle of Wight
 BOWLING, J. P., Esq., H.E.I.C. Service, Bengal
 BROWN, Geo. Gwynne, Esq., Stourport
 BROWN, Frederick James, M.D., Chatham
 BROWN, Thos., Esq., Castle-Donnington, Leicestershire
 BROWN, Benjamin W., Esq., Wymeswold, Leicestershire
 BULLAR, Joseph, M.D., Physician to the South Hants Infirmary, Southampton
 CHADWICK, S. T., M.D., Bolton-le-Moors
 CHURCHILL, James M., Esq., Colchester
 COCKBURN, Archibald, M.D., Kensington, London
 COGSWELL, Charles, M.D., London
 COOPER, W. White, Esq., Ophthalmic Surgeon to St. Mary's Hospital, London
 CORMACK, John Rose, M.D., Putney, London
 COWDELL, Charles, M.D., Physician to the Hospital, Dorchester
 CRANG, James, Esq., Timsbury, near Bath
 CROWFOOT, W. E., Esq., Surgeon to the Dispensary, Beccles
 CULLEN, W. H., M.D., Surgeon to the Dispensary, Sidmouth
 DAYMAN, Henry, Esq., Millbrook, near Southampton
 DEANE, J., Esq., Chatteris, Cambridgeshire
 DUNCAN, P. Martin, M.B., Physician to the Essex and Colchester Hospital, Colchester
 DURRANT, Christopher Mercer, M.D., Physician to the East Suffolk Hospital, Ipswich
 DYSTER, F. D., M.D., Tenby, South Wales
 EDWARDS, Conway, Esq., Batheaston, near Bath
 ELSDALE, Robinson, Esq., Moulton, Lincolnshire
 FALLON, Edward Leslie, Esq., Everton, Liverpool
 FLINT, Richard, Esq., Senior Surgeon to the Infirmary, Stockport
 GALLWEY, M. Broke, Esq., Surgeon, Royal Artillery, Devonport
 GAMGEE, Joseph Sampson, Esq., Florence
 GRÄNGER, Richard D., Esq., Lecturer on Physiology and Structural Anatomy at St. Thomas's Hospital, London
 GRANTHAM, Thomas P. J., Esq., Burgh-le-Marsh, Spilsby
 GROVE, John, Esq., Wandsworth, London
 HAKE, Thomas Gordon, M.D., Physician to the Bury and Suffolk General Hospital, Bury St. Edmund's
 HALL, J. Charles, M.D., Lecturer on Anatomy, Physiology, and Pathology, Sheffield
 HARE, Samuel, Esq., London
 HARRISON, Isaac, Esq., Reading
 HAVILAND, Alfred, Esq., Bridgewater
 HERAPATH, W. Bird, M.D., Surgeon to St. Peter's Hospital, Bristol
 HIGGINBOTTOM, John, Esq., F.R.S., Nottingham
 HINGESTON, J. A., Esq., Brighton
 HINTON, Joseph, Esq., Blaina Iron Works, Monmouthshire
 HUNT, Thomas, Esq., Surgeon to the Western Dispensary for Diseases of the Skin, London
 IKIN, J. I., Esq., Leeds
 INMAN, Thomas, M.D., Lecturer on Materia Medica at the Royal Infirmary School of Medicine, Liverpool
 JACKSON, Edward, M.B., Ecclesfield, near Sheffield
 JEFFERY, John D., Esq., Worcester
 JENKS, G. S., M.D., Physician to the Sussex County Hospital, Brighton
 JENNINGS, Joseph C. S., Esq., Malmesbury
 JOHNSON, Henry, M.D., Senior Physician to the Salop Infirmary, Shrewsbury
 JONES, C. Handfield, M.D., Assistant-Physician to St. Mary's Hospital, London
 JONES, R. E., Esq., Long Melford, Suffolk
 KIDD, Charles, M.D., Kingsland, London
 KING, George, Esq., Surgeon Accoucheur to the Dorcas Society for the Relief of Lying-in Women, Bath
 KING, George, Esq., Melksham, Wilts
 LEE, Henry, Esq., Assistant-Surgeon to King's College Hospital, London
 LITTLE, T. S., Esq., Reading
 LLOYD, John, Esq., Llangefni
 LOWTHER, George, Esq., Hull
 LUND, G., M.D., Madeira
 LYON, Edmund, M.D., Consulting Physician to the Royal Infirmary, Manchester
 MACKENZIE, Fred. W., M.D., Physician to the Paddington Free Dispensary for Women and Children, London
 MACPHERSON, E. M., Esq., Port Louis, Mauritius
 MALLETT, G., Esq., Bolton-le-Moors
 MANN, Robert M., Esq., Surgeon to the Manchester and Salford Lying-in Hospital, Manchester
 MARKHAM, W. O., M.D., Assistant-Physician to St. Mary's Hospital, London
 MASON, Frederick, Esq., Bath
 MAY, George, Esq., Surgeon to the Royal Berkshire Hospital, Reading
 MILLER, James, Esq., Professor of Surgery in the University of Edinburgh, Edinburgh
 MILROY, Gavin, M.D., London
 MOFFAT, Thomas, M.D., Hawarden, Flintshire
 MORRIS, George S., Esq., Sydenham
 MOXHAY, William W., Esq., Royal Berkshire Hospital, Reading
 MURPHY, Edward William, M.D., Professor of Midwifery in University College, London
 NICHOLSON, Thomas, M.D., Antigua
 NOBLE, Daniel, M.D., Manchester
 OGDEN, James, M.D., Manchester
 OKE, W. S., M.D., Physician to the Royal South Hants Infirmary, Southampton
 PATERSON, Alex. Henry, Esq., Altrincham, Cheshire
 POWELL, R. H., M.D., London
 POYSER, Thomas, Esq., Wirksworth, Derbyshire
 PROBERT, Francis George, M.D., Physician to the Bury and Suffolk General Hospital, Bury St. Edmund's
 REEVES, Charles E., B.A., M.D., London
 RICHARDSON, Benjamin Ward, Esq., Mortlake
 ROBINSON, R. R., Esq., Camberwell, London
 RUDGE, Henry, M.D., Surgeon to the Dispensary, Leominster
 RUMP, Hugh R., Esq., Wells, near Fakenham
 SANDWITH, Humphry, M.D., Physician to the Infirmary, Hull
 SEMPLE, Robert Hunter, M.D., London
 SHEPPARD, Edgar, Esq., Enfield
 SIEVEKING, E. H., M.D., Assistant-Physician to St. Mary's Hospital, London
 SIMPSON, J. Y., M.D., Professor of Midwifery in the University of Edinburgh
 SMITH, William, Esq., Chesterfield
 SNOW, John, M.D., London
 SPEER, Stanhope T., M.D., Cheltenham
 STERLAND, W. J., Esq., Reading
 SWAYNE, J. G., M.D., Lecturer on Midwifery at the Medical School, Bristol
 THOMPSON, Theophilus, M.D., F.R.S., Physician to the Hospital for Consumption, London
 THOMPSON, Charles R., Esq., Oxted
 THOMSON, Spencer, M.D., Haunton, near Tamworth
 TRAVERS, Benjamin, Esq., Jun., London
 TUNSTALL, James, M.D., Senior Physician to the Eastern Dispensary, Bath
 TURNBULL, James, M.D., Physician to the Infirmary, Liverpool
 WADDINGTON, Edward, Esq., London
 WALSH, Walter H., M.D., Professor of Medicine in University College, and Physician to University College Hospital, London
 WALTON, Henry Haynes, Esq., Assistant-Surgeon to St. Mary's Hospital, London
 WATSON, Eben, M.D., Professor of the Institutes of Medicine in Anderson's University, Glasgow
 WEBB, Charles, Esq., Basingstoke, Hants
 WEST, Robert Uvedale, Esq., Alford, Lincolnshire
 WILLIAMS, Philip Henry, M.D., Physician to the Dispensary, Worcester
 WHITEMAN, R. H., Esq., Putney

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. I.

LONDON: FRIDAY EVENING, JANUARY 7, 1853.

NEW SERIES.

FELLOW ASSOCIATES,

A FEW words explanatory of our editorial plans will be naturally expected, and are most willingly tendered. Yet, in offering them, we must be allowed to say, that it is not by present promises that we wish our scheme of management to be judged. We well know, that actual performance can alone afford a correct view of the scope and spirit of a literary undertaking, and that even a well drawn and truthfully intended prospectus often misleads the most attentive reader. For this cause, therefore, we now beg formally to enter an appeal from the present to the future.

Twenty years ago, THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION held its first meeting at Worcester, at the invitation of its founder, Sir Charles Hastings, who then and there rallied around him some of the most eminent physicians and surgeons practising in the provinces. The foundations were broadly laid upon the principles of justice, honour, and fraternity; and time has shown that they were as securely as they were wisely planted. During the long period which has elapsed since our Association was established, the medical profession has undergone great and striking changes in its educational and social aspects: the apothecary of the olden time has gradually been displaced in almost every town and village by the well-informed practitioner: the highest accomplishments are no longer the monopoly of a few; and there is scarcely a place in the kingdom in which even the poorest cannot command the services of men more competent to grapple skilfully with the emergencies which occur in the practice of medicine, surgery, and midwifery, than the foremost physicians and surgeons of no very remote a period. Along with the improvement in skill, there has also been an evident advance in the tone of the profession. While we willingly admit that this wonderful reformation has chiefly resulted from the licensing boards having step by step enlarged the course of study required from candidates, and rendered more searching the examinations to which they were subjected, we are equally convinced that the proceedings of the Provincial Association have in no small degree contributed not only to accelerate the happy changes to which we have adverted, but by manifesting them to the public, to give to the profession a social status and a political weight which it never previously possessed. At this moment, unchartered though we be, our influence is as powerful in high places as that of any of the old medical Corporations; and it is well known that no measure of medical reform could pass through Parliament, which was opposed by the Provincial Medical and Surgical Association.

From the first, but especially in later years, the Association has exercised an invigorating and purifying influence within its own ranks, and has often extended these benefits to the profession at large. Members guilty of irregular practice and unprofessional conduct, when discovered, have been energetically proceeded against; and some offending

brethren have been admonished, while others have been expelled, or have been allowed to resign to save themselves from this extreme penalty. The anniversary general meetings and the district branch meetings have greatly strengthened feelings of harmony and good-will, by bringing into personal contact brethren who would otherwise have remained widely separated from each other by space and the engrossing duties of practice; and in this way the pleasant friendships of youth and early manhood have been perpetuated, while many new and endearing ties of amity have been formed and cemented. The publications of the Association have also greatly promoted a spirit of scientific inquiry, original research, and accurate clinical observation. These, and such like, have been the noble objects for which the Association has uniformly contended, and in behalf of which we trust it may ever unflinchingly and zealously exert its power.

But it is not only in the provinces of England—the original sphere of its operations—that the influence of the Association has been seen: its operations upon professional circles, and upon the public mind, have recently been as powerfully felt in the metropolis, and in Scotland, as in the English counties. One, indeed, of the most signal benefits which the Association is now conferring upon the profession is the extensive union which it is establishing among all the loyal sons of physic throughout the British empire, who are willing to enlist under the catholic colours of legitimate medicine. Our Association repudiates all party, sectarian, and selfish objects; and in proof, as well as in pledge, of the respect which is paid to this maxim, it is only necessary to mention that our list includes members from all parts of England and Scotland, practitioners of every class, and professors of almost every school.

To many, we fear, the statement of facts which we have now made may have appeared unnecessary and tedious; but we have deemed it better to run the risk of being blamed for commencing our labours with an address distinguished chiefly by its dryness and common-place, than to be accused of failing to record at the very outset what we believe to be the principles entrusted to our defence, and by acting in accordance with which we desire to seek your approbation. And here it may be well to state, that we interpret the motion adopted at Oxford, in July last, in favour of publishing the journal weekly in London, in place of fortnightly at Worcester, not as an expression of opinion in favour of radical changes, as was feared by some, who, for a time, doubted the soundness of that decision: but simply as a strong declaration of the necessity which the progress of events had imposed upon the Association, of pursuing the line of duty which had hitherto been acted upon, with that augmented vigour which a wider sphere of action required—a vigour which could only be effectively developed by greater frequency of publication, and by the possession of a literary and scientific centre in London, where editorial resources are more abundant, more varied, and more easily available, than in any other city in the world.

While, therefore, you are this day addressed from another

locality, and by another representative, there is no call to transfer your allegiance to another cause. On the contrary, you are invited to rally more closely than ever around the same worthy banners under which you have for the last twenty years, so consistently, so gallantly, and so victoriously contended. You are invited to assist us, while we endeavour to defend and to extend the good cause; so that, ere long, our Association may embrace within its pale every legal practitioner of medicine who is adequately impressed with the awful responsibility of his calling, and who desires to see a strong and impregnable wall of partition built up between the sons of legitimate physic and those marauding bands of impostors, whose only real medical creed is lucre, and who, under various sectarian denominations, recklessly traffic in the health and lives of a medically ignorant, and therefore easily deluded population.

As regards the character and arrangement of the materials which it will be our weekly duty to bring under the notice of our readers, we purpose to speak in future articles. This much, however, we must now premise, that we intend to adopt, as nearly as possible, the following programme, which was published by the Journal committee appointed at Oxford.

- I. LEADING ARTICLES.
- II. ORIGINAL COMMUNICATIONS.
- III. BIBLIOGRAPHICAL NOTICES.
- IV. PERISCOPIC REVIEW.
- V. REPORTS OF SOCIETIES.
- VI. ASSOCIATION INTELLIGENCE.
- VII. NEWS AND TOPICS OF THE DAY.
- VIII. OBITUARY.
- IX. APPOINTMENTS.
- X. EDITOR'S LETTER BOX.
- XI. ADVERTISEMENTS.

We confidently hope to be able to make the Journal what it ought to be—a luminous and practically available epitome of the medical science and literature of the age—such as men of learning and leisure may read with profit and pleasure, and which will supply, in a well-digested form, to our more toilsomely occupied majority, all that they have time to peruse, or can conveniently procure.

Under no pretext whatever, by name, allusion, or innuendo, shall we ever discuss, in our editorial articles, the alleged misconduct of any member of our body. The Association has laws and ethical tribunals before which such charges can be promptly brought, and impartially investigated. Until an associate be actually convicted of unprofessional conduct, it is assuredly the duty of the editor of this journal to take no part, for or against him, and also to save him from the publication of *ex parte* statements, which have often injured even the innocent. When the reports of cases involving ethical questions are officially transmitted to us by the general or local secretaries, they will be printed in that department of the Journal which is devoted to "Association Intelligence".

If disputes should at any time arise regarding the administration of the laws, or regarding points of order in the conduct of public business, we shall (editorially) withhold all expression of opinion. In such matters, it is clearly the duty of the Association or of its Executive Council, and not of the Editor, to adjudicate.

The ORIGINAL CONTRIBUTIONS published in each number will consist of a conscientious selection from those

which are sent to us. If contributors concentrate what they have to say, by avoiding surplussage of words, and needless prefatory compilations, they will find that their papers are especially welcome. Elementary lectures we do not intend to insert. Short and pithy papers on practice and pathology are what we chiefly require; for it is only by being well supplied with such articles, that we can give to the original department of the journal the necessary elements of practical value and interesting variety. Able and elaborate articles we will do our best to print when we can; but we must frankly state that we do not think that long papers can be published with any advantage, except in occasional volumes, or what would perhaps be better, in periodical parts of Transactions. If five or six hundred members were voluntarily to subscribe a few shillings annually, such quarterly or half-yearly parts as we refer to, might be punctually supplied to them. In this way, there would be no additional tax levied upon those who did not wish the Transactions; and what appears to us a matter of great importance, the weekly journal would be kept free from matter which, though of sterling value, might not always prove of general interest.

The BIBLIOGRAPHICAL NOTICES will be analytical, descriptive, or critical, according to the nature of the work. It is not intended to publish elaborate essays under the name of Reviews.

The PERISCOPIC REVIEW will necessarily vary in value, according to the abundance or scarcity of materials: but it will represent all languages and all departments of medical science. We cannot better explain what we wish it to be than by quoting the following passage, and saying that we intend to urge strongly upon those who are to co-operate with us in preparing the periscopic articles, that the nearer they approach to Dr. Gooch's standard, the nearer will they attain complete success.

In the preface to his "*Account of some of the most important diseases peculiar to Women*", he says:—"Do not attempt to dispense with reading, but dispatch it as speedily as is consistent with accuracy. Keep a note-book, read the most esteemed original writers upon the most important subjects of your art, and while reading them, note down briefly those points which you wish to remember, so as to have no occasion ever to look into the book again. Provided you get the points of the work, the more briefly you do it the better: if you are skilful at this, you will find that a page will hold a pamphlet, and twenty pages will hold a bulky volume: if you read German, read Richter's *Bibliothek Chirurgisch*, for he is the greatest master of the art of condensed analysis. Thus, your manuscript volume will become a bibliotheca of your branch of medicine, and you will never afterwards have occasion to consult the books themselves. There are some writers whom it would be wrong to abandon thus; master minds, whom we return to again and again, not merely for the knowledge which they contain, but to observe how their minds worked, and the older we grow the fonder we become of them: such, in England, are Harvey on Physiology, and Sydenham on medicine; but few such minds appear in any branch of knowledge; and with most of them, when you have squeezed out the juice, you may safely throw away the rind."

In conclusion, it remains for us to say, that we trust that our scheme of management may not be judged of by this imperfect sketch, but by the scope of the annual volume. If we have written somewhat dogmatically, we have not

done so from an over-weening confidence in ourselves, but from a deep conviction of the necessity of laying down, at the very outset of our labours, the principles upon which we intend firmly to act. Mistakes—and perhaps serious ones—we may sometimes unwittingly make; but the history of every literary undertaking will bear us out in the assertion, that the occasional errors of judgment committed by a conscientious and unfettered editor, are far less injurious than the undecided tone, and uncertain policy, which arise from divided responsibility, even when that responsibility is shared among the ablest and the best of men.

Our determination is to do our utmost, and on that plea we crave your co-operation, your sympathy, and your generous indulgence.

JOHN ROSE CORMACK.

THE BENEVOLENT FUND.

THE recent accession of new members has been so great, that it would be wrong to allow the first number of the New Series of the Journal to appear without some allusion to the BENEVOLENT FUND—that jewel in the crown of our Association.

The Benevolent Fund was originated in the year 1835—36, and was finally adopted and recognised by the Association at its annual general meeting; it being justly argued, that the Association, without a Benevolent Fund, would be as defective as must be the character of every individual, who, in the arrangement of his income, does not make provision for that charity which is the “bond of perfectness”.

Cradled in adversity, the Benevolent Fund struggled on in comparative obscurity through the first nine years of its existence; but, in the last six years, under new auspices and a new committee, it has flourished, and produced happier results.

Its simple object is, to afford *temporary* relief to distressed medical men, their widows, or orphans; to step in where no other society can be available; to give that aid which shall raise the sinking practitioner from crushing difficulties—shall rescue the widow from indigence—shall snatch the family from starving—shall foster those provident feelings which secure independence to the broken spirit, and afford time for the restoration of the fallen fortunes of the distressed, by means of their own industry, directed by their restored energy and integrity of character.

The relief of the Benevolent Fund is confined to the regularly-educated medical man, to cases of actual distress, and to those of irreproachable moral character. Besides these, no other passports to its aid are required; and in cases of actual emergency, the Treasurer has the power to advance a small sum for *immediate relief*, without waiting for a grant from the Committee.

The average income of the Benevolent Fund, arising from *subscriptions*, during the first two years of its operation, was £22:10; that of the last year was £655. In the first eight years, sixteen cases were relieved; in the last year, aid was given to sixty-five cases; besides which, annuities were granted to six parties, at a cost of £105 per annum. The annuities arise from the interest of the accumulated donations, which is therefore certain and unchangeable. The invested capital of the Fund now amounts to upwards of £3,000. Thus the Benevolent Fund is supported by *donations* which accumulate, and by *subscrip-*

tions which are expended in the relief of temporary distress; thus affording an opportunity to every individual to select the mode of charity best suited to his inclination and his purse. The number of subscribers during the first two years was twenty-three; in the last year it was nearly *fourteen hundred*.

These contributions are perfectly *voluntary*; but we cannot take leave of the subject without reminding our readers that the Fund is an *integral* part of the Association; that its income is insufficient to meet the demands upon its purse; that it has an inalienable claim upon every member of the Association; and that it behoves *each*, when he remits his subscription to the general fund, to give also to the benevolent fund according to his ability, and according to the “riches of his liberality”. Subscriptions are at all times thankfully received by its valuable and devoted Treasurer, Mr. NEWNHAM, of Farnham, Surrey.

MICROSCOPICAL DISCOVERY IN ITS BEARINGS ON PATHOLOGY AND PRACTICE.

In these days there is little need to enlarge upon the advantages to be derived by pathologists from the use of the microscope. In this, as in other branches of study, knowledge is indeed increasing, the chief risk being lest it should outrun wisdom, and lest we should come to esteem the acquisition of facts more highly than the use of them. As each new El Dorado is opened up, men rush to the diggings, often much overvaluing the nuggets which they disinter; and now that “histology” has become a household word, and that every one has a microscope, the reputation of the instrument is in no small danger of suffering from the blind worship of its devotees. The mode of using it is explained in thick octavos; to the microscopical anatomy of man extensive works are dedicated; and the toilworn practitioner shrinks from the gigantic study of the *infinitesimal petit*.

In our student days we once were honoured by an invitation to a metropolitan Microscopic Soirée; we went high in hopes of greatly adding to our store of useful knowledge,—when lo! the entertainment consisted chiefly of an elaborate exhibition of many lice from various brutes: our own hair stood up for an instant with instinctive repugnance, and for that evening we sickened at the microscope. Our mature judgment indeed will not rashly cast a slur on the study of the *Pediculi*, which no doubt has many points of interest; but we venture at least to suggest that there are other subjects in which medical men have a deeper interest; and thus it is, that while we consider it an essential part of the plan of this Journal to exhibit the advances of microscopical investigation in their bearing on pathology and practice, we deem it needful so to sift and winnow the ample reappings of our microscopical friends, as that no one of our readers shall have reason to think that time wasted which he may have spent in the perusal of our summaries.

Medical men, who prosecute earnestly one special path, be it in the laboratory or through the lens, are apt to give to the result of their investigations more than its due weight in a practical point of view, and to become one-sided and bad practitioners. All things continually studied tend to magnify themselves unduly,—and this the more, the smaller they naturally are: and thus cells and fibres come to loom so

large, as to shut out from view the great principles of pathology, and the old diagnostic land-marks of our practical forefathers. We trust that in the papers which this article introduces, we shall be able to avoid these errors; and to connect the new facts and the new means of diagnosis which the microscope is ever opening to us, with the old truths, and with the old characteristics of disease.

Our plan will be briefly this—*To give from time to time notices, as succinct and clear as may be, of the progress of microscopical discovery, chiefly in its bearings on pathology and practice.* We may analyze the novelties which a new work contains, or we may group together a series of scattered facts on some particular subject, and if need be, make the matter plainer by woodcut illustrations; but our main object throughout will always be to connect the new with the old, and both with those principles of pathology and points of practice which may be rendered weightier and more precise by the additions which we notice.

Some may feel that these sentences speak but a cold prologue to this department of the Journal; but we hope that our readers will ere long admit that our summaries of microscopical discoveries can speak well for themselves. We think that their chance of acceptance will not be less because that they present themselves modestly, and because we do not declare that along *this path alone* must he advance, who would carry forward the flag of medical science, by rendering the discrimination of disease more accurate, or its treatment more successful.

MEDICAL HISTORY A NEGLECTED BRANCH OF MEDICAL EDUCATION.

OF the various improvements in the prevailing systems of medical education which are required, in order to secure the healthy advancement of our profession, none greater could be mentioned than that of affording to our younger brethren some ready means of obtaining an adequate knowledge of THE HISTORY OF MEDICAL SCIENCE.

It is at once a remarkable and a painful fact, that nine-tenths of the profession are almost wholly uninformed on this important subject. A few great men in the History of Medicine may, it is true, now and then be mentioned, as Hippocrates, Galen, Harvey, and Haller, but then they are only noticed in connexion with universal history, precisely as Plato, Aristotle, Bacon, and Franklin, are noticed; and in this sense, the names of both groups of philosophers are equally familiar to general and to medical scholars. In like manner also, a few leading facts are known, with reference to the labours of the illustrious medical men of past ages; but here, in most cases, such knowledge ceases. Estimates, as to the influence which these men have exercised on worldly matters in general, and on medical matters in particular, are never made, and what is still worse, a few of the more familiar names in the past records of medicine, are allowed to stand forward, as embodying all that has been useful, and all that has been great.

It seems indeed, as a rule, to which of course there are many worthy exceptions, that medical men of this country and this time, act on the strength of the modified proverb, "sufficient for the day is the knowledge thereof"; and thus we behold, that whilst they gather into their

mental garner, with determined eagerness, new harvests of unwinnowed information, they sensitively shrink from every scrap of antiquity.

Is there not something radically wrong in this line of action? Is it right that the ancient archives of medicine should be left unsearched? Are there no great truths to be learned from such venerable records? Is there not, in the total neglect of studies which relate to the medical annals of past times, a danger that the present age of medicine shall become conceited, self-complacent, and shallow? And, lastly, is it not very unjust to forget the labours of our great medical fathers, merely because those fathers are dead, and "unavoidably prevented" from being present to defend their rights? We think the true answer to each of these questions will occur to every intelligent and truthful reader.

But many will ask, How is the study of medical history to be introduced into medical education? and will inquire if the curriculum of the medical student is not already overcrowded with studies universally admitted to be essential? We could settle these objections at once by one short sentence—*let the period of medical education be made longer*; but as this is of course quite a wild proposition, very unpalatable to students, and still more unpalatable to boards of examiners, who banquet on the half-cooked medical dishes under which the table of society groans, we drop it with becoming haste, and observe that there are two periods when the knowledge, for the value of which we now contend, might be obtained.

First.—The study of the history of medicine could well be taken up at the time when youth is preparing to enter on his strictly professional course of study; while thus learned it would form a most useful element in what is called the classical or preliminary examination of students, now becoming so common. Secondly.—It might most usefully be obtained after the student has passed through every dreaded ordeal, and while he yet waits in his study ready to run a tilt with disease or death, whenever the gentle public may deign to call him out to contend as their champion against such formidable foes.

But what results are to follow the study of medical history, inquires the "practical man"? We have not now the space wherein to enumerate all the results, but we may glance at some of them. The power of making great generalizations in matters pertaining to medical science, is one.—A knowledge of the influence of medicine on the world at large, is a second.—The justice which should be rendered to our laborious medical predecessors, is a third.—The important lessons of honour, integrity, industry, and in fact of every virtue, which would flow from the study of the characters of those predecessors, is a fourth;—and so we could fluently proceed through many columns.

We advocate the study of medical history, then, and we shall in future articles continue to do so, since we are deeply impressed with the immense benefits to our profession which must flow from its general cultivation. We are, perhaps, the first medical journalists who have thus specially directed attention to the subject, but we have no misgivings as to the soundness of our views, or fears as to final results. If the attention of the profession be kept judiciously directed to the matter, we doubt not, that ere a quarter of a century has elapsed, the value of the study of medical history will be duly appreciated, and that though an embryo now, it will be "a giant in those days".

THE STUDY OF EPIDEMIC DISEASES.

AT p. 22 will be found a very important letter from DR. GAVIN MILROY, in which he suggests a method by which the organization of the Association might be made subservient to the elucidation of the Natural History of Epidemic Diseases. We cordially concur in the views so well expressed by DR. MILROY; and we take the earliest opportunity of stating, that it will afford us much pleasure to register, classify, and publish in a convenient form, the epidemiological and meteorological information which may be transmitted to us. At present we have not space to enlarge upon this subject; but we propose to return to it in an early number, when we also hope to be able to submit the details of a plan by which the proposal of DR. MILROY may be effectively carried out.

ORIGINAL COMMUNICATIONS.

OPIUM IN IRRITABLE AND ANÆMIC STATES OF THE BRAIN IN FEVER.

By HUMPHRY SANDWICH, M.D., Physician to the Hull General Infirmary, and Lecturer on the Practice of Medicine in the Hull School of Medicine.

"THE employment of opiates in cerebral affections," says Dr. Holland,* "is a question of much interest and various difficulty"; and "there is great scope for further research on this subject, as on all that relates to disorders of the brain, and a strong presumption that opium is capable here of larger and more beneficial application than has yet been given to it". His subsequent remarks, in the same article "On the Use of Opiates"; embrace, but are not restricted to, its use in fever, and may be consulted with advantage. Meanwhile, the profession owe Dr. Latham a large debt of gratitude for his masterly sketch of those irritable and anæmic states of the brain in fever, which demand the cautious use of this powerful narcotic. His brief but comprehensive paper on the subject, published twenty years ago,† is still a beacon to guide us in a path, which his observant genius first irradiated.

The class of cases of purely irritable states of the brain is to be discriminated, as Dr. Latham shows, less by any series of symptoms flowing from the brain, than from the single symptom of a state of protracted wakefulness. Nor is the wakefulness pathognomonic *per se*, but to warrant the use of opium, it must occur in combination with an irritable state of the nervous system, induced either by depressing moral agencies, or by the physically exhausting one of alcohol. The fever may be mild, and "exhibit a sort of contrast with the existing affection of the brain"; or it may correspond in severity with the sensorial disturbance up to a certain point, and then the symptoms referable to the brain outrun the febrile phenomena. In the latter case, though vascular over-action may have been kept in check by general or local bleeding, still the sensorial disturbance progresses. "As other symptoms are relieved, the delirium is even aggravated." We are thus presented with two forms of irritable brain in fever,—the one being marked by simple wakefulness with no other cerebral symptom, and the other by wakefulness coupled with symptoms of high sensorial excitement. Both varieties are "incident only to those, whose habits and mode of living have been calculated to do an abiding injury to the nervous system, and who have been long actually suffering from such injury".

The same acute observer, however, recognizes another variety of sensorial disturbance in fever, which is obviously associated with anæmia. We shall quote his words:

"Again, I have seen the sensorial affections incident to fever, which require opium for their cure, manifest themselves in another form. There has been high vascular action from the first; and large depletion has been required to subdue it and to guard particular organs, and especially the brain, from injury. Under such treatment, all has gone on successfully, and the

patient has reached the point of convalescence, with a soft pulse, a cleaning tongue, no pain, and refreshing sleep for two or three days; when suddenly (the tongue, the pulse, and all other circumstances continuing the same) some strangeness of manner has arisen, and then the wildest delirium, and then the unrestrained passage of the evacuations. I have known the transition from such a state of *convalescence* to such a state of peril, take place in a few hours; and I have known the patient again brought back to a state of convalescence in twenty-four hours by a moderate dose of opium. This is a rare form of disease, but one in which, when it does occur, opium is eminently indicated."

Now here was an anæmic condition of the brain, but not to so frightful an extent as in the case to which I beg leave now to call the reader's attention; and I may add, that its very extent suggested, not "a moderate dose of opium", but the liberal use of the remedy.

CASE. Mrs. T., a rather delicate woman, about thirty years of age, fell into fever during the second week of November 1848, when near the close of the third month of pregnancy. Her abode was in the vicinity of open and offensive ditches; and it was soon evident that the attack would prove severe. The case ran on nearly three weeks, with symptoms of grave and increasing disturbance of the sensorium, and other indications of low typhoid fever. By careful management, indeed, had she not been pregnant, the disease might probably have evinced no symptoms of more than usual danger. On the 2nd day of December, the irritation of the great nervous centres palpably interfered with gestation, and abortion was the speedy consequence. The process unhappily was accompanied with a very profuse hemorrhage, which ceased indeed with the expulsion of the fœtus and placenta, but which in twelve hours had brought the patient into imminent peril. Along with continued sensorial disturbance, there were the signs of incipient collapse, as manifested by a rapid and fluttering pulse, unequally diffused animal heat, and laborious respiration. Moderate stimulation by wine had been latterly allowed; but it now became necessary both to give ammonia, and augment the dose of alcohol. The extreme restlessness, subsultus, and other alarming symptoms demanded, however, a cordial, on which more reliance could be placed than even on the stimulus of brandy. Life, in short, was now in extreme peril. Calling to mind the marvellous examples of the virtues of opium in uterine hemorrhage *without fever*, as recorded by Dr. Stewart in the *Medico-Chirurgical Transactions*,* as well as its power to sustain life in the fearful struggles of angina pectoris, and reasoning from the analogy of its virtues *in fever*, when the circulation is at the same time depressed by antimony, as also in delirium tremens, when excessive and habitual intoxication may be presumed to have exhausted the vital energies of the brain, I determined on an attempt to steady the heart, restore the capillary circulation, and calm the irritation of the nervous centres by a full dose of opium. Mr. Millin, the surgeon with whom I was attending in consultation, fully concurred with me in these views. We accordingly gave a draught containing a hundred drops of laudanum. The effect justified our most sanguine hopes. Sleep ensued, the circulation rallied; every symptom of cerebral irritation subsided, fever broke up, and convalescence was speedily established.

The present short practical paper contemplates chiefly that condition of the brain in fever, in which an anæmic state of its vessels warrants us in availing ourselves of the stimulant properties of opium, with a view to maintain the equilibrium of the cerebral circulation. In such cases the use of the drug is salutary, chiefly as it favours an amount of congestion essential to healthy sleep. Not that its effects on vascular structure are its only merits; for it is fair to argue with Dr. Holland, that as "narcotic substances have effects, locally applied, on nervous sensibility", so also "there can be little doubt, that in sleep it is the same singular influence, extended more widely over this part of organization, and reaching through the cerebral part of it, the higher faculties of our being".† But in anæmic conditions of the brain in fever, the use of opium seems to be salutary, we repeat, chiefly as it favours an amount of congestion essential to healthy sleep. "It is certain, that the states of sleep and coma frequently graduate into each other, in such way as to show that the proximate physical conditions are nearly the same in both"; for "one degree of pressure seems essential to perfect and uniform sleep, while a greater degree, without other alteration of state, assumes more or less the character of disease".‡ While such changes of the circulation in the head are obviously

‡ Ibid. pp. 450-1.

concerned in influencing the functions of consciousness and volition, it is equally manifest that an anæmic state of the vessels is precisely the one calculated to disarm the narcotic of its dangerous properties. But for that anæmic state, the cerebral capillaries might be goaded on by a full dose of opium into fatal coma. The necessity of a healthy amount of congestion and consequent pressure, however essential to the production of sleep, may be inferred also from considerations regarding the nutrition of the organ. "The sleep of animals", Dr. Carpenter tells us, "consists not in a state of diminished energy of the nutritive functions, but in the cessation of the sensorial activity, dependent upon a suspension of the functional power of certain parts of the nervous system, during which there is reason to believe that the nutritive and reparative operations of those organs go on with even augmented rapidity".* The value of sleep in this view, and the importance of a healthy circulation of the materials for nutrition, considering the wasting effects of sensorial hyper-activity in fever, are self-evident.

On witnessing such striking displays of the remedial virtues of opium, as in the case related above, one is fain to break out with Sydenham "in praise of the great God, the giver of all good things, who hath granted to the human race, as a comfort in their afflictions, no medicine of the value of opium, either in regard to the number of diseases that it can control, or its efficacy in extirpating them!" After all, most of its value depends on the discrimination with which it is prescribed. When injudiciously administered, as in sthenic cerebral excitement, or in the improper arrest of diarrhoea in certain states of fever, it has been observed to produce phrenitis, epilepsy, and coma; so also, when indiscriminately prescribed in delirium tremens, its employment has occasionally been followed by apoplexy. Great and marvellous, therefore, as are the virtues of opium in a variety of diseases, and admirable as are its soothing qualities in several of the forms of cerebral disorder in fever itself, yet let no man venture to prescribe it for the latter (whether in large or small doses) in the dark or at random. It is a sharp-edged tool, and of such fearful potency, that, if it fulfils not a curative intention, it will probably destroy life. There is no instance, in the whole range of practical medicine, more imperatively demanding a sure diagnosis. In short, our warrant to prescribe it hinges on our ability to ascertain precisely that condition of the brain which alone will admit of its safe employment.

It was a rare sagacity which led Dr. Graves to employ tartar emetic in combination with opium in those cases both of idiopathic fever and delirium tremens, in which the narcotic would probably stimulate to over-congestion of the brain, but for the depressing action of the mineral on the heart and capillary circulation. This complex practice finds its parallel in the analogous operation of opium in states of anæmia in fever.

Medical science is more advantaged, perhaps, by defining the circumstances to which our known remedies are applicable, than by exploring the resources of nature for others. Not only is great discrimination necessary in deciding on the cases which demand the use of opium, but also in regulating the doses adapted to each variety. Little can be added to Dr. Latham's admirable directions. Our rule of conduct, indeed, is suggested by the degree of sensorial excitement. "Simple wakefulness may be gently lulled to sleep by a few drops of laudanum, but wild delirium requires to be mastered and (as it were) forced into repose by a much larger dose." Opium, however, goes much farther; and, therefore, a much less dose is required in quelling asthenic sensorial disorder, combined with fever, than when it exists alone. Five minims in the milder cases, and twenty in the graver, may be considered minimum and maximum doses in fever. Much, after all, must be left to our vigilance in watching its effects, and to our discretion in judging when to desist, and when and in what doses to repeat the remedy. There are yet other "cases where the indications for the employment of opium are doubtful". We shall describe the variety of sensorial disturbance in fever in Dr. Latham's own words:—

"Wild delirium, and long wakefulness, and a circulation weak and fluttering, seem to call for a considerable dose of opium. Yet, withal, there is a *certain jerk* in the pulse, so that we cannot help suspecting that the blood vessels have something to do with the sensorial excitement. Under such circumstances, I have certainly seen twenty minims of laudanum produce tranquil sleep, from which the patient has awoke quite a new man; but I have also seen the same quantity produce a fatal coma, from which he has never been roused."

Dr. Latham's recommendation, therefore, is, in so dubious a case, to avoid "striking a heavy blow in the dark", and to

administer a small dose at intervals of an hour or two, "so as to stop short of actual mischief at the first glimpse of its approach, or be led by a plain earnest of benefit to push the remedy to its full and consummate effect". Judicious as is this advice, we cannot but think, that on this mode of treatment of cases, in which, on Dr. Latham's own shewing, "the indications for the employment of opium are doubtful", any practice which aims at once to keep down vascular action and soothe the nervous system is a real improvement. And such, we need scarcely add, is the complex method of Dr. Graves.

It only remains that we should revert to the *anæmic* type of sensorial disturbance in fever. In that milder variety of it which, as described by Dr. Latham, we placed in contrast with a much graver form, "a moderate dose of opium", he tells us, suffices to change a state of peril to one of convalescence. But his remarks do not contemplate so frightful a form of anæmia in fever as that of which we have given an example, and which might result equally from a large intestinal, nasal, or bronchial hæmorrhage, as from uterine. He speaks of heroic doses of opium only "in extreme cases of delirium tremens", while twenty minims of the tincture, he asserts, are quite sufficient for the purpose of subduing "the very same symptoms, carried to the greatest extremity, when combined with fever." But while "a moderate dose" suffices to relieve the less urgent anæmic forms of the disease, the case related above as having occurred to my own observation, seems to sanction a bolder practice in the perilous cases of an extremely ex-sanguine condition of the brain in fever, coupled with the exhaustion resulting from protracted sensorial excitement.

ON THE USE OF CHLOROFORM IN OPERATIONS ON THE EYE.

By WHITE COOPER, F.R.C.S. Eng., Ophthalmic Surgeon to St. Mary's Hospital, and Senior Surgeon to the North London Eye Infirmary.

IN common with many others, I for some time hesitated before using chloroform in extraction of cataract, from a fear that the object of the operation might be defeated by the eye receiving injury during the return to consciousness, or by vomiting afterwards. It appeared to me, however, so deserving of a trial, that nearly two years ago I first employed it, and since that time have availed myself of it very frequently in operations on the eye, including sixteen cases of extraction of cataract, nine of artificial pupil, four of foreign bodies in the eyeball, and two of tumours in the globe, besides numerous needle cases. Several of the cases have been published in the *London Journal of Medicine*;* and among the gentlemen who witnessed the more difficult operations, I may mention Mr. Barnard Holt, Mr. W. F. Barlow, Mr. Holmes Coote, Mr. Charles Hawkins, Mr. G. Pollock, Mr. J. R. Lane, Dr. Toogood, etc. Having had this experience, I propose to offer a few observations, which may be found practically useful.

The advantages obtained by the use of chloroform in operations on the eye, are, a perfectly quiescent condition of all the muscles, whether of the globe or the lids, absence of congestion of the eye, and mental tranquillity for the patient. To the operator, the perfect repose of the eye affords a manifest advantage, the various steps of the operation being performed with as much facility as in a demonstration on the dead subject; the risk of prolapse of the iris (which is usually caused by muscular action) is greatly diminished, and the corneal flap can be accurately adjusted.

Under ordinary circumstances, the very act of raising the lid and fixing it, causes a sympathetic rush of blood to the eye; which vascularity is increased during the various stages of the operation. When the patient is unconscious, nothing of the sort happens. I have repeatedly completed the extraction, leaving the eye as free from congestion as before it was commenced; and the same has been noticed by gentlemen who have witnessed my needle operations at St. Mary's.

There is perhaps no operation more dreaded by nervous persons than that of extraction, from an exaggerated idea of the sensibility of the eye. The knowledge that the operation will be performed without the least suffering, inspires such persons with confidence; and the joyous state of mind which all patients experience on awaking from sleep and finding the operation concluded and the eye bound up, is highly favourable for recovery. And now as to the proceedings.

* Carpenter's "Principles of Physiology, General and Comparative", p. 78.

* "Cases of Foreign Bodies in the Eye", vol. iv, p. 301; "On Cysts in the Interior of the Eye", vol. iv, p. 787.

I strongly advise that in operations on the eye under chloroform, there should be at least one competent assistant besides the operator and the administrator of chloroform; each of these has his own department to engage his attention, and it is most embarrassing to have the patient partially recover and struggle just at a critical moment. This occurred in the first extraction under chloroform performed by me; and, as it was the first case of the sort in which Dr. Snow had administered the vapour, the patient had not a sufficient dose. It unfortunately happened that the gentleman who was to have assisted me was prevented keeping his appointment, but I imagined that the doctor and I could manage the lady ourselves: in due time, she appeared completely insensible, but just as the section was being satisfactorily completed, the patient threw her head on one side and tried to sit up; the consequence was, that the operation was impeded, considerable prolapse of the iris took place, and a closed pupil was the result.

The patient should be recumbent. In that posture he can rest quietly after the operation, and is more manageable during the period of excitement than when sitting in a chair. I have tried the administration of chloroform on a handkerchief, and by means of Dr. Snow's apparatus, and decidedly prefer the latter. When the handkerchief was used, it was in my way; and the fumes of the chloroform annoyed me,—matters of importance in such a delicate proceeding as extraction. A full dose of chloroform is necessary, and the patient should not partake of food for five or six hours prior to the operation; but he may swallow a few fragments of ice just before it is commenced, and again as soon as consciousness returns. This (which I believe was first suggested by Dr. Simpson of Edinburgh) allays any tendency to vomit. I prefer operating in the afternoon, as the soporific effect of the chloroform continuing, generally ensures a good night; but the hands must be secured, and the patient carefully watched, as under ordinary circumstances.

With regard to the operation itself, it is important to have the point of the extraction-knife as sharp, and the edge as keen as possible. If there be the least *hanging*, the eye will be pushed before the knife, from the utter passiveness of all the muscles, and unless the operator is prepared for this, there will be great probability of the counter-puncture being made too near the centre of the cornea, whereby the section will be too small.

During extraction, as ordinarily performed, the lid is dropped as soon as the section is completed, and a pause takes place to permit the eye to become quiet. Under chloroform this is unnecessary: there being no spasm, the curette may be used, and the cataract pressed out the moment the section is completed. When the lens has escaped, the eye presents a curious appearance, always supposing enough chloroform has been administered; the muscles being passive, the iris falls back in a concave form, and the cornea having no support, sinks, becoming as wrinkled as a shrivelled apple. The eye having been gently cleansed, and the lids dried with a soft rag, the upper lid should be lifted by the lashes and brought down over the cornea; then two broad strips of adhesive plaister should be crossed over the eye and cheek, a bandage applied, and the patient left quiet for half-an-hour or an hour, after which he can be removed to bed. When all fear of vomiting has subsided, the plaister may be taken off: but it must be thoroughly softened with warm water, and lifted with the utmost caution and gentleness, so that there be no dragging on the lids. The subsequent proceedings differ in no respect from those practised after the operation as ordinarily performed.

In these remarks I have especially mentioned Extraction, but the general directions are equally applicable to all operations on the eye; and I may add, in conclusion, that when operating on an eye in a state of inflammation, as in the extraction of a foreign body, a shot, a fragment of steel, or copper cap, the value of chloroform cannot be too highly estimated.

12, Berkeley Square, November 1852.

ON FIXED AND LONG-CONTINUED PAIN IN BONE.

By HENRY LEE, F.R.C.S. Eng., Surgeon to the Lock Hospital, Assistant-Surgeon to King's College Hospital, etc.

In the concluding volume of the *London Journal of Medicine*, I ventured to offer some observations on, and to relate some cases of, fixed pain in the tibia, which had been relieved by perforating the bone with a trephine. The cases appeared

naturally to divide themselves into two classes, namely, those in which the pain depended directly upon the pressure of confined matter, and those in which some other source of irritation, situated within the bone, had kept up a chronic inflammation of the part.

The following case, which has since come under my care, appears especially interesting, as partaking of both the above forms of disease; the pain having fixed itself in the part before there was reason to suspect the formation of matter, and having continued for some time after the pressure of the confined fluid was artificially relieved.

An apology will scarcely be wanted for drawing attention to the details of such cases, as the utility of surgical interference is far from being universally acknowledged. Even in a work of much authority, by a distinguished professor of surgery in Edinburgh, as late as the year 1847, we find it stated that the cases where the operation of trephining the tibia is necessary, must be extremely rare, as no case had presented itself to the professor's notice during a long and extensive practice.

CASE. During the last summer, a gentleman of a highly nervous temperament applied to me, having suffered, for between two and three years, very severe pain in his left leg. At that time there was an oval swelling over the centre of the tibia, evidently depending upon an enlargement of the bone; and about three inches lower down, was a second smaller projection, apparently of the same nature. The bone in both these places was very tender to the touch, and the upper enlargement presented at one point a sense of fluctuation, as though a small quantity of fluid were contained between the periosteum and the bone. The necessary examination of the leg was followed by a considerable increase of aching pain. When requested to point out the part where he experienced most suffering, he would pass his hand generally over the lower part of the tibia, but would not point out any one spot as habitually more painful than the rest. He however thought that the upper swelling was more sensitive at night, and the lower one during the day when the leg was hanging down. He stated, that twelve years previously, he had taken large quantities of mercury for an affection of the throat, which there was no reason to believe was of a specific character. At that time his mouth was kept sore for five months, and he took occasionally as much as twenty-five grains of blue pill a day. Six years after this he had the small-pox, which left him much debilitated.

In the year 1849, he became subject to a very severe cough, for which he consulted Dr. Golding Bird, and there was reason to believe that a small cavity had formed in one of his lungs.

During the early part of the following year his ankles became swollen, and a pain settled in his left shin. About a fortnight after the first appearance of the pain, he struck his leg severely. The pain then became suddenly increased, and continued without intermission for many weeks. At length, the pain in the leg subsided, and he passed three months in tolerable comfort; after this, however, all the former symptoms again returned, in consequence, as he supposed, of having taken a very long walk.

In the spring of the year 1851, the leg was struck a second time, and the pain then became of a much more severe character than it had previously been. From this period the pain was so severe as to prevent his sleeping at night. Between six and eight o'clock in the morning, the limb generally became bathed in perspiration, and he would then fall asleep. This was the only rest he got, except when under the influence of the iodide of potassium, which had been prescribed for him by Dr. Golding Bird. After he had taken five or six doses of this medicine, his pain was usually relieved, and he slept tolerably well; but as soon as it was discontinued, the pain returned with all its former severity. Not wishing to take the medicine unnecessarily, he tried more than once to do without it, and had, under these circumstances, passed as much as a month without any sleep, except the short nap that he got between six and eight o'clock in the morning. He was, therefore, driven latterly to have almost constant recourse to his medicine, and took from eighty to a hundred grains of it a month. At length he found, although the pain was relieved, that his gum-became spongy and apt to bleed, and in other ways it became apparent that the continued action of the medicine was exerting an injurious effect upon his system. It was under these circumstances that, with Dr. Golding Bird's concurrence, he came to me to ascertain whether any more permanent relief could be afforded by surgical means.

The existence of pain in the part previous to the reception of the first injury, the tenderness of the bone, and the evident

affection of the periosteum, rendered it probable that this was not an ordinary case of abscess in the tibia. Having shortly before had a somewhat similar case, in which the pain was relieved, although a very small quantity of matter was evacuated, I recommended that the tibia should be trephined.

The operation was accordingly performed on the 27th of September. The patient having been rendered insensible with chloroform by Dr. Snow, a trephine, five-eighths of an inch in diameter, was applied over the centre of the larger projection about the middle of the tibia. The surface of the bone was here found to be soft, but its substance was hard as ivory, and it was with much difficulty that the trephine was made to perforate it. The original cavity of the bone was found to be occupied by dense bony structure, so that a cylinder of solid bone, an inch in depth, was removed, without any cavity or cancellous structure being exposed. The centre of the portion of bone thus removed was found, when subsequently more carefully inspected, to be softened to a very limited extent.

A smaller trephine, three-eighths only of an inch in diameter, was then applied over the second projection lower down upon the tibia. The bone here was much softer, and before the instrument had penetrated half an inch, a small cavity was opened containing some thin brownish-looking matter. This cavity was examined with a probe, and extended a little way up the centre of the bone.

The smaller trephine was now again applied about midway between the two former openings. The bone here was softer than in either of the other situations, and the instrument entered its substance readily. It had penetrated about three-fifths of an inch, when a considerable quantity of reddish matter oozed up by its side, and the trephine entered a distinct cavity in the bone; a probe introduced through the aperture passed up to the neighbourhood of the first opening made by the larger trephine. This was therefore enlarged, and a communication established between it and the opening last made. The cavity exposed by the second application of the trephine appeared not to communicate with the other. Had it done so, the matter would have passed through it, and not have been forced up by the side of the trephine when applied the third time. The two collections of matter, in all probability, corresponded to the two distinct injuries which the part had sustained.

For some days after the operation, the patient suffered severe pain in the leg, but nevertheless occasionally got some natural rest at night. On the 2nd of October, he for the first time experienced an interval of complete ease. The pain, when it recurred, had now changed its character. It was rather an excessive smarting than the dull aching sensation formerly experienced.

On the 6th of October, the pain from which he had so long suffered had entirely subsided, but he complained of an increase of the smarting sensation upon the surface. He was directed to apply some flannel sprinkled with chloroform over the leg, but experienced little relief from its use. On the 7th, he had some remission from the smarting pain, but it returned again on the 8th. On the 9th, he continued tolerably easy, but the pain again recurred on the following day. On the 11th, a fortnight after the operation, he was free from pain, and slept well, although the parts were still tender to the touch. On the 19th and 21st of October, he continued free from pain.

This patient continued under observation during the month of November, after which he left town. There had been no return of pain at that time, the swelling of the leg had gradually subsided, and he slept soundly at night without any medicine. There was every reason to believe that he was permanently relieved of a complaint which had for so long a period caused him so much suffering.

In cases like the preceding, where a continued pain fixes itself in a bone, and where its nature cannot be satisfactorily ascertained from the symptoms, an exploratory operation may be necessary. The interior of the bone may be occupied either by pus, or by some more solid morbid deposit, or by scrofulous matter, or by a piece of necrosed bone. In such doubtful cases, I have been led to prefer, in the first instance, a trephine of a small diameter to one of a larger size. A portion of bone is by this means more quickly removed, and the opening made more readily heals. Should the first application of a small trephine not discover the disease, a second or a third opening may be made in the bone without inconvenience.

The accompanying wood-cuts (which were introduced to illustrate some other points, in a paper in the *London Journal of Medicine*) will show how advisable it may be that in some cases the crown of the trephine should be applied over a very

limited surface, and in others, how necessary it is to use the instrument a second time.

Fig. 1. Abscess in Tibia, opening into knee-joint.

Fig. 2. Abscess in upper end of Tibia, containing putrid pus and dead bone; trephined unsuccessfully. The cavity lined by a dense membrane.

In determining the precise spot at which the trephine should be first applied, the most projecting and most sensitive point is to be selected. But it will sometimes happen that a considerable portion of bone is equally enlarged, and that no one part is particularly tender to the touch. A slight increase in the temperature of the skin, which can be appreciated by the touch, will then in some cases indicate the proper situation for the operation.

13, Dover Street, Piccadilly, Nov. 1852.

CLINICAL REMARKS UPON THE EFFECTS OF THE BATH THERMAL WATERS IN THE TREATMENT OF CHRONIC RHEUMATISM.

By JAMES TUNSTALL, M.D., Physician to the Eastern Dispensary of Bath, and formerly Resident Medical Officer of the Bath General Hospital.

I AM perfectly aware that, in bringing under the notice of my professional brethren the good effects of a course of the Bath waters, in the treatment of Chronic Rheumatism, I run the risk of being accused of telling a thrice-told tale; it will be said that every medical man knows that these waters have been unduly celebrated, and that at present they have no reputation whatever: this, however, has been the case in reference to all our British springs. I hold it to be a duty to the profession, that those who practise at our Spas, should occasionally bring forward the result of their practical experience in the employment of these valuable remedies. I am persuaded that much

of the discredit cast upon our native springs, and the extraordinary virtues attributed to those in other countries, has arisen, in a great degree, from the fact, that British physicians have hesitated to make use of the abundant materials at their command. This omission arises, in a great degree, from the very natural, but, I conceive, mistaken notion, that, by so doing, they would incur the suspicion of writing to advance their own individual professional renown. The result of this diffidence has been, that patients are in the present day sent to Germany to procure that relief which their predecessors obtained at home; and this disinclination to impart a knowledge which only experience can supply, has led to a comparative ignorance on the part of British practitioners, not only of the chemical qualities of our native springs, but also of their effects in the treatment of disease. Such neglect of these remedial agents does not obtain abroad: there every physician is in some degree acquainted with the composition and mode of action of the various mineral waters; the literature of the profession is rich in works upon the subject, and the crowded state of the various watering places shows the importance ascribed to them in continental medicine.

Dr. Fuller, of St. George's Hospital, in his valuable work on Rheumatism, Rheumatic Gout, and Sciatica, just published, thus alludes to this subject:—"The vast importance of the total change of scene and air consequent on a visit to the English or continental watering-places, can hardly be over-estimated: a new stimulus is imparted to the system, the organic functions receive an impulse which cannot be imparted to them in any other way, and remedies which have proved unavailing at home, very shortly become active agents for good. . . . Observation has convinced me, that he who is tormented by rheumatic gout in a chronic form, will usually experience more relief from a month's residence at Bath, than from a much longer sojourn at any other watering-place." My own experience fully corroborates these remarks of Dr. Fuller.

It will readily be admitted, that acute rheumatism, while it is one of the most common, exceeds almost all the ordinary febrile affections, in the protracted character of its convalescence; while the amount of permanent loss of power and deformity which usually attend it, render it one of the most intractable and unsatisfactory diseases. It may indeed be said to become chronic by wearing itself out; the patient's strength and vital power being reduced to a state of debility scarcely permitting inflammatory action.

If we are called in to see a patient in the first stages of chronic rheumatism, we see that a general want of tone pervades the chylipoietic viscera; the circulation is languid, the blood vitiated and carbonized; the secretions of the skin and kidneys are changed in their sensible appearance and chemical character; the muscular and fibrous structures gradually becoming impeded in their functions, deposits of extraneous matters, solid and fluid, take place in the neighbourhood of the joints, with a slowly progressing contraction of the muscular fibres of the extremities, and great nervous debility.

The object of my present remarks is to show that, in the Bath waters, we have a remedy, which possesses the power of arresting the further progress of an insidious malady, by improving the patient's general health and bodily powers. Before I proceed to this part of my subject, let us, for a moment, inquire what circumstances give rise to these *sequela*—a very great portion of which occur after the more acute symptoms have been subdued, and the practitioner has taken leave of his patient.

We have undoubtedly many preventible causes in action. How useless it is to advise our patient to move about and use his limbs, if he has been for weeks confined to his bed in a constrained position! It would be as absurd as for a surgeon to allow the lately fractured arm to remain in a sling, after perfect bony union had taken place; our duty in either case is to direct passive motion, until the strength of the patient enables him to move the limb himself. In the same way that the surgeon, after a fracture, restores the use of the fractured limb, by graduated exercises, both active and passive, so ought the physician, in the convalescence from acute rheumatism, to see the use of the limb restored as much as possible, and not permit his patient to produce rheumatic anchylosis, by bandages and other contrivances, without a warning; or to cripple along upon crutches because he has neither the will nor energy to persevere in the recovery of his limbs by the use of moderate exertion. Far better is it to cross the room by the help of the chairs and table, than to drag through a weary mile, bandaged up, on crutches.

In the treatment of gout and chronic rheumatism, there are many evils to contend against. I have said that numerous pre-

ventible causes combine to produce morbid effects. Thus, the practitioner is consulted by a patient, exhausted in nervous energy by the long continuance of disease, incapable of the least exertion, and too enervated to perceive its necessity; a case in which active remedies, general and specific, have ceased to produce good effects; where opiates and other sedatives, useful in the earlier stages, are now productive of mischief: he sees with regret the habits of the sick room, its improper diet and stimulants still forming a part of the daily routine of a passive existence: the patient complains to him of enlarged, tumefied, and painful joints, loss of appetite, and sleepless nights.

In such a case, what is to be done? He prescribes a tonic, and orders gentle movements of the affected limbs. His medicines are regularly administered, but his directions are not complied with, from the fear of producing pain: the case gradually approximates to complete loss of power in one or more joints; then anxious to abolish the associations of the sick room, he advises his patient change of air.

Now I am inclined to attribute much of the suffering in these unfortunate cases to the patient's extreme nervous debility, producing a disinclination to convalescence: in other words, that the partial immobility induced by the acute attack, has engendered a fear in the patient's mind lest movement should reproduce pain and inflammation. This fear is shared and encouraged by nurses and attendants, who, instead of assisting the patient to leave his recumbent position, and move his limbs, do all in their power to render it unnecessary, and thus, by mistaken kindness and pitying solicitude, aggravate sufferings which they are most anxious to alleviate.

It is in these cases that the Bath thermal waters produce such beneficial effects. The immersion of the whole body in a warm, tonic, and exhilarating fluid, highly charged with carbonic acid gas, in a bath of sufficient capacity to permit free muscular motion, soon restores the nervous energy, improves the quality of the blood, and, by promoting the circulation of the capillary vessels, strengthens the joints, and restores muscular vigour. The salts which these waters contain are peculiarly grateful to the dyspeptic stomach; the iron, from its extreme subdivision, is, I make no doubt, completely taken into the circulating system, so that while their internal exhibition improves the biliary, renal, and cuticular secretions, they produce little or none of the usual effects of iron upon the alimentary canal.

As I do not desire to overburthen these remarks with cases, I shall select two only from my note-book, as types of those in which this treatment proves successful.

CASE I. Mr. P. T.—, aged 25, came to Bath in October, 1850, having had an attack of acute rheumatism in the previous June. At this time there was considerable lameness in the right lower extremity, with enlargement and stiffness of the ankle joint, the patient limping along by the aid of a stick. The limb, in walking, was perfectly straight, from the want of the *voluntary* effort to use either the knee or ankle. Satisfying myself that the heart was unaffected, and that the lameness proceeded in a great degree from the habit acquired in the early period of his convalescence, I directed him to abstain altogether from walking abroad, until he could cross his chamber without his stick. I ordered him to drink the waters at their source twice a day, and to apply the hot douche to his limb three times a week. In a month he returned to London, perfectly recovered.

I have but few remarks to make on this case, but I feel persuaded, that had he remained at home, no treatment, however judicious, would have been successful. The use of the limb would have been lost for the want of the voluntary effort; nay more, had he continued his crippled gait a few weeks longer, permanent lameness would have resulted; for nature will pursue her vital actions, and if, after rheumatic inflammation has been subdued, motion is restricted or suspended, the natural secretions become excessive, from not being required for their legitimate functions. Thus, in this case, the tendons of the posterior surface of the limb would have become contracted, and the ankle joint the seat of a permanent rheumatic deposit, in consequence of the whole work of the limb being thrown on the anterior femoral muscles.

CASE II. Mr. B.—, aged 61, a farmer from Devonshire, consulted me on the 11th of June, 1851, stating that he had had repeated attacks of rheumatic gout, which had entirely deprived him of the use of his lower limbs, so that he could only move from room to room by means of his hands and knees. The patient was of the lymphatic temperament; his nervous system was greatly depressed from long continued disease. The circulation, however, was regular, but languid. I examined him in

the recumbent position, and found that he could, in that position, freely move his limbs, which were free from contractions or gouty deposits. I could detect no pain nor tenderness in the spine, nor any evidence of internal structural malady. The bowels were in good order, the urine healthy and secreted in proper quantity, the appetite good, and digestion well performed.

My opinion of the case was, that it was one of extreme nervous and muscular debility, produced by a perseverance in the use of *colchicum*, long after the more acute symptoms of gout had been overcome; that in fact it was a complication of arthritic disease with slow, narcotico-irritant poisoning. I advised him to bathe three times a-week, and to drink the waters twice daily at the spring. I put him upon a generous diet, and ordered him to spend several hours daily in the open air, and to abstain altogether from medicines. He continued this plan until July 12th, at which time he was able to stand with the assistance of the table, and to walk a few steps supported by two persons. I then directed him to go to the sea-side for six weeks, and to return to Bath in September. He returned greatly improved in every respect, and again commenced the use of the waters, obtaining so much benefit, that on the 31st October, he returned home perfectly recovered.

This, though a severe case, is but the type of many frequently met with in this city, in which the long perseverance in the domestic use of *colchicum* produces so complete a prostration of strength, that to move a limb, or even change the position in bed, is attended with fainting fits and profuse perspiration. I remember many years ago, a case in which sudden death occurred from syncope caused by the long-continued use of this remedy, which being easily obtained, and much commended for its specific effects, is constantly taken by many gouty persons as an innocent remedy.

To show how completely we may be foiled in our diagnosis, by this pernicious practice of domestic medication, I will here mention a case which came lately under my notice.

I was consulted a few days since by a gouty subject, who complained of chronic pyralism accompanied by several anomalous symptoms, for which at first sight, I could assign no sufficient reason. Upon questioning him closely, he told me that for two years past, he had been in the habit of purchasing *potassii iodidi* 3j, which he dissolved in a pint of water, of which he had during the whole of that period taken a wineglassful twice a day, he having been recommended to try it by a neighbour.

It is this indiscriminate medication that environs the Bath thermal treatment with so many difficulties, and which not unfrequently brings discredit on the springs themselves. I last week met a medical gentleman, who told me he was taking three doses daily of *colchicum*, and was then about to take a bath. I am fully persuaded, that if we wish the waters to produce good effects, their judicious employment requires no medicinal interference; and that they are a very powerful remedial agent in the hands of the physician, whose duty it clearly is to watch their effects in the same way that he would those of any other medicine, and not by over-anxiety for his patient's recovery, to interfere with them by prescribing remedies often useful alone, but incompatible with the rational employment of the Bath waters.

Bath, December, 1852.

ON THE SOURCE OF HÆMORRHAGE IN CASES OF PARTIAL SEPARATION OF THE PLACENTA.

By F. W. MACKENZIE, M.D. Lond., Fellow of University College, etc. etc.

THE precise source of hæmorrhage in cases of this description, whether from the uterine or placental surface, does not appear to have been very accurately ascertained. By some authorities, it is believed that the blood flows exclusively from the great venous and arterial openings in the lining membrane of the uterus, which are laid bare by the separation of the placenta; by others, that the discharge issues principally or entirely from the vascular openings which exist on the exposed surface of the placenta; whilst others regard the hæmorrhage as having its origin partly in the maternal and partly in the placental surfaces. The following quotations from writers of acknowledged celebrity will confirm the general accuracy of this statement, and explain the motives which suggested the investigation, the results of which it is the more immediate object of this paper to make known.

"It is," observes Dr. Robert Lee, "from the great semilunar,

valvular-like, venous openings in the lining membrane of the uterus, and of the arteries which are laid open by the separation of the placenta, that the blood alone flows in uterine hæmorrhage."—*Lectures on Midwifery*, p. 361.

In criticising the opinion, that the hæmorrhage comes from the exposed placental surface, and the statement of Dr. Simpson, that he knows no reason, anatomical or otherwise, for alleging that the open placental orifices do not bleed, Dr. Ashwell remarks:—"It would have been well if these orifices and their capacities had been demonstrated. I have never yet seen them, although I have subjected numerous placentæ to examination, both before and after injection; nor have I been more successful when I have carefully peeled off an adherent placenta after death. It is, on the contrary, easy enough to show to the satisfaction of the most incredulous, the great openings existing in the lining membrane of the uterus, exactly opposite the attachment of the placenta, and which are covered by interposed decidua. Into many of these, the tip of the finger may be inserted, while their course and extensive communications with the uterine sinuses, full of blood, is evident at a glance. Surely, such an organization affords the clearest proof of the source of the hæmorrhage in placenta prævia. By some unfortunate accident, the placenta and the intervening decidua are detached, and as the uterus is full of blood, there is no barrier to prevent its escape; in moderate amount if the detachment be slight, but excessive in quantity if the separation is considerable and attended with excitement and hurry of the heart's action."—*Medical Gazette*, Nov. 7th, 1845.

"That the blood is not poured out of the placenta," says Dr. Chowne, "is obviously suggested, by considering what the effect upon the child would be, of profuse hæmorrhage derived from those vessels upon which the sustenance of the ovum depends. Hæmorrhage occurring under such circumstances, the child would be subjected to a two-fold privation. First, in being abridged of its natural supply by a quantity equal to all that should be furnished to it through the detached portion; and, secondly, in the exit and waste of even that curtailed quantity which enters the placenta by the attached portion, and is by some supposed to make its escape by the detached portion. Reverting to the terrible hæmorrhages that sometimes take place while the child remains secure, and is born even vigorous and strong, I am led to regard the sufficient way in which it is nourished as evidence, that the blood effused is not poured out of the placenta."—*Lancet*, August 28th, 1847.

In opposition to these views, we have the following opinion expressed by Dr. Simpson. "I know of no reason, anatomical or otherwise, for alleging that the open placental orifices do not bleed; and, on the contrary, I believe with Dr. Hamilton and others, that the discharge issues principally or entirely from the vascular openings which exist on that exposed placental surface. In cases in which the placenta is partially and repeatedly detached before labour begins, (as happens frequently in placental presentations,) before each attendant attack of hæmorrhage is arrested, the vascular system of the separated portion of placenta seems to require to become blocked up and impervious, with coagulated and infiltrated blood. This obliteration of its vascular cells prevents the further circulation of maternal blood through the detached part of the organ, and hence prevents also the further escape of it from its exposed surface. Each new detachment gives rise to a renewed hæmorrhage, which again ceases on the sealing up of the vascular system of the detached part. . . .

"In common cases of unavoidable hæmorrhage, the amount of the attendant flooding seems to be as much regulated by the quantity of placental surface still remaining attached to the uterus, as by the quantity already separated from it; the degree of flooding depending as much or more upon the extent of the means of supply of blood, as upon the extent of its means of escape. And in proportion as we approach nearer and nearer a total separation of the placenta, the number of its afferent utero-placental vessels is diminished, till at last, we find that when the one organ is once completely separated from the other, the flooding is instantly moderated, or entirely arrested; for the placenta ceases to yield any discharge of maternal blood, as soon as its own supplies from the maternal system are thus cut off by the dissection of all its organic and vascular attachments with the uterus."—*Medical Gazette*, Oct. 10, 1845.

The third opinion regards the hæmorrhage as having its origin, partly in the uterine and partly in the placental surfaces. On this point the following authorities may be quoted.

"In all cases of floodings," says Dr. Radford, "which occur during the latter months of pregnancy or in labour, several effects are produced by this accident: firstly, the utero-pla-

central vessels are lacerated; secondly, the large venous openings are exposed; thirdly, sometimes, and indeed, not unfrequently, there is laceration or disruption of the placental structure, whereby the ramifications of the umbilical arteries and veins are more or less torn through. There are, then, always two surfaces exposed, upon each of which vessels are laid open, which sometimes pour out blood in such torrents as to deluge the bed, and the floor of the room, and places the life of the woman in the greatest jeopardy, and, indeed, sometimes destroys her by the first gush. When the placenta is only partially separated, the blood which is lost, is chiefly venous, and mostly comes either directly from the great venous apertures, or indirectly in its course from the placenta. . . . But, when the organization of the placenta is broken into" (as it is argued is the case in *Placenta previa*), "the blood now comes from the foetal vessels, and cannot long flow without causing the death of the child."—*Lancet*, Feb. 27th, 1847.

"Let us suppose a case," Dr. Murphy observes, "in which the placenta is completely attached to the mouth of the uterus, and that labour has just commenced: what takes place? The first effect of the pains must be to break the vessels passing from the margin of the os uteri into the maternal portion of the placenta. The curling arteries of the uterus are closed by coagula formed in their torn coats; they cannot, therefore, pour out much blood; such is not the case, however, with the large uterine veins when they are broken across: one fragment is an opening that communicates with the large net-work of veins in the uterus; the other leads directly into the cavernous structure of the placenta: through both these orifices blood may be discharged, being in the former case venous blood, flowing in a contrary direction to its course from the uterus, and in the latter, arterial blood, passing directly through the cavernous structure of the placenta, and escaping from the broken openings on its surface."—*Lectures on Midwifery*, p. 331.

These quotations need not be extended; the foregoing are sufficient to show that the opinions of obstetric pathologists by no means coincide in regard to the source of hæmorrhage in placental separations, and doubtless this discrepancy of opinion has in a great measure tended to those very opposite rules of practice which have been inculcated by different writers. It occurred to me, that some light might be thrown upon this question by selecting an animal, the organization of whose placenta approximated nearest to that of the human female, exposing the uterus at the full period of gestation, and detaching portions of the placenta, so as to observe the actual source of hæmorrhage. This experiment I was enabled very satisfactorily to perform with the kind assistance of Mr. Marshall, of University College Hospital, and the following particulars comprehend a summary of the facts which were observed.

A large pregnant bitch, which it was calculated was within two days of the full period of gestation, was placed under the influence of chloroform, and the uterus was then fully exposed by an incision, made in the course of the linea alba, from the sternum to the pubes. The uterine tissues were now carefully divided over one of the placenta; and at right angles with this incision another was made along the border of the placenta, so as to admit of an easy separation of the two organs. It was observed, that the portion of the uterus in apposition with the placenta was highly vascular, and bled freely upon being divided; this, however, soon moderated, and then the separation of the placenta was commenced. The moment it was begun, profuse hæmorrhage, of a bright arterial colour, took place in a continuous stream from the uterine surface, which had been previously adherent to the placenta. No bleeding whatever took place from the placental surface; and on continuing to detach further portions of the placenta, it was observed that each successive detachment was attended with increased hæmorrhage from the uterus, but none from the placenta. In due time, the placenta was entirely detached, but the blood still continued to flow from the uterine surface only.

A second observation was now made with another placenta, and with the same results. No hæmorrhage whatever was observed to take place from the detached placental surface, whilst blood poured profusely from the uterine, increasing as the detachment continued.

In a third instance, the placenta was abruptly torn away from the uterus, but blood continued to flow freely from the denuded uterine surface after the separation.

In a fourth case, the placenta, foetus, and membranes were together removed from the uterine cavity. The investing portion of the uterus contracted immediately on their removal, but still a large quantity of blood was poured out from that portion of its interior to which the placenta had been attached.

The following observations were also made in the course of this experiment, which it may not be uninteresting to subjoin. i. On detaching the placenta from the uterus, a number of white, elastic, filamentous-looking bands were observed to pass from one organ to the other. These were probably the utero-placental arteries: they were easily torn across, and their divided extremities would seem to close up and retract immediately upon being divided, as their orifices were not afterwards perceptible, nor did any blood issue in jets from the denuded uterine surface. ii. The blood, as I have remarked, which came from the uterus, flowed in a continuous stream, and was of a bright arterial colour. iii. Except from the divided edges of the uterine wound, and the denuded lining membrane of the uterus, no blood escaped from this organ. iv. Although no hæmorrhage came from the detached surface of the placenta, whilst the organ was entire, it was yet found on tearing or lacerating it, while it was partially adherent, that blood flowed from the torn or lacerated parts; but this was to a very inconsiderable extent, and instead of being of a bright arterial colour as was that which flowed from the uterus, it was of a dark purple or bluish tint. It should be added, that each foetus was alive during these observations, and continued to live for some time afterwards.

Thus it would appear in the canine species, that the source of hæmorrhage, in cases in which the placenta is partially detached, is exclusively the denuded uterine surface, so long as the placenta is entire; that the blood escapes in a continuous stream, and is of a bright vermilion tint; that no blood comes from any other part of the interior of the uterus; and that although a certain amount of blood may escape from the placenta, if lacerated or torn while still partially adherent to the uterus, this is comparatively small in quantity, and of a dark venous character.

How far these observations apply to cases of partial separation of the placenta in the human subject, is a question to which we can scarcely give a positive answer, until the structure of the placenta of the bitch has been further examined, and compared with that of the human species: more particularly as regards the disposition of the blood-vessels in its maternal portion. We know, for instance, that in the human placenta, the utero-placental arteries open into large cells formed by the inner coat of the vascular system of the mother, and that between these a free intercommunication exists; whereas in the bitch the venous vessels of the maternal part of the placenta do not constitute a cellular or cavernous structure, but in form and distribution resemble ordinary veins. It remains then to be ascertained, before the value of these observations can be determined, whether there be a free lateral communication between these veins throughout, so as to permit the blood injected into them, where still connected with the uterus, to escape at the place where they have been opened by detachment.

Whilst, therefore, I regard these experiments as interesting in themselves, and as affording, in the general analogy which subsists between the structure of the placenta in the two cases, some support to the doctrine that these hæmorrhages have exclusively a uterine origin, I must not be understood to affirm, that they are positively conclusive on this point. As I have already remarked, some further investigation into the structure of the placenta of the bitch is necessary, to enable us to assign to them their true value and significance. This I propose to undertake; and I will communicate the results in a supplementary paper.

Chester Place, Hyde Park Gardens, London, December, 1852.

PECULIAR CASE OF ACCIDENTAL UTERINE HÆMORRHAGE.

By I. HARRINSON, Esq., Surgeon.

(Read before the Reading Pathological Society, Oct. 27, 1852.)

ON Sunday, July 11th, 1852, at half-past 11 o'clock, a.m., I was called to Mrs. G—, Queen's-road, aged thirty-six years. She was a well-developed woman, having tolerable health, and was about seven and a half months advanced in her third pregnancy. She had suffered less during the present than her former pregnancies.

From her distressed condition, I could only gain the following particulars as to the method of her seizure. She was sitting in her kitchen, between 9 and 10 o'clock, a.m., preparing some culinary compound, when she suddenly felt faint; her bowels were twice moved in quick succession, and severe pain in the ab-

domen immediately succeeded. At half-past 10 o'clock I found her lying on a sofa, complaining of faintness and of extreme pain in her abdomen. She fancied that labour was coming on. There was no discharge. Some brandy was given, and she rallied. I requested that she should be got to bed, and promised to see her again in an hour.

On my return, she was more distressed, more faint, and in more pain; in a few words, she was in a state of collapse.

On examination externally, the abdomen was very tense, and the seat of pain was principally at the fundus of the uterus, which reached and occupied the epigastric region. The pain was that of distension, of bursting, and indescribably distressing.

On examination *per vaginam*, I discovered the cervix uteri not obliterated, the os uteri just admitting the finger, the membranes unruptured, and the head presenting.

Amid the enveloping agony, she was now and then slightly conscious of the pains of labour.

I determined at once to rupture the membranes, which was readily accomplished. The waters flowed profusely and clear; there was not a trace of blood. About this time she had a convulsion, during which life appeared to be all but extinguished.

Dr. Cowan now saw her, soon after 1 o'clock, p.m. After a careful examination, we agreed that a grave accident had happened, but could not determine its precise nature, nor its seat; nor whether it was perforation or rupture of some abdominal or pelvic viscus.

From, however, the condition of pregnancy, and the absence of any other recognized disease, we felt justified in thinking that the uterus must be the organ involved, and that rupture, partial or complete, of that organ had probably occurred.

The indications appeared to be, to relieve the pain, and to keep up the failing powers as well as possible, which were attempted to be fulfilled by opium and by brandy. One drachm of tincture of opium was given immediately, and brandy and water at frequent intervals. There was an almost incessant cry for cold water, which was ungrudgingly supplied.

Three o'clock, p.m. Much the same; no relief. The same dose of tincture of opium was repeated. The os uteri was progressively dilating.

At 5 o'clock Dr. Cowan again visited her. I proposed that we should spare her little remaining strength, by now completing labour with the perforator and the forceps; premising, of course, that that could be done readily and with safety. Dr. Cowan agreed. The head was perforated and extracted with little difficulty. In a short time, one hand being kept firmly applied to the abdomen, the body readily escaped. Without waiting to separate the child, the hand was still kept on the abdomen, and I was surprised to find that it had scarcely diminished in size or in tension.

Firm pressure was kept up, and I was about to observe to the nurse that we had one or two more children to come, when one of the most fearful gushes took place I ever witnessed. Placenta, clots and fluid blood, to the amount of some quarts, were expelled at the same instant. The uterus was at once carried down into the pelvis, and there fixed with the hand. There was no further escape of blood. The uterus showed no disposition to relax, nor did it apparently in the slightest degree.

She was immediately relieved of that dreadful feeling of distension, and lay easy for a time. Anticipating what was to follow, while I was guarding the uterus, the nurse was employed in giving as much brandy and water as she could get down. Another drachm of tincture of opium was given. It was now about half-past six o'clock. After a short time the restlessness increased; she tossed about incessantly, and the extremities became cold. At eight o'clock she apparently fell into a quiet sleep. At half-past eight o'clock, Dr. Cowan again saw her. It was agreed to let her sleep a little longer. She slept, but it was the sleep of death. At ten o'clock her breathing was observed to change, and in a few minutes she died, twelve hours from the time she was first seized.

Autopsy performed next morning. Dr. Cowan was present. The uterus was found well contracted: no blood was discovered within it. No appreciable disease in any organ.

I may here remark, that the cord was twice round the neck of the child, and was very short. I much regret that I did not measure it. There was no disease of the placenta.

What occurred, then, to produce so lamentable an accident, undoubtedly was, a sudden separation, probably nearly entire, of the placenta from the uterus; and the only discoverable cause, an unusual shortness of the umbilical cord, and that twisted round the neck of the infant.

In the retrospect of such a case, a few points present themselves for consideration. Could a more accurate diagnosis have

been arrived at? and if so, could the treatment have been materially modified?

To describe her condition in a few words, it may be said, that she was in a state of collapse, with extreme pain. These symptoms, however, would equally belong to perforation or rupture of any of the abdominal or pelvic viscera, or even to the rupture of an aneurism.

The only characteristic I could name, would be the state of the abdomen. It was distended to the utmost; was dull on percussion; and had an unusual, peculiar, doughy feel.

Her strength was supported after the most approved methods, and opium, that sustainer of the vital energies, was carefully administered. Labour was accomplished as soon as the state of the uterus allowed. When the uterus was emptied, no further discharge was permitted.

No example at all similar has occurred to me before. No writer that I can find has described one exactly corresponding; and some authors do not even name the possibility of such an occurrence. Dr. Robert Lee, in his "Clinical Midwifery", Dr. Copeman in "Crosse's Midwifery", Drs. Churchill, Ramsbotham, and Blundell, etc., give good cases and descriptions of "*accidental uterine hæmorrhage*", as ordinarily happening; but I can find no author giving an account on the diagnosis of such cases as the one related, where no discharge appears externally.

Reading, October, 1852.

BIBLIOGRAPHICAL NOTICES.

THE NATURE, SYMPTOMS, AND TREATMENT OF CONSUMPTION: being the Essay to which was awarded the Fothergillian gold medal of the Medical Society of London. By RICHARD PAYNE COTTON, M.D., Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton. pp. 286. London: 1852.

DR. COTTON'S object has been to present a practical exposition of phthisis, derived from personal observation. His work is divided into three parts, severally treating of (1) the Nature; (2) the Symptoms; and (3) the Treatment of Consumption.

I. NATURE OF CONSUMPTION. In chapter 1, Dr. Cotton points out the relation of phthisis to tubercle as that of cause to effect. By the term phthisis he understands a peculiar morbid condition, which involves, among other consequences, a tubercular state of some of the internal organs. This view he believes to be of great practical importance; for it is the *phthisis* that destroys life; and it is this which must be met by remedies. Of the intimate nature of phthisis, we know very little; but Dr. Cotton dissents from the opinion that it is a poison-disease, and also denies that it possesses any contagious property.

In chapters 2, 3, and 4, we find the following subjects treated of: Mode of Origin, General Characters, and Minute Structure of Tubercle; the Situation of Tubercle; and the Curability of Consumption. The author, allowing the *possibility* of a cure in the last stage of phthisis, believes that in most of the supposed cures, there is merely an arrest of the disease. He has no doubt that recovery may take place in the earlier stages, by removal of the tubercular deposit, or by calcareous transformation.

In chapter 5, the Identity of Consumption and Scrofula is insisted on; and is supported by a consideration of their intermixture in families, their frequent co-existence in the same individual, their mutual convertibility, and their interchangeability, or power of alternation.

In chapter 6, the author treats of the Relation of Consumption to other Tubercular Diseases; especially tabes mesenterica, hydrocephalus, and chronic peritonitis.

Chapter 7 treats of the Relation of Consumption to Diseases of a Different Character. Dr. Cotton discards the idea of any disease, as ague or rheumatism, being antagonistic to phthisis. *Fistula in ano*, believed by some to be very frequent, "was met with, in 1000 cases, only three times; and although this must be taken with some reserva-

tion—since the majority of the patients were in an early stage of phthisis, while fistula is more likely to be met with at a later period—it still affords sufficient evidence that the common opinion regarding its frequency is incorrect.”—(p. 49.) When it occurs, Dr. Cotton believes it to be sympathetic, and has observed the tubercular disease to be kept in check by it.

Chapter 8 treats of the Predisposing Causes. Under this head the author reviews the influences, real or alleged, of age, sex, stature, constitution, temperament, hereditary transmission, occupation, climate, irregularities of living, intemperance, neglect of personal cleanliness, irregular or insufficient food, inactivity, insufficient clothing, mental influence, dyspepsia, chest-disease, and the form of the chest. We quote a few paragraphs to show his opinions.

“The disease is most frequent between the ages of twenty and thirty—more than 30 per cent.” (of the 1000 cases observed) “having occurred within this period: the next age most favourable to its development is from thirty to forty years; the next to this is from ten to twenty years; and after the age of forty its frequency gradually lessens, until, as we approach the ‘three-score years and ten,’ few cases present themselves.”—(p. 55.)

“It can no longer be doubted that, at least in and around our metropolis, consumption is more frequently to be seen in males than in females.”—(p. 57.)

“I have hitherto failed to observe amongst consumptive patients an excess of what might be called one particular temperament. The colour of the hair and skin—the development of the subcutaneous tissues—the condition of the abdominal organs—the state of the nervous system—all of which are looked on as the indices to temperament, do not appear to me to offer the slightest assistance in the diagnosis of phthisis, nor to bear any necessary relationship to the disease. Consumption does not, as is commonly supposed, show any preference to those whose gentle nature or mental endowments claim a more than usual amount of admiration: it is true that these are too often its victims; but the practical physician finds that the pleasing form and brilliant genius are not oftener its prey than are the unattractive, or the feeble in intellect; and he has to encounter murmuring and discontent, scarcely less frequently than he is called on to admire cheerfulness and resignation.”—(p. 60.)

“The *mechanical* origin of consumption ‘in needle-makers, miners, glass-cutters, etc.’ has been much over-rated, and it may fairly be questioned whether such trades might not be carried on with impunity, if greater respect were paid to sanitary regulations. It is the impure air—the confinement—the unnatural posture—the deficiency of light—together with the mental and physical depression to which they are subjected, which render our labouring classes so prone to phthisis.”—(p. 64.)

In chapter 9, Dr. Cotton speaks of the Exciting Causes. Severe or long-continued predisposition may develop consumption without the supervention of an exciting cause; or one predisposing cause supervening on another, may act the part of an excitant. But certain inflammatory states of the chest, catarrh, influenza, fever, pregnancy, lactation, etc., have more or less exciting influence: and some of these causes are commented on by the author.

With regard to the much-disputed question as to the influence of pregnancy on phthisis, Dr. Cotton believes that in the absence of a phthisical predisposition, pregnancy has no tendency to lead to phthisis. He does not “remember ever having observed a case of phthisis among those who have had large families, except in conjunction with hereditary tendency or other equally evident predisposing cause. But in cases where there is a phthisical liability, hereditary or otherwise, there is much fear of the disease being called into activity by the process of gestation, especially if it should occur either very frequently, or at too early an age.”—(p. 95.) The author is satisfied that, as a general rule, females predisposed to consumption, but not actually consumptive, are more liable than others to become mothers; but, when the disease has commenced, the liability to pregnancy is diminished in proportion to the advance of the malady.

Lactation generally aggravates consumption: and long-continued nursing—especially common among the poorer classes, is most energetic in this, and even in sometimes

giving rise to the disease, not only in persons predisposed to it, but in those who are apparently free from hereditary taint.

II. SYMPTOMS OF CONSUMPTION. In chapter 1, of this part, Dr. Cotton gives a general description of the several stages. He describes (1) the period preceding the formation of pulmonary tubercles; and (2) that subsequent to their development: the latter being divided into three stages: viz.; that of miliary and crude tubercle; of softening; and of expulsion and the formation of cavities.

In chapter 2, we find a more Particular Description of the Prominent Symptoms. Under this head are noticed the phthisical aspect, the pulse, phthisical cough, and its diagnosis from cough from other causes, expectoration, hæmoptysis, dyspnoea, pain, loss of weight, perspiration, diarrhoea, hectic fever, œdema, delirium, meningitis, cerebritis, softening of the brain, bronchitis, pneumonia, pleurisy, pneumo-thorax, low inflammation of the pharynx, dyspepsia, incurvation of the finger nails, and the brick-red or blue streak on the gums.

The physiognomy of phthisis is contrasted with that of malignant disease, anæmia, etc. We exhibit the differences, as stated by Dr. Cotton, in a tabular form.

	Complexion.	Features.	Eye.	Countenance.
Phthisis	Generally sallow or pearly white.	Sharpened.	Bright and intelligent, yet expressive of languor.	Mixed anxiety and animation.
Malignant affections	Peculiar opaque and muddy hue.	Less prominent.	Dull and sunken.	Depressed.
Anæmia	Dead white, rarely sallow.	Rounded, face puffy.	Heavy and inexpressive.	Depressed, but not anxious.
Chronic disease of digestive organs	Pale or yellow.	Sharp.	Languid.	Depressed.

As consumption advances, the aspect changes in degree; but the physiognomy of phthisis is not always plainly marked, and sometimes it seems to indicate a much more advanced state of disease than really exists.

The frequency of the pulse is regarded by Dr. Cotton as most useful in prognosis: increased rapidly being a very unfavourable symptom, while diminution, or non-acceleration in frequency, render the prospect brighter. The phthisical cough, like many other symptoms, must be taken in connection with others to be of value: it is closely resembled in its character by the gastric or stomach cough, the hysterical cough, the catarrhal cough, and the bronchial cough.

Hæmoptysis was observed in 53·6 per cent., or rather more than one-half of the patients: but, making allowance for its occurring subsequently in some cases, and being forgotten or not noticed in others, the author would suppose that “not much less than two-thirds of all consumptive patients become, at one period or another, the subjects of hæmoptysis.”—(p. 123.) It is slightly more frequent in males than in females. With regard to its value in prognosis, Dr. Cotton observes that “the cases in which hæmoptysis occurs usually prove the most favourable, and the most chronic: but this, of course, applies only to those in which the loss of blood is moderate, and the patient able to bear it. When the hæmorrhage is excessive, or when it happens in weak or timid persons, it is usually a very serious, and sometimes even a fatal symptom.”—(pp. 125-6.)

The notices of the other symptoms of phthisis are instructive, and will repay perusal. The absence, however, of any reference to the state of the catamenial functions in phthisis is an omission. One more quotation from this chapter we will make.

“A low inflammatory condition of the pharynx is not an unfrequent attendant upon phthisis, and sometimes appears among its earliest symptoms. It usually commences at its posterior wall, and has a tendency to spread, not only over the whole pharynx, but also into the larynx, laying, in many cases, the foundation of what is termed laryngeal phthisis. The mucous membrane presents, at first, a number of dark or vivid red

patches or streaks, which gradually coalesce; a yellowish tenacious mucus soon appears upon its surface; the tonsils become enlarged, and the uvula is elongated. If the mucous follicles upon and behind the tonsils be now carefully examined, they are often seen to contain a yellowish white substance, apparently of a scrofulous nature, which, becoming expelled, frequently leaves behind it small ulcerations. These ulcerations sometimes spread, and involve a considerable portion of the pharynx, especially at its posterior part. The epiglottis, meanwhile, frequently becomes red and congested: the laryngeal mucous membrane participates in the attack; and the general symptoms of laryngeal inflammation—of which more will be said elsewhere—make their appearance. In many instances, the diseased action remains limited to the pharynx; but in those cases where it extends to the larynx, it sometimes altogether leaves the pharyngeal membrane.”—(pp. 157-8.)

In chapter 3, Dr. Cotton describes the different forms of Consumption: viz.; acute, chronic, (which he subdivides into *florid* and *languid*, depending on the physical condition of the patient) the phthisis of children, and laryngeal phthisis.

Chapter 4 treats of the Physical Signs, which are described according to the stages in which they occur.

III. TREATMENT OF CONSUMPTION. In the first chapter, under the head of Preventive Treatment, the author speaks of the method of guarding against consumption (1) in healthy persons: and (2) in persons predisposed to it, or otherwise unhealthy. We recommend his concise remarks on this subject to the careful attention of our readers. There is much truth in these sentences. “There is no position in life, whether rich or poor, which might not be deprived of one-half its productiveness of disease, by a proper respect to sanitary and moral laws.”—(pp. 189-90.) “Enough, perhaps, has been said, to show how greatly the preservation of health and the avoidance of tuberculous diseases are within our own control; and that even when consumption is actually threatened, much may be done towards keeping it in abeyance, if not actually escaping it.”—(p. 195.)

In chapter 2, Dr. Cotton describes the Treatment of Phthisis before Tubercle is deposited. Under proper diet and medicinal treatment—in which latter steel and cod-liver oil are especially useful—he is perfectly satisfied that this stage will, in many cases, entirely disappear.

In chapter 3, we find some observations on the Treatment of Phthisis after Tubercle has been deposited. Change of air and scene, fresh air and exercise, thorough mental relaxation, the use of nourishing diet, tonics, and local counter-irritation, variously modified according to special circumstances, are considered by the author as the principal remedies. Of the alleged specific action of sea air, he is doubtful. The indications of treatment are pointed out to be—

To restore the health and vigour of the body;

To relieve the different symptoms as they arise; and

To check the further progress of the local or pulmonary disease.

Chapter 4 is devoted to the Treatment of the Various Forms of Consumption; viz.: acute phthisis, and laryngeal phthisis. Dr. Cotton speaks highly of the system of *topical medication* of the larynx, of the safety and usefulness of which he has been convinced by Dr. Horace Green, of New York, the principal advocate of this treatment. In the operation, the tongue must be pressed downwards and drawn forwards, while a sponge is introduced into the larynx, moistened in a solution of from gr. x to 3ss. of crystals of nitrate silver in an ounce of distilled water. But, as this method may cause unpleasant sensations, Dr. Cotton frequently *drops* the solution through the glottis by means of properly constructed forceps with a sponge at the end: and Dr. Theophilus Thompson has invented a small syringe for the same purpose.

In chapter 5, Dr. Cotton gives a more particular description of the Chief Agents employed in the Treatment of Consumption. He enters very fully into the subject of change of air and climate; and brings forward arguments in support of the following statements:

“1. That change of air and scene is one of the most important elements, both in the prevention and treatment of consumption; and in an early stage of the disease, when the strength will permit, may, as a general rule, be sought in the spot most agreeable to the taste of the patient.

“2. That after tubercular softening has commenced, and, for still stronger reasons after cavities have formed, the patient should not leave his native shore.

“3. That it is unnecessary, at any stage of consumption, to seek a foreign residence, as England offers advantages equal to, and in many respects greater than, any other country.”—(p. 241.)

He brings evidence to show, not only that no climate can be considered free from phthisis, but even that Madeira, the South of France, Italy, and other places to which phthisical invalids are commonly sent, not only do not deserve their high reputation, but that some of them even exert an injurious influence. He continues:

“But it would be in vain for me to assert that the health may not be benefited by a winter residence in some of these districts; since numbers who have made the experiment, under proper conditions, are known to have returned with their strength renovated, and their tubercular disease, perhaps, arrested. I would only state, as my firm belief, that the same effect might equally have been gained in these cases, *could the patients have been induced to think so*, by the judicious selection of some place in the southern parts of England. There are some minds so constituted, that the monotony of an English country town, for the whole winter, would be intolerable, whilst the gaiety and novelty of a foreign residence would compensate for nearly every deprivation; and it may be right to indulge the tastes of such patients, if it can be done with safety: but the great mass of invalids, more especially females, may, I am convinced, find themselves, at every season of the year, equally well, and far happier, in their own country.”—(pp. 253-4.)

Some observations on cod-liver oil, other animal and vegetable oils, iodine, tonics, and other remedies, employed in phthisis, terminate the volume: which we with pleasure recommend to the perusal of our readers, as a faithful and succinct record of practical experience and observation.

DE LA CONTAGIONABILITÉ DE LA PHTHISIE PULMONAIRE, FONDÉE PRINCIPALEMENT SUR DES FAITS PRATIQUES. Par J. DE MUYNCK, Docteur en Médecine, etc. pp. 94. Gand: 1852.

(ON THE CONTAGIOUS NATURE OF PULMONARY PHTHISIS, FOUNDED PRINCIPALLY ON PRACTICAL OBSERVATIONS. By J. DE MUYNCK, M.D. Ghent: 1852.)

Dr. DE MUYNCK cites many of the older authors, who have given evidence in favour of the contagious nature of consumption; and further seeks to establish his views by reasoning on the observed phenomena of the disease. The following brief extract contains, we think, the pith of what he intends to convey.

“The facts which I have pointed out, and the reflections which naturally flow therefrom, justify the following conclusions:—

“1. All cases of phthisis resulting from specifically vitiated organisation—those, in fact, which arise from a peculiar virus, or a profound and continued change in a system of organs, are contagious and hereditary.

2. All those cases, on the contrary, which are accidental, or produced by a local cause, and which are not accompanied by a diathesis, cannot be communicated in either of these ways.”—(p. 73.)

Dr. Cotton, in his work on phthisis reviewed above, refers the cases of alleged communication of phthisis by contagion to mental impressions, principally of fear. The influence of the mind must always be remembered in attempting to decide the question of contagion.

We recommend Dr. De Muynck's work to the perusal of those who may be interested in the investigation of the subject on which it treats.

ESSAY ON THE ACTION OF MEDICINES IN THE SYSTEM; or, "On the Mode in which Therapeutic Agents introduced into the Stomach produce their peculiar Effects on the Animal Economy". Being the Prize Essay to which the Medical Society of London awarded the Fothergillian Gold Medal for 1852. By FREDERICK WILLIAM HEADLAND, B.A., M.R.C.S., etc. 8vo., pp. 346. London: 1852.

THE subjects discussed in this Essay lie at the foundation of rational therapeutics, and yet there is too much of truth in the observation of Mr. HEADLAND, that "on no question, perhaps, have scientific men differed more than on the theory of the action of medicines." With a view to provide a remedy in some degree adapted to the removal of this reproach, the author of this elaborate essay has presented us with an arrangement, which certainly has the merit of clearness and perspicuity. The language employed is plain and simple, and can scarcely fail of being understood; while the copiousness and variety of the materials give evidence of diligent and judicious gleanings. The work is on a level with the science of the day, and indicates a philosophic tone of thought equal to the logical disposition of the propositions which it brings before the reader.

After some introductory remarks, and a short review of what has already been written on the subject, Mr. Headland embodies his own views in ten leading propositions, which form the bulk of the book: he concludes with some interesting observations on the action of a few of the more important medicines. We shall give the reader the propositions in detail, with a few remarks as we proceed; then the classification founded upon them; and lastly, we shall notice a few of the author's observations on the action of particular drugs.

Proposition 1. That the great majority of medicines must obtain entry into the blood or internal fluids of the body, before their action can be manifested.

This is attempted to be demonstrated by four considerations: 1. That a medicine introduced into the system elsewhere, acts in the same way as when introduced into the stomach. 2. That continuity of nerve is not necessary for the propagation of such effects; but vascular connexion is necessary. 3. The circulation of the blood is sufficiently quick to account even for the operation of those poisons which act most rapidly by influencing the nerve-centres. 4. The great majority of medicines have been detected in the blood, and found in the secretions formed from it.

These arguments are founded on well-known facts, and on special experiments conducted by M. Magendie, Sir B. Brodie, and M. Ehbort, on the Woorara poison; on various experiments by Dr. Blake, M. Volkmann, Hering, Mr. Allen, M. Runge, M. Ragsky, Drs. G. Bird, Tiedemann, Gmelin, Wöhler, and Garrod; and from them the author concludes, that, before the proper and peculiar and specific action of a medicine can be manifested, it must pass into the blood. He does not deny, however, that some effect may be produced by the introduction of certain medicines into the stomach, before their absorption, and by virtue of the nervous irritation which they excite; and this effect, he allows, may even be fatal.

Prop. 2. That the great majority of medicines are capable of solution in the gastric or intestinal secretions, and pass without material change, by a process of absorption, through the coats of the stomach and intestines, to enter the capillaries of the portal system of veins.

This is illustrated by an inquiry into the nature and function of the gastric and intestinal secretions; the laws of endosmotic absorption, and their fulfilment in this case; and the mode by which the great majority of medicines are reduced to a state of solution, which is necessary before they can be absorbed. The author rejects the endosmotic theory of the action of saline purgatives, first proposed by M. Pousseuille, and afterwards adopted by Liebig, Pereira, Golding Bird, and others, and with it the practical inferences which the two latter writers have drawn from it.

Prop. 3. That those medicines which are completely in-

soluble in water, and in the gastric and intestinal juices, cannot gain entrance into the circulation.

To establish the proof of this proposition, the author introduces some experiments of his own, with a view of disproving the possibility of the absorption of insoluble substances. These experiments must, however, be repeated in various ways, before the results can be considered satisfactory. Negative evidence is at best imperfect and fallacious, and avails little when positive facts appear to be opposed to it.

Prop. 4. That some few remedial agents act locally on the mucous surface, either before absorption, or without being absorbed at all; that they are chiefly as follows:—A. Irritant Emetics; B. Stomach Anæsthetics; C. Irritant Cathartics.

It will be perceived, that the foregoing propositions relate to the action of medicines after their introduction into the stomach, and before their passage into the blood. The two next propositions concern the action of medicines after their passage into the blood.

Prop. 5. That the medicine, when in the blood, must permeate the mass of the circulation, so far as may be required to reach the parts on which it tends to act. There may be two possible exceptions to this rule: A. The production of sensation or pain at a distant point; B. The production of muscular contraction at a distant point.

Prop. 6. That, while in the blood, the medicine may undergo change, which in some cases may, in others may not, affect its influence. That these changes may be: A. Of combination; B. Of reconstruction; C. Of decomposition.

The remaining four propositions contain a classification of medicines, in which they are divided (according to the author's views of their mode of operation) into hæmatics, or blood-medicines; neurotics, or nerve-medicines; astringents; and eliminatives.

Prop. 7. That a first class of medicines, called *hæmatics*, act while in the blood, which they influence. That their action is permanent. That of these, some, called *restoratives*, act by supplying, or causing to be supplied, a material wanting, and may remain in the blood. That others, called *catalytics*, act so as to counteract a morbid material or process, and must pass out of the body.

Prop. 8. That a second class of medicines, called *neurotics*, act by passing from the blood to the nerves, or nerve-centres, which they influence. That of these, some, called *stimulants*, act so as to exalt nervous force, in general or in particular. That others, called *narcotics*, act so as first to exalt nervous force, and then to depress it; and have also a special influence on the intellectual part of the brain. That others, again, called *sedatives*, act so as to depress nervous force in general or in particular.

Prop. 9. That a third class of medicines, called *astringents*, act by passing from the blood to muscular fibre, which they excite to contraction.

Prop. 10. That a fourth class of medicines, called *eliminatives*, act by passing out of the blood through the glands, which they excite to the performance of their functions.

These four classes of medicines Mr. Headland proposes to subdivide as follows:

CLASS I. HÆMATICA.

DIV. I. RESTAURANTIA.

Ordo 1. Alimentaria.

- " 2. Acida.
- " 3. Alkalina.
- " 4. Tonica.
- " 5. Chalybeata.
- " 6. Solventia.

DIV. II. CATALYTICA.

Ordo 1. Antiphlogistica.

- " 2. Antisyphilitica.
- " 3. Antiscrophulosa.
- " 4. Antiarthritica.
- " 5. Antiscorbutica.
- " 6. Antiperiodica.
- " 7. Anticonvulsiva.
- " 8. Antisquamosa.

CLASS II. NEUROTICA.

DIV. I. STIMULANTIA.

- Ordo 1. Stimulantia Generalia.
- " 2. Stimulantia Specifica.

DIV. II. NARCOTICA.

- Ordo 1. Inebriantia.
- " 2. Somnifera.
- " 3. Deliriantia.

DIV. III. SEDANTIA.

- Ordo 1. Sedantia Generalia.
- " 2. Sedantia Specifica.

CLASS III. ASTRINGENTIA.

- Ordo 1. Astringentia Mineralia.
- " 2. Astringentia Vegetabilia.

CLASS IV. ELIMINANTIA.

- Ordo 1. Sialogoga.
- " 2. Expectorantia.
- " 3. Cathartica.
- " 4. Cholagoga.
- " 5. Diaphoretica.
- " 6. Diuretica.

That this classification has its imperfections, cannot be doubted; and indeed the very nature of the subject prevents the possibility of a wholly unobjectionable division being made. We are, nevertheless, much indebted to the author for a framework, adapted to the present aspect of therapeutics, calculated to guide observers, and to facilitate the study of the action of medicines.

The last chapter of the work is in some degree explanatory of the table, as it shows that some medicines may be numbered under distinct heads, having a distinct action in different stages of their progress through the system. Thus, mercury, as an antiphlogistic, belongs to the class i., div. ii., ord. i.; as an antisymphilitic, to class i., div. ii., ord. ii.; as a cathartic, to class iv., ord. iii.; as a cholagogue, to class iv., ord. iv. This view is at once philosophical, simple, and practical. The medicines which are considered worthy of special notice in this chapter, are, cod-liver oil, sulphuric acid, potash, quinine, iron, antimony, mercury, iodine, colchicum, arsenic, ammonia, strychnia, chloroform, opium, hydrocyanic acid, aconite, digitalis, and tannic acid. Although we cannot agree with everything the author advances, yet, as a whole, his review of the action of these important agents is one of the most interesting parts of the work: it will tend in some degree to explain and harmonize the conflicting views, concerning the temper of familiar medicines. The following remarks on calomel illustrate this tendency:

"Some have, without sufficient reason, assumed calomel to be a sedative when given in large doses. To act in this way, very large doses have been recommended and given in fever and malignant cholera. Calomel is naturally an insoluble substance, and in these cases the function of absorption is at the very lowest ebb; so that it is probable that the large doses are often left unabsorbed, and pass out of the bowels very much as they entered, producing scarcely any more effect than so much chalk." (P. 316.)

We are somewhat disappointed in the account given of the action of iodine. The author faithfully details the contradictory opinions of different writers, but offers no opinion of his own; nor does he attempt to reconcile these differences. If all that is said of iodine be true, large doses are dangerous, and small ones are useless. Some practitioners have known it to cause absorption of the mammae and testes; but M. Magendie states, that he has never known such a thing to occur. By many it is believed to cause emaciation; but the last-mentioned author has observed, that strumous patients frequently become fattened through its employment. "The therapeutic actions of iodine have been ascribed by Dr. Billing to a contraction of the capillary vessels; by Dr. Pereira, to a liquefaction of the blood; by others, to a direct stimulation of the absorbent system." The consequence of this discrepancy is, that iodide of potassium is prescribed by different practitioners in doses varying from two or three grains to as many drachms, for all sorts of diseases.

Mr. Headland's book is a text-book of the action of medicines. It is a well timed publication; for now it is too much the fashion, even in the profession, to undervalue drugs; and there cannot be a question that the really important articles of the *materia medica* will rise in esteem, just in proportion as we become enlightened as to their mode of action in the human economy.

We conclude with an extract from the introductory remarks of the author:

"There have been, more or less, in all ages, two systems or schools of medical treatment, of which the one prevails among ignorant men, and in rude states of society, but the other requires a higher degree of enlightenment. These are the empirical and the rational systems. The first is founded on simple induction. By accident or by experience it is found that a certain medicine is of use in the treatment of a certain disorder; it is henceforth administered in that disorder; and on a number of such separate data an empirical system is constructed. It naturally requires for its elaboration a comparatively small degree of knowledge.

"Now, this observation of facts is indispensable as a beginning, but something more is required. We must not be satisfied with taking them separately, but we must proceed to compare together a large number of facts, and draw inferences from this comparison. And our plan of treatment will become rational, when, on the one hand, from an accurate knowledge of the symptoms of diseases, we are better enabled to meet each by its appropriate remedy; and, on the other hand, when, from some acquaintance with the general action of a medicine, we are fitted to wield it with more skill and effect, and to apply it even in cases where it has not yet been proved beneficial. Thus, for the proper perfection of medicine as a rational science, two things are in the main needed; the first is, a right understanding of the causes and symptoms of disease; the second, a correct knowledge of the action of medicines. Should our acquaintance with these two subjects be complete, we should then be able to do all that men could by any possibility effect, in the alleviation of human suffering. This sublime problem is already being unravelled at one end. Diagnosis and nosology are making rapid strides; and perhaps we shall soon know what we have to cure. But at the other end our medical system is in a less satisfactory condition; and though some impatient men have essayed, as it were, to cut the Gordian knot, and have declared boldly on subjects of which they are ignorant, yet it must be confessed, that in the understanding of the action of medicines, and of their agency in the cure of diseases, we do not much excel our ancestors. While other sciences are moving, and other inquiries progressing fast, this subject, so momentous in its applications, has, in spite of the earnest labours of a few talented investigators, made, after all, but small progress. Let but those who feel this want bestir themselves to remove it, and it will soon be done. Those doubts and difficulties, which are now slowly clearing away before the efforts of a few, will then be finally dispelled by the united energies of all; and instead of our present indecision and uncertainty on many points, we shall find ourselves eminently qualified to wage the conflict with disease, being skilled in that science whose name bespeaks its peculiar importance, the science of *Therapeutics*." (P. 3.)

WHAT TO OBSERVE IN MEDICINE; or the Means of Improving it, as a Science and an Art: with the duties of the Medical Profession to their Patients, the Public, and themselves. An Introductory address to the Harveian Medical Society, delivered at the commencement of its Twenty-Second Session, Oct. 7th, 1852. By JAMES BIRD, M.D., F.R.C.S.Eng. 8vo., pp. 25. London: 1852.

DR. BIRD's address breathes an excellent spirit; and is well calculated to excite to scientific inquiry, and brotherly harmony in the profession.

Combination for scientific investigation is strongly insisted on by Dr. Bird as the only means of attaining great results. This opinion we hope to see gaining ground every day within our Association, so that it may soon do more than it has yet achieved in the way of collecting, classifying, and generalizing the results of individual experience.

Dr. Bird, after giving a brief outline of the intricacies and requirements of medicine, pursued both as a science

and as an art, thus refers to the value of medical association in pursuing medical inquiries :—

"To unravel one and supply the other, must be the business of a lifetime; not of one, but of many individuals in succession; who, selecting a well-digested plan of experimental medicine, for collecting facts on which to found general principles and rules of art, must labour, with a sincerity of purpose, to obtain common grounds for comparing them in all countries; rejecting those that are doubtful, and perfecting all those that are incomplete or carelessly observed. In the absence of any association, or scientific centre of common intercourse, where the united efforts of the enlightened medical men of Europe and of England might be made tributary to this great object of our profession, we should like to see all the scientific medical societies of this kingdom and of Europe organized into an association, for carrying out this most legitimate and important inquiry. Looking at other scientific departments, and contemplating what great and noble things have been accomplished by the union of wealth and enterprise, I do not despair of yet seeing the establishment of such an union of zealous medical investigators of the truth, before the burning light of whose labour the glare of false systems will be extinguished."

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

THERAPEUTIC USES OF THE BARK, LEAVES, SEEDS, AND ROOT OF THE COMMON ASH (FRAXINUS EXCELSIOR).

In a work recently published by Dr. OTTERBOURG,* some interesting remarks are made upon the use of the *leaves* of the ash in gout and rheumatism. It appears, that since these leaves were introduced into the *materia medica* of Germany in 1841, by Rademacher, they have enjoyed a very considerable reputation for remedial powers in the diseases just named. Apparently in ignorance of the therapeutic reputation which ash leaves had obtained in Germany, two French physicians, Drs. POUGET and PEYRAUD, published a paper in the *Union Médicale* for Nov. 27th, 1852, in which they detail various cases of gout and rheumatism cured by the ash leaves; and among the cases of gout described is that of one of the authors, Dr. Peyraud. The value of the *bark* of the ash is of older date, and is better known. A few remarks, founded upon the works referred to, and upon information gleaned from other sources, may be useful to many of our readers, who, in hospital, dispensary, or union practice, may be often glad to be able to substitute cheap and indigenous remedies for costly drugs, whenever equal advantages can be obtained from the former.

THE BARK of the *fraxinus excelsior* is bitter and astringent. Its febrifuge action is undoubted; and so long ago as 1712 it received the name of European cinchona. It has been employed in the form of tincture, decoction, infusion, and powder. The dose is rather larger than of the corresponding preparations of cinchona. The infusion is as good a form as can be adopted. We may remark, that the retail price of the bark in Covent Garden Market is two-pence per ounce.

THE LEAVES are said by some to be purgative; by others they are declared to have no such effect. From their general similarity of appearance, they are sometimes substituted by the druggist for senna leaves. The London seed-vendors generally have a supply of ash leaves, but they inform us that they are seldom asked for, and that they do not know the therapeutic virtues on account of which their customers purchase them. We believe that an investigation of the medicinal properties of ash leaves would, if properly conducted, yield some useful results; for, in various parts of this and other countries, they now are and long have been used successfully in various traditional nostrums.

In 1842, Dr. Peyraud had his first attack of gout, which was severe, and lasted for twenty-five days. During the three following years, the attacks increased in frequency and severity. Having derived little benefit from the remedial means which he had resorted to, he listened to the suggestion of one of his patients, an inhabitant of the department of Dordogne in France, who advised him to try an infusion of ash leaves, informing him,

at the same time, that his forefathers had been cured by this prescription, and that many of the country people got rid of "their pains" by employing it. Dr. Peyraud took the infusion of ash leaves, and from 1845 to 1849 had no fit of gout. He then had an attack, which yielded in five days to the infusion of ash leaves, used under the observation of Dr. Pouget. These circumstances recalled to the recollection of Dr. Pouget a fact which he might otherwise never again have considered. It was this,—that when he was a physician at Sorèze, in 1824, the peasants of that place had spoken to him of the great power which an infusion of ash leaves had in driving away pains. He afterwards discovered that it had been used forty years ago as a gout specific by the peasants of Auvergne.

A commercial traveller, who had been gouty for twenty years, and had saturated himself with the syrup of Boubée and other vaunted specifics, consulted Dr. Pouget. At this time, he was an almost constant prisoner in his room with successive attacks. After eleven days use of the infusion, he was able to walk two *kilomètres* (one and a quarter English mile); in fifteen days he resumed his journeys, and was able to travel without suffering, by diligence, from Bourdeaux to Quimper.

Several other cases are detailed, some of them acute, and others chronic. Articular rheumatism, in numerous instances, was also benefited by the infusion of ash leaves.

Drs. Pouget and Peyraud thus sum up their opinions as to its efficacy and mode of administration:

"The powder (infused) of ash leaves is perhaps a true specific for gout and rheumatism, combining with the most powerful curative action, the immense advantage of giving rise to no dangers nor inconveniences, such as result from the use of colchicum. Having no purgative properties, it may be taken in any condition of the digestive canal. It causes neither nausea, sickness, general discomfort, nor depression. Experience enables us to state, that generally, under its use, at the end of four or five days, and sometimes sooner, the pain, redness, and swelling have sensibly diminished in intensity, or have even disappeared."

The method of administration is thus minutely described.

1. Each dose of the powdered leaves ought to be infused for three hours in boiling water.
 2. Before this infusion is taken, it requires to be sweetened to taste, and strained through a linen cloth.
 3. In acute gout, and especially at the commencement of the attack (whether with or without fever), two doses of the powder ought to be infused in three cups of water; one to be taken at bed-time; the second, early in the morning; and the third, between breakfast and dinner. The medicine, in diminished doses, requires to be continued for eight days after the symptoms have disappeared.
 4. In chronic gout, a cup of infusion ought to be taken night and morning, for a long period. Fits of gout may be more or less indefinitely postponed by having recourse to this treatment, say for eight or ten days in every month.
 5. In acute rheumatism, the infusion greatly assists the action of other medicines which are commonly used; and it is particularly beneficial in removing articular swellings. It produces equally good results in chronic rheumatism, whether articular, muscular, or nervous.
 6. During the use of the remedy, it is not necessary in any way to change the mode of living, nor to adopt any special regimen, so long as the laws of sound hygienics are observed.
- Speaking of the dose and method of administration, Dr. Otterbourg says: "Several times during the day, thirty-two grammes of ash leaves may be taken, infused in a sufficient quantity of hot water. In muscular pains, and in rheumatism of the scalp, this is an excellent means of cure."

From various works we have gleaned the following notes regarding the bark, leaves, seeds, and root.

PLINY ascribes numerous medicinal virtues to ash leaves, and speaks of them as a specific for the bites of serpents. (Lib. vii, c. 13.) BOUREGARD, a surgeon of Rochelle (*Anc. Journ. de Méd.*, vi, 233), and others, have cited cases from their own practice in corroboration of this statement. WILICH and others speak of the tonic properties of ash leaves. PÉLÉTIN and GILBERT recommend them in scrofula. TABLET, in 1711, declared them to be equally purgative as senna leaves, but less liable to cause griping. COSTE and WILLEMOT found them less aperient than senna leaves, one-third more being required as a dose. They state, that the evacuations were sooner completed, and that, along with their purgative properties, they have a diuretic action. HOOPER, in his *Medical Dictionary*, has the following notice: "The bark, when fresh, has a moderately strong bitterish taste. It possesses resolvent and diuretic qualities, and has been successfully administered in the cure of intermittents. The seeds

* *Aperçu Historique sur la Médecine Contemporaine de l'Allemagne. Paris: 1852.*

are occasionally exhibited as diuretics, in the dose of a drachm." The vermifuge action of the bark is mentioned by several authors, and BERGIIUS says, "Sunt qui multum sperant de cortice fraxini, in lacte vel aqua cocto, adversus vermes, atque etiam contendunt, hunc corticem sæpe vermes pepulisse, ubi alia fellunt." (*Tomus* ii, p. 832. *Stockholmia*: 1778.) According to Martin-Solon, the decoction of the root is purgative and emetic. (*Bul. Gén. de Thérap.* i, 163.) MÉRAT and DE LENS, in the *Dict. de Matière Médicale*, give the fullest notice which we have seen of the medicinal properties of the different parts of the ash. At the end of their article, the following authorities are cited: Schroer (J. C.) *Description du Frêne avec l'Énumération de ses Propriétés Médicales* (en Allemand), etc. Francfort-sur-l'Oder: 1700, in 8. Helvig (G.) *Diss. de Quinquina Europæorum, sive Cortice Fraxini*. Grypswaldia: 1712, in 4. Schreger (B. N. G.) *Diss. de Corticis Fraxini Excelsioris Naturæ et Viribus Medicis*. Lipsiæ: 1794, in 4. There is no reference to *fraxinus excelsior* in Woodville's *Medical Botany*; and Decandolle, Richard, Stephenson, Churchill, Duncan, and Pereira, make no mention of its medicinal properties.

Additional information is obviously required regarding the medicinal properties of the bark and leaves of the common ash. Can any of our readers contribute towards supplying this deficiency? Under certain circumstances, the leaves, it appears, are purgative, and in others astringent: this, and various points connected with the physiological effects produced on different organs, evidently demand experimental elucidation. The discrepancy of opinion among observers may be explained by the experiments having been made with leaves gathered at different seasons. MÉRAT (*Dict. de Mat. Méd.*) advises that the leaves be gathered when in full vigour, and carefully dried for winter use; but in summer they may be used green.

DANGEROUS SALIVATION FROM THE ECTROTIC TREATMENT OF SMALL-POX BY MERCURIAL OINTMENT.

DR. GEORGE PATERSON, of Tiverton, has published in the *Monthly Journal of Medical Science* for Dec., 1852, a case of this description, lately treated by himself and Mr. Mackenzie, of the same town. He remarks, that, although this method of treatment has been much lauded both at home and abroad, no case of its producing salivation has till now been placed on record. Mercurial ointment thickened with starch, as recommended by Dr. Hughes Bennett,* was for several successive days smeared over the face, and allowed to remain in contact with the skin. The quantity employed amounted to not more than one ounce and a half. A week after its use had been discontinued, mercurial salivation, ulceration of the gums, etc., showed themselves; and they seem to be correctly referred by Dr. Paterson to the use of the ointment, and not to the consequences of the disease for which the patient was under treatment. The concluding paragraph of Dr. Paterson's communication is as follows:

"There are circumstances in which it becomes a duty to relate the opprobria, not less than the successes of our practice; and the present appears to me to be a case of the sort. It reveals a risk from a particular mode of treatment, pursued in strict conformity to the instructions of those in whose hands it has proved successful, the possibility of which every one would of course admit, but which appears to have been treated of, even by authorities opposed to the practice, as scarcely worthy of being taken into their account. I am far from wishing to say, that a new practice is to be judged and condemned by the untoward accidents of a single case; but I cannot help looking upon mercurial salivation as so great an evil, when superadded to the already existing local irritation and swelling of the face and mucous membrane, which usually occur in severe cases of small-pox, that the risk of its occurring in even a single instance may well affect the general question of its safety and expediency; and that more especially, when we find the drug, as in this case, accumulating and lying latent in the system, and its specific effects manifesting themselves suddenly and with unusual severity some days after its use had been given up, and after all cause of apprehension on the patient's account, either from this source or the original disease, seemed to be at an end."

* Reports of M. Briquet's having used this preparation successfully in the hospitals of Paris, induced Dr. Bennett to try it in two cases in the Royal Infirmary of Edinburgh, according to the subjoined formula:—R. Ung. hydragryi ʒi; Pulv. amyl. ʒij. M. To be smeared over the face night and morning. Dr. Bennett's remarks on the ectrotic treatment of small-pox will be found in the *Monthly Journal of Medical Science* for January 1850, p. 60.

CALOMEL AND SODA COMBINED AS A CATHARTIC.

DR. HUNT states in the *Boston Journal* (vol. xlv., p. 161), that the purgative power of calomel is remarkably increased by the addition of bicarbonate of soda. He says, that two grains of calomel, combined with from ten to twenty grains of soda, purges efficiently without griping. When the bowels and liver have been well acted on, the combination loses its purgative power, and ought to be discontinued. Dr. Hunt believes that bicarbonate of soda has some power in preventing calomel from acting on the gums.

CHLOROFORM IN COLIC, PARTICULARLY IN LEAD COLIC.

DR. ARAN, of Paris, warmly recommends the internal administration of chloroform in repeated doses of from ten to twenty drops, in colic, and particularly in lead colic. He says, that it relieves the spasm more effectually than opium or belladonna, and moreover possesses the great advantage of being more safely repeated than either of these medicines. A hundred and fifty drops may, according to Aran, be given in twenty-four hours; and we have no doubt that even a larger quantity, though seldom required, may be safely administered, as chloroform is very quickly eliminated from the system. In corroboration of the value of chloroform in colic, the writer of these lines adds his experience of its efficacy in his own case. He had suffered the most excruciating pain in the back and abdomen for twenty-two hours, accompanied by incessant vomiting, which opium and hydrocyanic acid failed to mitigate: indeed, they were rejected as soon as taken. A dose of twenty drops of chloroform was then taken, well mixed in a little water. After this, there was no more sickness, and almost instantaneously the pain began to abate, and in ten minutes had entirely subsided. Upon a return of the pain, some hours afterwards, it was again and finally removed by a smaller dose of chloroform. The necessary purgatives were afterwards easily retained, and the cure completed.

PAGLIARI'S HEMOSTATIC.

This nostrum has recently excited a great deal of attention both in France and Italy; and from the reports of Sédillot and others, we are inclined to think that it may really be possessed of considerable power in staunching blood from small or retracted vessels to which the ligature cannot be applied. When the hemostatic is added to blood in a glass vessel, a dense blackish mass is formed.

For some time, Pagliari concealed the composition of his nostrum; but he has now published the following as the formula according to which it is prepared: Take eight ounces of tincture of benzoin, one pound of alum, and ten pounds of water; boil them together, and stir the compound for six hours in a glazed earthen vessel, adding water so as to supply the loss by vaporization, and to allow ebullition to continue. Afterwards, filter the fluid, and preserve it in stoppered bottles. Its taste is styptic, its odour aromatic, and its appearance like limpid champagne.

ACTION OF SULPHURIC ACID.

In the *Archiv. f. Phys. Heilk.* for 1851, Dr. MIQUEL states, that when a *gramme* (15½ grains) of sulphuric acid is administered daily, in a very diluted form, it produces a decided increase in the soluble salts of the urine. From this observation, he infers, that the mineral acids diminish the proportion of the saline ingredients of the blood.

MICROSCOPICAL DISCOVERY.

THE PACCHIONIAN BODIES.

Self-evident though the axiom be, that makes the study of morbid anatomy dependent upon a correct knowledge of healthy parts, the instances are not infrequent in which pathological errors have been committed from mistaking a natural for an abnormal structure. Perhaps the so-called glands of Pacchioni have given rise to one of the most glaring instances of such error: first described by the above named anatomist in 1705, their structure, and their relations to disease of the membranes of the brain have usually been much misunderstood; and physiological conditions having been erroneously supposed to be morbid, the natural consequence is, that what is really the result of disease has been overlooked. Professor LUSCHKA (*Müller's Archiv.* 1852, p. 101) has recently studied the Pacchionian bodies, and the following is a summary of his results.

The bodies in question, which are found closely connected

both with the cerebral and the parietal arachnoid along the course of the longitudinal sinus; held by Soemmering to be granules of fat, and by Rokitsky and Hyrtl to be the products of inflammatory effusion,—are in reality normal, as might *a priori* be supposed from their being found in all persons of all ages, although they may readily be confounded with actual inflammatory exudation under or upon the free surface of the membrane.

The Pacchionian bodies are found *only* near the mesial line, and are unconnected with disease of the subjacent pia mater, which is not found to adhere more closely in their vicinity than elsewhere to the arachnoid, from which latter membrane the granules in question cannot be torn, and of which they are indeed regularly-formed offsets.

Pacchionian Bodies of the Cerebral Surface. On tearing off portions of the arachnoid from the mesial edge of the cerebral hemispheres, it separates easily from the pia mater, and carries with it the Pacchionian bodies, which appear under the lens as shaggy projections of its proper substance, of various form and size, as well as of very different number in different heads. They are usually smaller and less distinct the younger the individual, their size varying from that of a poppy seed to that of a millet seed. Their colour is grey or whitish, and their structure usually firm and fibrous; they are covered with a scanty epithelium, and contain no vessels. The curious cactus-like forms of these bodies are seen in figs. 1, 2.

Figs. 1, 2. Pacchionian bodies, after Luschka; 30 diameters.

Pacchionian Bodies of the Parietal Surface. The fibrous web of the dura mater, where it forms the longitudinal sinus, presents many irregular interstices over which the arachnoid is stretched, and into which it partly sinks. From these points, where the serous membrane is unsupported by the fibrous tissue, spring the Pacchionian bodies, presenting, as on the surface of the hemispheres, various shapes; pressing backwards through the dividing fibres of the dura mater upon the skull, and even into the canal of the sinus, and projecting forwards upon the surface of the brain, so as to come in contact with the Pacchionian bodies already described as springing from the cerebral arachnoid.

In the young they are usually less prominent, and of

Fig. 3. Pacchionian bodies, after Luschka; 30 diameters.

simple shape; but in some cases, especially in subjects more advanced in life, they assume very complex and often regularly beautiful forms, (fig. 3,) and in this case they interlace so closely with those springing from the cerebral arachnoid, that on removing the dura mater, both folds of serous membrane come away together, an occurrence often erroneously attributed to pathological adhesions.

Morbid Conditions of the Pacchionian Bodies. The most remarkable of these is hypertrophy, observed chiefly in old persons; in consequence of which, masses of considerable size are formed, and, pressing into the longitudinal sinuses, sometimes seriously impede the current of the blood. At other times small tumours are produced, which are often mistaken for fungus of the dura mater, and which we ourselves have once or twice noticed as the apparent cause of sudden death by their pressure on the surface of the brain, a pressure the force of which was manifested by their having formed deep pits in the skull above, all but penetrating its substance.

The Use of the Pacchionian Bodies is unknown. It can only be guessed that they may in some way protect or strengthen the veins, as these enter the longitudinal sinus, in man, the only animal in whose head the bodies in question have been detected.

MUSCULAR STRUCTURE OF THE IRIS.

Many opinions, as our readers must be well aware, have been held with regard to the motions of this remarkable structure, some attributing them to vascular erection, others to muscular contraction; and though physiologists are now, we believe, pretty well agreed that the latter is the true explanation, it is interesting to have further anatomical proof of the fact. Mr. J. LISTEN, having had an opportunity of examining a portion of healthy and perfectly fresh human iris, removed in forming an artificial pupil, has succeeded in detecting those elongated "fibre-cells" which are characteristic of unstriated muscle. Prosecuting his researches upon the eyes of various animals, he has displayed the sphincter muscle in the form of a distinct circular belt of fibres, lying upon the posterior face of the iris. In the human subject, it is about one-thirtieth of an inch broad, is thickest at its outer part, and thins off towards the pupil, the margin of which it forms as a sharp edge, covered upon its anterior surface only by some vessels ramifying in delicate membranous tissue. The action of this annular muscle is of course to contract the pupil.

The dilating fibres of the iris cannot be made out so distinctly, and must be carefully distinguished from the blood vessels and nerves of the organ. They appear, however, to pass from its whole circumference towards the outer edge of the sphincter muscle, with which they become blended, and in which they are lost. They are straight throughout the greater part of their courses, but interarch anteriorly with one another, and with the circular fibres, the most external of which are thus rendered less parallel to one another than those forming the pupillary border.—*Journal of Microscopical Science*, No. 1, 1852, p. 8.

PHYSIOLOGY OF THE NERVES.

It is in all probability chiefly by a closer study of the central and peripheral terminations of the nervous tubules that our acquaintance with their physiology is to be extended. The ganglionic centres, on the one hand, in which they take their rise, and which no doubt are the sources of their peculiar power; and, on the other, the wonderfully constructed organs in which they terminate,—(or *vice versa*, according as we speak of motor or of sensitive nerves;)—must, when thoroughly understood, reveal to us more of the hidden properties of nervous structure than can ever be gathered from the study of the mere connecting cords, however complex their arrangement, or however remarkable their course.

Dr. A. WALLER has published (*Müller's Archiv*. 1852, p. 592,) some interesting experiments on the results of dividing the roots of the spinal nerves in various animals, particularly in dogs and pigeons. He found in the first place, that after cutting any nerve across in a living animal, the fibres below the point of division gradually lost their structure, and wasted away or were disintegrated; a result only the same as that often observed on a comparatively great scale in the case of the optic nerve of a blind eye. He found also, that when reunion of the divided ends took place, it was followed by a gradual reproduction of the tubules throughout the whole course of the nerve.

Now, if a ganglion of grey matter intervene between the

point of section and the periphery, this wasting of the tubules *does not take place*, showing that these ganglia are indeed centres of nervous power and nutrition. Thus when both roots of a spinal nerve were divided, both of course wasted down to the ganglion; but *below* the ganglion the fibres belonging to the *anterior* root alone wasted, while those belonging to the *posterior* root, reinforced by new fibres arising from the ganglionic grey matter, retained their integrity of structure, though of course the connexion of the sensitive peripheral parts with the cerebro-spinal axis was suspended till union of the cut ends took place. If the *posterior root alone* was divided, the motor root being left entire, no wasting whatever could be observed in the mixed nerve, all its tubules retaining their structure, and of course the motor powers of the limb remaining perfect. On examining the ganglia in the last case, three or four months after the section, Dr. Waller succeeded in making out the difference between the wasted and disorganized tubules belonging to the posterior spinal root, and those others, perfect and uninjured, which, originating amid the ganglionic matter, were passing down into the mixed nerve.

STRUCTURE OF THE SENSITIVE PAPILLÆ OF THE SKIN.

Our knowledge of the way in which the nerves of sensation terminate in their respective organs is as yet very inexact, and the structure of these organs themselves has been in many respects but imperfectly made out. All acknowledge in the ear, and in the eye, a curious and complicated apparatus suited to receive the impressions of the special object of each of these senses; but in respect of the other three senses, such a relation is less perfectly understood. The researches of Todd and Bowman on the tongue, have however done much to advance our knowledge of the organ of taste; and RUDOLPH WAGNER, (in Müller's *Archiv.* 1852, p. 403,) has given interesting drawings and descriptions of certain peculiar bodies, called by him *corpuscula tactus*, in the tactile papillæ of the skin.

Fig. 4 represents one of these papillæ of the usual well-known form, from the anterior surface of the end of the little finger. It is represented as denuded of its epidermis, the surface of the papilla presenting slight inequalities where the lower layer of epidermic cells had rested, and its substance containing some nucleated fibres. Two nervous tubules are seen rising into it, and terminating in the oval "*Tacthörperchen*" which forms the apex of the papilla, and is embedded in its substance.

Fig. 4. Papilla and Corpusculum Tactus, after Wagner. 400 diameters.

This body has not been isolated, and having been studied only in sections such as those we have copied from Wagner's plate, its intimate structure is not exactly known. Kölliker maintains, that it is composed of a central axis wrapped round with elastic fibres, and distinct dark striæ are certainly observed to cross it in various directions, while small corpuscles are not unfrequent among them. Wagner is quite satisfied, that the nervous tubules actually enter this *corpusculum tactus*, though the exact mode in which they terminate is undiscovered; he has not been able to find any looping of the nerves, though there are other papillæ in which looping *vessels* are easily seen. (Fig. 5.) It is very remarkable, that capillaries and nerves do not appear to coexist in the same papilla, so that those which contain a looping vessel are destitute of a *corpusculum tactus*, and *vice versa*. This appears to us so extraordinary, as to require confirmation; but, if Wagner's account of the structure of the organ of touch prove to be accurate, an interesting addi-

tion will have been made to the physiology of the senses, even although the mode in which these rounded bodies subserve the transmission of accurate tactile impressions to the nerves, may not be better understood than the precise function of the cochlear or vestibular nervous apparatus in the ear. Wagner supposes,

Fig. 5. Papillæ and Corpuscula Tactus, after Wagner. 400 diameters.

that his *corpuscula tactus* on the surface, and the Pacinian bodies more deeply seated, absorb all the terminal filaments of the sensitive nerves, and thinks it possible that they may be connected severally with different modes of sensation; one with the appreciation of heat, for instance, and the other with touch, properly so called. At all events, that the peripheral extremities of the sensitive nerves should terminate in distinct *organs*, and not be merely lost in *tissue*, is a result which ought not to prove surprising.

SURGERY.

DIVISION OF NERVES IN FACIAL NEURALGIA.

In neuralgia, especially of the face, division of the affected nerve has been recommended and practised by many surgeons: as Mr. Haighton, Sir Astley Cooper, etc. The plan practised has been the division of either of the branches of the fifth nerve, at the point where they come out in the face; and some have removed a portion of the nerve. M. Roux's plan, which we will presently describe, differs somewhat from these.

For an outline of the views of various authors, and some very judicious remarks on the subject, we would refer our readers to the late Professor Samuel Cooper's *Surgical Dictionary*, article NEURALGIA. The following observations by Dr. Watson (*Lectures on Physic*, 3rd edit., vol. i, p. 712) are worthy of attention.

"One of these topical expedients, which promised well when first thought of, is the division of the trunk of the painful nerve, so as to cut off the nervous communication, through that main channel at least, between the painful part and the brain. This was originally proposed by Dr. Haighton, and was at first attended with some little success; but in a great number of instances it has signally failed, as indeed might have been expected. In one case, the several branches of the fifth pair were cut by Sir Astley Cooper; but in vain. When there is any reason to think that the disease has a constitutional origin, or even a local *distant* origin, the division, or even the excision, of a part of the nerve must be perfectly useless.

"Nevertheless, there are cases in which the division of the nerve, or some other surgical operation may be required. If you can make out that there is any tumour pressing upon or adherent to some part of the nerve; or if some foreign body, as a splinter or a shot, should be ascertained to be in contact with the surface of the nerve, or to be entangled in its substance; the tumour or the foreign body may be removed by the knife, with the strong expectation that a cure will be thus effected."

DR. JULES ROUX, of Toulon, in a memoir published in *L'Union Médicale* for Oct. 5th, 12th, 26th, and 28th, 1852, describes a new process for performing resection of the nerves in facial neuralgia. He observes that the following means have been recommended, when medicine has proved powerless to arrest the disease: 1. Section: 2. Cauterisation: 3. Resection. Simple

section of the nerve, as advised by Maréchal, André, Boyer, etc., is too often unsuccessful in preventing a return of the disease, when the divided nerve has become reunited. The same remarks apply to subcutaneous division, notwithstanding the assertions made by M. Bonnet of Lyons.

Light and frequently repeated transcurent cauterisation of the skin, as practised by M. Valleix, is useful, but not always successful.

Resection or removal of a portion of the nerve is held by Dr. Roux to be most frequently successful: but it is not infallible. He has arrived at the following conclusions from an observation of eleven cases, in which he performed resection of the trifacial nerve:

1. In facial neuralgia, resection of the nerve behind the painful branches, or between the terminal branches and the origin, may triumph over the disease.

2. A cure may be effected, even when some neuralgic branches have been left behind the excised portion, on the part of the nerve nearest its root.

3. When two or three branches of the trifacial nerve are affected in succession, the resection of the branch which was first affected is often sufficient to cause the disorder to cease.

4. Under other circumstances, when the branches remain still painful, it is necessary to operate on two of them.

5. After resection of a branch of the trifacial, the pain, though abolished in the terminal branches, may still continue behind the part operated on, and in other branches proceeding from the nerve.

6. Neuralgic sensations, similar to those felt after amputation of limbs, may appear at a longer or shorter interval after resection has been performed.

7. The loss of sensation in certain parts of the face, which follows resection of the branches of the trifacial, is likely to disappear some months after the operation, without recurrence of the neuralgia.

8. When, after resection of the infra-orbital or mental nerve, for instance, pain reappears behind the part operated on, one branch only may be affected, the cure remaining complete in the others.

9. When both sides of the face are neuralgic, resection of the nerves of one side has no effect on the neuralgia of the opposite side.

The only two cases of resection which Dr. Roux finds described, are related by M. Bérard in the *Journal des Connaissances Médico-Chirurgicales* for 1835, p. 441.

Dr. Roux's new operation is founded on the principle, that the nerve must be sought for in the bony canal through which it passes, or at the foramen from which it emerges. He proposes that, the patient having been put under the influence of ether or chloroform, a curved incision, with the concavity directed upwards, should be made through the soft parts down to the bone. The foramen is easily found: 1. By anatomical knowledge of its position: 2. By hæmorrhage from the artery which accompanies the nerve: 3. By passing a probe into it: 4. By the nervous filaments which can be seen in its vicinity: 5. By the pain, if the patient is not sufficiently under the influence of the anæsthetic. Whenever practicable, he exposes the canal in which the nerve runs by means of a trephine; and then excises a portion of the nerve, from three to five millimètres in length (from about one to two inches). He then applies the cautery, at a white heat; and sometimes also pushes back the end of the nerve with a blunt probe. Before dressing the wound, he detaches the periosteum round the foramen, in order to be certain that no nervous filament has escaped. The hæmorrhage produced is in general readily arrested. After the operation, there is always local paralysis of sensation: and sometimes also some paralysis of motion; but this is slight, and disappears in time.

M. Roux describes his methods of operating on each of the branches of the trifacial.

Resection of the inferior dental nerve in its canal. A flap is made, commencing from the anterior edge of the masseter, in front of the facial artery, and extending to near the mental foramen. The canal is opened by a small trephine, and the piece of bone raised. The blood is wiped away, the nerve exposed, and excised by means of scissors or a bistoury in the whole extent which has been laid bare: and the cautery is applied. Sometimes the dental canal is double; but then there is only a thin osseous plate between the two canals. The hæmorrhage from the inferior dental artery is but slight, and is easily arrested by cauterisation, or by the introduction of a few filaments of charpie.

Resection of the mental nerve. The foramen having been exposed, Dr. Roux excises as much of the nerve as can be found,

and introduces several times the cautery into the foramen, as far as the branch of the dental nerve which goes to the incisor teeth. If the foramen is too small to admit this, he finds it necessary to apply the trephine, and excise and cauterize the inferior dental nerve in its canal, before its division.

Resection of the infra-orbital nerve. This is performed by excising as much of the nerve as is exposed, and introducing the cautery into the foramen, or into both, if, as sometimes happens, there are two.

Resection of the supra-orbital nerve is performed in an analogous manner.

Resection of the superior and posterior dental nerves. The operation is here more complicated, from the deep situation of the nerves. The upper lip must be well supported, the gingival fold incised, and the antrum of Highmore trephined behind the canine fossa: the gum, and, if possible, the lining membrane of the sinus, must be raised: finally, the segment of the maxillary tuberosity, where the dental canals are present, must be removed. In this way, the operation seems simple and free from danger.

Resection of the anterior half of the inferior dental nerve: M. Beau's process. The operation is performed as in Dr. Roux's process; then the ends of the nerve, appearing at the hole made with the trephine, and at the mental foramen, are seized, and the nerve between them pulled backwards and forwards, so that the connexion with the dental branches is broken, and the nerve pulled out through the mental foramen.

Resection of the posterior half of the inferior dental nerve: M. Beau's process. A trephine is applied below the sigmoid process, and below the second molar, and the intervening portion of nerve is extracted. Dr. Roux, allowing that this process is ingenious, fears that it may give rise to inflammation and diffuse suppuration.

The following is an analytical table of six cases operated on by Dr. Roux:

No.	Name.	Age.	Parts affected.	Duration of Disease.	Nerves divided.	Time after operation.	Result.
1	D.	74	All the branches of 5th pair on both sides.	30 years	Right inferior dental and infra-orbital.	15 months	No return in infra-orbital: return in dental after six months.
2	C.	68	All branches of 5th pair on right side.	15 years	Right infra-orbital.	8 months	Complete cure.
3	J.	69	Ditto.	34 years	Ditto, and mental.	8 months	Do.
4	D.	63	Ophthalmic and superior maxillary on left side.	8 years	Left infra-orbital.		Failure. Patient has been much relieved by transcurent cauterization.
5	G.	25	Infra-orbital & mental nerves of right side.	5 years	Nerves affected.	7 months	Cured.
6	S.	70	All branches of 5th pair on right side.	22 years.	Mental and inferior dental.		Do.

A case of severe neuralgia of the inferior dental nerve, is re-

ported in the Hospital Mirror of the *Lancet*, for October 23, 1852, as having been successfully operated on by Mr. FERGUSSON. He performed subcutaneous incision of the nerve at the point where it emerges from the mental foramen on the right side. Some weeks after the operation, the patient went out, cured, at least for a time.

ASSOCIATION INTELLIGENCE.

NOTICE TO MEMBERS:—PAYMENT OF SUBSCRIPTIONS.

MEMBERS who have not yet paid their Subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Treasurer (Sir CHARLES HASTINGS), or to the Secretary of the Association, at Worcester. Gentlemen, joining the Association, are required to observe the 24th rule, which states, that "each member is to pay one guinea annually; and that the subscription commences on the 1st of January in each year, and must be paid in advance."

JAMES P. SHEPPARD, Secretary.

ADDRESS ISSUED BY THE JOURNAL COMMITTEE IN SEPTEMBER LAST.

The Committee appointed at the anniversary of the Provincial Medical and Surgical Association, held at Oxford, July 21st, 1852, with full powers to make the necessary arrangements for editing and publishing the Journal in London, avail themselves of the earliest opportunity of submitting to the profession the following scheme of publication, and of earnestly requesting co-operation and support.

Of the great superiority of such a periodical, both as regards economy and independence, over every similar undertaking of a merely commercial character, there cannot be any reasonable doubt; and the opportunity now presented of raising the standard and improving the tone of our medical periodical literature is one we should eagerly embrace.

The Committee are glad to be able to state, that the New Series will have the support of a greatly augmented staff of London and provincial contributors, the proprietors of the *London Journal of Medicine* having consented to withdraw their periodical, and to transfer their influence to the JOURNAL OF THE ASSOCIATION; while in Dr. CORMACK they have found an Editor, whose long experience, acknowledged talents, and high literary qualifications, eminently fit him for the post.

It is intended that the new Journal, while it retains its original character as the organ of the Association, should secure, at the lowest possible expense, all those advantages which a weekly periodical is capable of affording; and that it should, by presenting a faithful Digest of Medical Literature and Science, as well as an attractive summary of Professional News, render the purchase of any other periodical a matter of choice rather than of necessity.

The contents of each number will be usually classed under the following principal divisions:—

- I. LEADING ARTICLES.
- II. ORIGINAL COMMUNICATIONS.
- III. BIBLIOGRAPHICAL NOTICES.
- IV. PERISCOPIC REVIEW.
- V. REPORTS OF SOCIETIES.
- VI. ASSOCIATION INTELLIGENCE.
- VII. NEWS AND TOPICS OF THE DAY.
- VIII. OBITUARY.
- IX. APPOINTMENTS.
- X. EDITOR'S LETTER BOX.
- XI. ADVERTISEMENTS.

The Annual Subscription to the Association is One Guinea; which, in addition to the supply of the Journal, postage free, includes the other privileges of membership. All legally qualified members of the medical profession (*being regular practitioners*) are eligible.

The necessary information may be obtained by applying to the General Secretary, JAMES P. SHEPPARD, Esq., Worcester; to any of the local Honorary Secretaries; or to Dr. CORMACK, Putney, London.

In conclusion, the Committee would simply observe, that if the profession prove true to its best interests, the scheme which they have now the honour of proposing must result in effects of great and lasting importance.

CHARLES COWAN, M.D., Chairman.

London, Sep. 20th, 1852.

NEW SERIES OF THE JOURNAL.

THE JOURNAL COMMITTEE, appointed at Oxford, have decided that the usual size of the Journal shall be twenty-four pages; but that, when there is a pressure of advertisements, or of important matter which cannot be conveniently delayed, a larger sheet may be occasionally afforded.

CHARLES COWAN, M.D., Chairman.

METROPOLITAN COUNTIES BRANCH:—FIRST GENERAL MEETING.

LONDON, DEC. 22, 1852.

NOTICE. Members of the Association residing within the county of Middlesex, and such parts of Essex, Surrey, Herts, and adjoining counties, as are not included in any existing Branch, are requested to attend the First General Meeting of the METROPOLITAN COUNTIES BRANCH, to be held on Tuesday, January 11th, 1853, in the Hanover Square Rooms, at half-past Two o'clock P.M. Members are invited to bring their medical friends with them.

T. OGIER WARD,
Hon. Sec. to the Provisional Committee.

NOTICES BY THE EDITOR.

MEMBERS and others are requested to send books, manuscripts, and letters for the EDITOR, to his residence, Essex House, Putney, London; or to the office of the Journal, 87, Great Queen Street, Lincoln's Inn Fields, London.

Dr. CORMACK will attend at the office, to receive members, every WEDNESDAY, from four to a quarter past five, p.m., when not unavoidably prevented by other duties.

The commercial business of the JOURNAL is transacted by the publisher, every lawful day, at the office, between the hours of nine A.M., and seven P.M.; and, to prevent delays or mistakes, it is particularly requested that all advertisements and letters connected with the alteration of addresses, or with the commercial department, be addressed to the publisher, Mr. THOMAS JOHN HONEYMAN, and not to the editor.

RECENT DISCUSSIONS IN THE BATH AND BRISTOL BRANCH. We have received many letters upon various topics connected with the case of BOURN v. COX. We cannot, without the authority of the Council of the Association, insert any of them, as they refer to personalities. We will transmit these letters to the Council, should their respective authors wish us to do so.

EDITOR'S LETTER BOX.

PROPOSAL TO RENDER THE ORGANIZATION OF THE ASSOCIATION USEFUL IN THE STUDY OF EPIDEMIOLOGY.

LETTER FROM DR. MILROY TO THE EDITOR.

SIR,—On perusing the Prospectus of the New Series of the Journal, it has occurred to me that it might be made the channel of much valuable information on a subject which has not hitherto received the attention which its importance deserves, viz.: the NATURAL HISTORY OF EPIDEMIC DISEASES. This work can, of course, only be carried out by a number of observers in the different parts of the kingdom accurately noting down a few simple facts at the time of their occurrence, and transmitting them to you, for the purpose of being registered and made public at periodic intervals in the pages of the Journal. Such information would form a new, and, as seems to me, a very valuable feature of the Journal of an Association whose members are wide-spread over the country, and which has already done good service to the profession in matters requiring extensive co-operation.

The object contemplated is to ascertain and record the leading circumstances connected with the development and spread of Epidemic Diseases; and the following points have suggested themselves to my mind, as among the most important to be attended to in conducting such an inquiry:—

The exact date of the occurrence of the first case of an epidemic disease (whether the case terminated favourably or otherwise) in any town, district, or locality. It is of the ut-

most consequence to determine this point with undeniable accuracy; unless it be so, the most important link in the chain of evidence respecting the origin of the epidemic will be wanting. Too much stress cannot, therefore, be laid upon the exact determination of the day when the first patient sickened. Along with the name, age, and occupation of the person, the locality of the abode, its sanitary condition, the number of the inmates, etc., should be given. Then, too, was he a stranger who had recently arrived from some other place, or was he a resident who had not been away for a length of time? If the former, was the disease with which he has been attacked, existing in the place whence he came? when did he leave it? and when did he take up his present abode?

The exact date and locality of the *second* case. Did it occur in the same house with the first? If not, what is the distance between the two? Had there been any communication, direct and personal, or indirect and intermediate, between the patients? Second-hand information upon this point should seldom or never be received; to be trustworthy, it must always, if possible, be derived from the patients themselves by the medical attendant, who has thus an opportunity of ascertaining, by cross-examination, its credibility. Hearsay evidence upon such matters as the present is much more likely to mislead than to be useful. When communication is alleged or suspected, it is well to ascertain how other persons, who may equally have communicated with the first patient, have fared. Were they subsequently attacked, or did they escape? Did they convey the disease elsewhere? Did the medical attendant suffer? etc. If a similar line of inquiry were pursued respecting the next case or two, a good and sure foundation would be laid for observations on the future course and extension of the disease, and a very material step be taken in the solution of the interesting problem. How did it originate? Was it distinctly traceable to material introduction *ab extra*? or did it develop and introduce itself, we cannot tell how? Mere speculations and conjectures upon such a topic are to be avoided.

I would here suggest, in passing, the importance of medical observers keeping their minds more free, than perhaps they usually are, from any preconceived opinions as to the part which Contagion, that is, transmissibility from the sick to the healthy, plays in the appearance and diffusion of epidemic diseases. It may be that some diseases, not usually regarded as propagable in this way, are so to a certain extent; and that other diseases, acknowledged by all to be so, have nevertheless the power of developing and diffusing themselves irrespectively of any direct and traceable intercommunication. At all events, there can be no doubt that a series of accurate observations in numerous districts over the kingdom, continuously recorded for a few years in succession, would throw much light on this and other vexed questions in medical science, and would probably lead to greater uniformity of opinion on matters in which the credit and usefulness of our profession, as well as the public welfare, are involved. The great object to be had in view is to collect a large number of authentic and well-sifted facts, without regard to any doctrine and hypothesis for the present. What has been done for meteorology and astronomy by the concurrent observations of inquirers in different and distant localities, must be done by epidemiological students, before we can hope to attain to the discovery of any general truth respecting the laws which regulate the outbreak, course, and spread of zymotic disorders.

The mention of meteorology reminds me to suggest that it would add much to the interest and value of accurate data on the points already mentioned, if short notices were given at the same time of the state of the weather, etc., immediately preceding as well as accompanying the appearance of such diseases, and the seeming influence which atmospheric changes and peculiarities had upon their type, severity, and duration. Then, too, it would be highly interesting to know whether any blights or murrains existed about the same period, and to learn something about their nature and leading characters.

Sometimes the outbreak of an epidemic is preceded by the unusual prevalence of other disorders, or by a notable change in the ordinary characters of endemic diseases. Thus, diarrhoeal and dysenteric complaints have often been observed to usher in an epidemic invasion of bad remittent fever, in countries where this is endemic; and cholera, it is well known, has very generally gone before the manifestation of the developed pestilence; while the remarkable alteration in the type of the ordinary fever of Brazil, which had been observed for three or four years (I believe) prior to 1850, forms one of the most interesting facts connected with the history of the recent appearance of yellow fever in that country. It is, therefore, of consequence that attention be drawn to what precedes as well as to what accompanies the ap-

pearance of epidemic disorders, more especially when these are only occasional, and recurrent at distant intervals of time.

It is obvious that, if once a system of regular observation and record were established in different parts of the country, many points of great interest would stand a fair chance of being more satisfactorily cleared up than, as far as I know, they have hitherto been. Thus, the average duration of epidemic outbreaks in a locality; the ratio of seizures to the population, and of deaths to the numbers attacked; the influence of topographic and domiciliary conditions, in private life as well as in public institutions, on the results; the probable duration of the incubative stage, and the comparative frequency of secondary attacks; the intervals between successive outbreaks of different epidemics; the seasons of the year at which they usually appear; their migratory course and geographical distribution, etc., would all eventually come in for their share of elucidation. The exceeding value of the Registration, as carried out during the last fifteen years in England and Wales, is recognized by every one interested in the advancement of medical science, and in the promotion of the public health; but by itself it is necessarily an imperfect record, as it forms but a part of a larger and more comprehensive scheme of inquiry. Might not the plan suggested above be usefully supplemental and ancillary to it, as regards that most important class of diseases known by the general appellation of zymotic? As I have already remarked, it can only be made effective by the concurrent labours of numerous observers, steadily continued for a length of time, and regularly made known by periodic publication.

I remain your obedient servant,

G. MILROY.

London, Dec. 15th, 1852.

THE MEDICAL BENEVOLENT COLLEGE.

LETTER FROM DR. BARKER TO THE EDITOR.

SIR,—To defend a benevolent institution against objections brought forward by one of the most benevolent and noble-minded men in the profession, is a rather singular task. It is not pleasant to differ, even in opinion, from one for whose character we have the highest esteem; but benevolence itself may err in its plans, and this, we believe, is the case with regard to the views of MR. NEWNHAM, of Farnham, respecting the proposed "Medical Benevolent College". It is evident, from his letters published in the Journal for Oct. 13th and 27th, that MR. NEWNHAM partially distrusts the plan of the College, and would, in opposition to it, press on our notice the claims of the "Medical Benevolent Fund". Now, the simple difference between ourselves and MR. NEWNHAM is, that we do not see the necessity of any such opposition; we say, "Success to the Medical Benevolent Fund", and also, "Success to the Medical Benevolent College". There will be ample room for both, and we have a trust that both will be liberally supported. It has been observed, that a little difference in character may strengthen a friendship between two persons. Now, the difference between these two institutions is, we think, nothing more than will admit of perfect amity and beneficent co-operation. Each has some advantages which the other does not possess. They may be considered rivals, but only in the glorious endeavour of doing the utmost possible amount of good; and here, the more spirited the rivalry, the better for both. Let every benevolent man support both institutions if he can; or, if he can only give his aid to one of them, whichever that may be, he may rest assured that his patronage is bestowed upon a most worthy object.

Having made these few general remarks, I will venture to notice more particularly the doubts which MR. NEWNHAM expresses concerning the plan of the Medical Benevolent College. The most tangible of the objections mentioned in the letters, is that against the investment of so much money in "bricks and mortar"; or, in other words, in building, according to the plan laid out for the Benevolent College, *first*, an Asylum, or Home, for one hundred pensioners, being duly qualified medical men or their widows; *secondly*, a School, in which a liberal education will be given to one hundred boys, the sons of duly qualified medical men; and *thirdly*, a Chapel. Such is the scheme contemplated by the benevolent mind of MR. PROPERT, and now, by his unwearied exertions, brought so near to a successful issue. Between this plan and that of the Medical Benevolent Fund, the difference is simply this, that the latter gives an annuity, while the former proposes to give an annuity *with a house*. The money invested in "bricks and mortar", if invested in *consols*, as MR. NEWNHAM prefers, would surely go partly to pay rent when distributed in annuities; but excepting the case of a lavish expenditure in building, which will certainly not take place, we cannot

see any force in the objection raised against spending a portion of the funds in providing houses for those who require them; and we maintain, that, with due regard to economy, a smaller outlay in building will be required, than if money were to be invested in consols, for the purpose of supplying each annuitant with the rent of an equally commodious house.

MR. NEWNHAM implies a distinct objection against the plan of the College, when he speaks of "home" as the only place for the development of the "sympathies of relative kindness and the affections of a family". This objection would have weight if it were a part of our scheme to discourage all assistance at home; but this is far from being the case. Undoubtedly, there will be cases where, on account of particular family ties, removal from home would be objectionable; but what follows? Simply, that these are the cases for which the modes of relief adopted by the distributors of the Fund will be especially applicable. On the other side, we must remember, that many medical men, in the time of affliction and adversity, would prefer removal from the scenes of their former prosperity. Here we think that the remarks of MR. NEWNHAM only serve to show how desirable it is that we should have *two* benevolent institutions, ruled by the same spirit, but so far differing in character as to accommodate the two classes of recipients. We might here notice several points, to show that MR. PROPERT's plan will afford a "home" such as many will be glad indeed to find. We might speak of the true "*otium cum dignitate*" which the decayed medical man will here find in his removal from painful associations and contrasts; of social intercourse with genial minds; of the gathering of friends and relatives around the asylum, and the formation of new friendships in the neighbourhood; of settling children within an easy distance; and, lastly—no trifling feature in the beneficent scheme—the delightful absence of all care about rent and taxes!

The town in which I reside, Bedford, is a favourable place for showing the advantages of such "homes" as are to be provided in the College. Here I do not speak on mere theory, but am daily witnessing the happy results of a plan similar to that proposed by MR. PROPERT. I know that in such "homes" as we have here, the annuities granted by a noble charity may be expended with the greatest advantage; and I can safely say, that I have never seen or heard of any of the supposed probable disadvantages to which MR. NEWNHAM has alluded.

The respected Treasurer of the Benevolent Fund objects also to the "canvassing system", though it has been found to work well in other institutions. The influence of wealthy patrons in securing elections, is one of the modes of charity, liable, indeed, to some exceptions, but, on the whole, good, as calling forth such an amount of active interest and support as could not be expected on any other plan. The rule, that a subscription gives to the subscriber a voice in the election of recipients of the charity, and that the number of votes will be in the ratio of amount of subscription, is so gratifying to many wealthy patrons, that I will venture to say that, if this mode of election were discarded, a great amount of pecuniary support would be withdrawn. We may regret the fact, but we must allow it to be quite reasonable that patrons should expect to have some control over the distribution of the funds, to which they liberally contribute. As MR. NEWNHAM says, "Man's motives are seldom, if ever, perfectly single". Well, then, we must not expect anything superhuman, but must simply endeavour to call forth the greatest amount of human benevolence, and be very thankful for it. We must remember, also, that there will be an executive council for regulating the qualifications of candidates—ultimately, in all all probability, to have the entire control of the admissions; and I see no reason to apprehend that the discontent and other lamentable results, predicted by MR. NEWNHAM, will be likely to attend the elections.

Another objection is founded on the "pride" of our profession. I am not aware that in this quality we abound more than our legal or clerical brethren, among whom institutions like that now in question have succeeded well enough.

After all these misgivings, MR. NEWNHAM wishes that the experiment may succeed; but this kind wish is expressed in what we must call a faint-hearted style, as in the same breath he advises his readers to "be cautious"; to remember, that, though the College "has a name", it has "as yet no local habitation"; that "its advantages are all hypothetical"; and "they have not yet been proved". This is certainly a rather cool mode of wishing success to a scheme. With regard to the College, MR. NEWNHAM has indeed "dropped the character of the advocate".

Esteeming, as I do most highly, the character of the Christian Treasurer of the Benevolent Fund, I have still ventured to make the above remarks, because I believe that, in zeal for his fa-

vourite institution, he has been led to depreciate a plan which, under God's blessing, promises to have an immense amount of good as its result.

With all the general remarks on the duty of benevolence, and with the excellent advice addressed to young professional men on prudence and foresight, all who have read MR. NEWNHAM's letters must heartily concur. Our first duty is to prevent calamity; our second, to afford relief. However we may insist on providence and self-help, we must also remember that benevolence must always have a part to play in the affairs of this life. The relations of mankind to each other can never be reduced to a simple debtor and creditor account in a commercial sense; but the Giver of all good things, to whom nothing can be immediately returned, has commanded that our debt to Him shall be ever practically acknowledged in acts of charity towards our necessitous brethren.

To dwell on the peculiar trials and claims on sympathy which may be found in our profession, is not required, after the faithful picture of hard struggle and failure given in one of the letters, and evidently drawn from the life. With such cases so frequently coming under our notice, who can doubt that there will be ample scope for exertion in both the institutions now compared together? What we want now is, not any further discussions on their relative merits, but friendly co-operation and a determination to support both, as far as our means will allow. Private and special exertions, such as were lately employed in a case of great affliction and distress occurring in this town, cannot be expected to succeed so well in all cases. Hence the necessity for some permanent provision for the relief of really necessitous and worthy cases. After all that the proposed College can do, there will be wide scope for the patrons of the Fund in affording temporary relief in many cases of distress, where a permanent provision may not be required; or in other urgent cases, when some delay must occur in providing for the sufferers permanent homes in the College.

To conclude: no provisions that may be made for the relief of unavoidable distress should for a moment lessen our attention to all the means required to maintain independence. Strict calculation, provident habits, life-assurance, and all other prudential means, must be employed to avert the evil day; but as it may come and will come for many, after all their best exertions to avoid it, we sum up the whole purport of our remarks by heartily wishing success to the Medical Benevolent College, and success to the Medical Benevolent Fund! Let them never be mentioned as rivals: rather let "*hand-in-hand*," or *unum alterius eget*, be their common motto.

T. HERBERT BARKER, M.D.

Bedford, December 8th, 1852.

THE MEDICAL REFORM BILL:—HOW ARE WE TO PREVENT ILLEGAL PRACTICE?

TO THE EDITOR.

SIR,—I perceive that the Medical Reform Committee of the Association are still desirous of receiving suggestions relative to the amended Medical Bill. I think it effective in most points, particularly in the clauses referring to the registration of legal practitioners; nevertheless, it appears not to determine who shall be the prosecutors of *illegal practitioners, such as prescribing druggists and others*, who practise medicine very extensively, because their qualified neighbours do not like to make it a personal business in prosecuting them.

Unless some clause can be introduced into the present Medical Bill (as suggested by a correspondent of another Journal), to empower Government *excise officers* to prosecute and obtain fines from those who practise medicine illegally, I fear the measure will not, in the end, be of much benefit to the qualified practitioner. I therefore wish to call attention to a letter in the *Lancet* of Dec. 4th, signed "A General Practitioner", which appears to suggest a very effectual remedy for prohibiting pharmaceutical chemists, druggists, and others, from illegally practising medicine; which consists in affording to excise officers the necessary inducement to inform against such persons.

I am, etc.,

A SURGEON AND APOTHECARY.

Dec. 14th, 1852.

PARLIAMENTARY REPRESENTATION OF THE MEDICAL PROFESSION.

LETTER FROM THE SECRETARY OF THE YORK SCHOOL OF MEDICINE TO THE EDITOR.

SIR,—At a meeting of the Lecturers of the York Medical School, the question of the representation of the University of London in

Parliament was discussed; and it was thought that such representation was highly desirable, inasmuch as the medical profession might thereby obtain a more direct voice in public affairs. It was the unanimous opinion of the lecturers, that inquiry should be made as to whether the franchise should be conferred on the teachers in Provincial Schools, irrespectively of their being graduates of the University; and that it would be well to ascertain the opinions and intentions of parties interested. Would you, therefore, by publishing this note, afford me the opportunity of calling the attention of teachers and professors in the Provincial Medical Schools, and of the Committee of Graduates, to this important subject?

I am, sir, your obedient servant,

JAMES ALLEN.

York, Dec. 20th, 1852.

NEWS AND TOPICS OF THE DAY.

YELLOW FEVER AT SOUTHAMPTON.

REPORT OF THE SELECT COMMITTEE OF THE SOUTHAMPTON MEDICAL SOCIETY.

THE close and constant intercourse of Southampton with tropical climates, through the medium of a rapid steam communication, for some time past, has invested the subject of Quarantine with a peculiar interest in this quarter—an interest which has been painfully increased by the sad mortality amongst our countrymen during the existing prevalence of yellow fever in the West Indies. The intensity of the excitement thence arising, suggested to the Southampton Medical Society that the appeal, so frequently made to them individually for an opinion on this important topic, would be best responded to by the report of a select committee appointed by the society. This suggestion was accordingly carried into effect, and your committee now beg to submit the result of their investigation.

The very nature of the subject precluded your committee from arriving at conclusions through a process strictly inductive; but they have endeavoured from the evidence within their reach, to derive such general propositions as appeared the best approximation to the truth. In a word, they had no wish to compromise the interests of science, by pretending that their report had exhausted or could exhaust, the subject; or, that all the evidence possible to be adduced was before them; but they desired to make such practical suggestions, preventive and remedial, as the experience of the disease seemed to warrant.

Your committee do not feel themselves called upon to enlarge on the history of the disease beyond the limits of the circumstances which affect its development and progress at our own port. They, therefore, propose to consider the subject under four heads:—

- I. The natural climate of the disease.
- II. Whether malignant yellow fever is a specific disease, or can be identified with the milder forms of endemic fever common to warm climates.
- III. How yellow fever is propagated.
- IV. What sanitary measures should be adopted.

I. THE NATURAL CLIMATE OF THE DISEASE. In examining the evidence on this point, your committee have not been content to draw a conclusion merely from the direct testimony of those who have witnessed the disease in warm climates. A careful inquiry has been made into the diseases of Northern regions, and it has been found that febrile affections have been, although very rarely, imported into those latitudes in an epidemic form, an instance of which was the introduction of measles into the Faroe Islands in the year 1846. In the Temperate Zone it is well known that some fevers are indigenous, and others have been introduced; but your committee, having reviewed the accounts of the rise and course of every well-authenticated epidemic of yellow fever, do not hesitate to pronounce, from the uniformity of observed instances, that yellow fever is essentially an inter-tropical disease.

II. WHETHER MALIGNANT YELLOW FEVER IS A SPECIFIC DISEASE, OR CAN BE IDENTIFIED WITH THE Milder FORMS OF ENDEMIC FEVER COMMON TO WARM CLIMATES. This is a point upon which the profession is much divided, and it would be equally unprofitable as inconvenient to the members of the society to introduce into this Report the arguments which have

been used on both sides, in support of their respective opinions. But, since your committee intend to answer the question as to the identity of the two diseases, in the affirmative, it is deemed right to refer to a portion of the evidence upon which their judgment is based. Among the writers on the earlier epidemics, the names of Frank, Rush, and Bancroft, may be cited, as maintaining the opinion that the endemic and the yellow fever are varieties of the same disease. The history of the epidemic at Antigua, in the year 1816, as given by Dr. Musgrave, affords, perhaps, the most complete proof on record of the changeable character of yellow fever, and of the facility with which, under favourable circumstances, one form of fever may be converted into another. Again, the account recorded by Dr. Bryson, of the endemic of Sierra Leone, in 1823, may be compared with the subsequent outbreak of fever, and the intense form which it acquired on board H. M. S. Bann; and of a still later date, the case of the *Eclair* presents many phenomena parallel to those which had been observed in the case of the Bann. Moreover, the doctrine of the identity of the milder remittent with the severe form, derives additional support from analogous circumstances, which are ascertained to exist in the course of other febrile diseases.

III. HOW YELLOW FEVER IS PROPAGATED. Taking it for granted, as an empirical law co-extensive with all human experience, that so-called miasma is a cause of endemic fever, and assuming that the milder fever may develop the malignant variety, it will be important to consider whether contagiousness is a necessary quality of the disease, and if not, under what circumstances it will exist. For a solution of this question, your committee again appeal to the testimony afforded by the Report of Sir William Burnett, in the case of the Bann, at the Island of Ascension, in 1823, as well as to the facts brought to light by Drs. McWilliam and King on the appearance of yellow fever at Boa Vista, in 1845. A careful examination of those facts must, it is thought, convince every unprejudiced person that, in those instances, contagiousness was found to be a property impressed upon the disease after the appearance of the malignant stage; but, at the same time, it may be safely admitted that, in numerous cases of yellow fever, no such property has been detected.

The next point is, whether all or any of the conditions necessary for the development of contagiousness have been ascertained. On this point the utmost uncertainty prevails, since the number of observations is limited, and the quantity and distribution of the natural agents of contagion can neither be measured nor examined: nevertheless, it has been held by diligent observers, that science is approaching to a knowledge of such conditions, and that already they are warranted in associating the phenomena of contagion in yellow fever with the presence of certain natural states, such as high temperature, moisture, an atmosphere impregnated with emanations from animal or vegetable decomposition, and a susceptibility on the part of the recipient. But, without attempting to explain the precise office which each condition holds in reference to the result, it may be stated, that the probabilities are strongly in favour of the existence of at least some such conditions, as necessary agents in the propagation of yellow fever.

The solitary fatal case which has recently taken place in Southampton, and which presented unusually favourable circumstances for the action of the contagious principles common to the exanthemata and other fevers of this climate, coupled with the fact that free communication has been allowed between the ships' companies of the *Plata* and *Medway*, and many of the unacclimatised inhabitants of this port, has forcibly impressed your committee with the opinion that it is highly probable either that the conditions necessary for the endemic diffusion of the yellow fever were altogether wanting, or that the full operation of those conditions was prevented by counteracting causes.

From what has been already stated on the subject of this inquiry, the measures which your committee feel called upon to recommend will be easily understood. They are of two kinds—the care of the sick, and the protection of the healthy.

I. THE CARE OF THE SICK. A separation of the sick from the healthy is the first step to be taken, and your committee venture to suggest that this principle should be efficiently carried out on the arrival of all ships with yellow fever on board entering this port. Your committee do not hesitate to draw a marked distinction between the regulations necessary to be observed in the case of yellow fever, and the Quarantine laws which are in force with respect to diseases, supposed to be contagious in all latitudes. They therefore feel justified in recommending, that all persons not affected with this disease, should be allowed to proceed at once from the pestilential atmosphere of the ship, to their respective places of destination; and that a

suitable building should be provided in a healthy situation for the immediate reception of patients labouring under yellow fever.

In offering this recommendation, your committee do not forget that individuals have become the recipients of yellow fever, after having visited infected ships, even in this climate, a fact suggestive of the necessity of observing great caution in the intercourse to be permitted between the shore and an infected ship.

II. THE PROTECTION OF THE HEALTHY. Your committee do not feel themselves in a position to interfere with the medical arrangements of ships belonging to any company. The medical staff of every company is fully competent to manage its own internal affairs; but they think it right to observe, that no ships can be considered fit for the traffic between our own and tropical climates, unless furnished with the means of annulling, as far as possible, the conditions which are supposed to favour the propagation of disease within the tropics.

There is, however, another and a most important point to be noticed, in reference to protective measures; and that is, the sanitary condition of the inhabitants of the town itself. Your committee cannot too strongly urge the absolute necessity of giving every encouragement and facility to the resident officer of health, in his endeavours to remove all the causes which are believed to render persons susceptible of infectious diseases. Your committee feel assured that he will not only direct his attention to the crowded dwellings of the poor, where danger might reasonably be suspected, but that he will extend his observations to the more subtle causes which produce disease in the homes of the rich.

Finally, your committee look with confidence to the result of the adoption of the regulations here recommended. It may be anticipated, that not only will all fear of yellow fever finding the means of extension in this climate be allayed, but that, by carrying out increased sanitary vigilance, an additional security will be given against the future dissemination of ordinary endemic diseases.

G. A. K. LAKE.

Southampton, December 30th, 1882.

[This document did not reach us till we were going to press, but from its importance and interest, we have withdrawn other matter to make way for it. We have received several letters upon the same subject, to which, along with the above report, we may afterwards direct attention.]

THE PARISIAN HOSPITAL OF FOUR NAMES. By a recent decision of the Municipal Council of Paris, the large new hospital lately built in Paris, is henceforth to be called L'hôpital Lariboisière, in grateful recognition of large funds bequeathed to it by a lady of that name. The French are as fond of altering the names of streets and public buildings, as of changing their form of government: and this hospital has within the past few years been successively designated the Hospital of Louis Philippe, the Hospital of the Republic, the Hospital of the North, and the Hospital of Lariboisière.

KING'S COLLEGE HOSPITAL. The building of the new hospital, after having been discontinued for a short time from want of funds, has been lately resumed. The unnecessary, and indeed we may say mischievous multiplication of petty hospitals for the treatment of special diseases, greatly injures the older charities, as schools of medicine, by withdrawing funds and cases; both are required—the former in abundance, and the latter in variety—for efficient clinical teaching.

THE ASSOCIATION MEDICAL JOURNAL is published at its own office every Friday evening.

SCALE OF CHARGES FOR ADVERTISEMENTS:—

For seven lines and under . £0 6 0	For a whole column . . £2 15 0
For every additional line . 0 0 6	For a page . . . 5 5 0

NEW WORK ON CONSUMPTION.

Just published, in One Volume, 8vo., price One Guinea.

A Treatise on Tuberculosis, the Con-

stitutional Origin of Consumption and Scrofula. Comprising—The Peculiarities of the Tuberculous Constitution; the Signs and Symptoms of Tuberculosis; the Chemical, Physical, and Microscopical Properties of Tubercle and Tubercular Deposits; the Special Pathological Anatomy of Tuberculosis, with an Account of the Deposit of Tubercle in the various Tissues and Organs; the Causes; the Theories which have prevailed in different Ages of the World on the essential Nature of the Disease; the Theories of the Present Day; the Reciprocal Influence of Tuberculosis and other Blood Diseases; the Forms and Varieties of its Local Development; the Diagnosis, Prognosis, Prevention, and Treatment. With Statistical Tables of the Prevalence of the Disease in this and other Countries, and of its relative frequency according to Sex, Age, Occupation, Locality, Season, and Climate. By HENRY ANCELL, late Lecturer on Materia Medica and Therapeutics, and on Medical Jurisprudence, at the School of Anatomy and Medicine adjoining St. Thomas' Hospital; Author of "Lectures on the Blood and other Animal Fluids," and of "Commentaries on the Doctrines of Dr. Justus Liebig," published in *The Lancet*, &c., &c.

London: LONGMAN, BROWN, GREEN, and LONGMANS.

TO SURGEONS, DISPENSING CHEMISTS, ETC.

Sulphate of Quinine, pure Crystal-

lized, prepared by EDWARD HERRING, for the use of Hospitals, Dispensaries, Surgeons, Dispensing Chemists, etc.

This Sulphate of Quinine is chemically pure; its form of Crystal is the same, and in every respect identical with the Sulphate of Quinine of commerce, the only difference being that the one is bleached, the other unbleached.

It has been successfully introduced for the use of Hospitals, Dispensaries, and Public Charities; but its purity and great reduction in price are now attracting the attention of Medical Men and Dispensing Chemists.

The peculiar mode of preparing the Hospital or unbleached Sulphate, and also the usual white Sulphate, is being made the subject of a Patent; the processes of manufacture will therefore be made public.

It is put up in bottles (free) of 3 oz. and 6 oz. each, capsuled with the name of the Proprietor, and labelled with the name of the Inventor.

Both these Sulphates to be had of the leading Druggists in London, and the United Kingdom, and in quantities of not less than 100 ounces of JACOB HULLE, Jun., Proprietor, Chemical Works, Trinity Street, Southwark, London.

Just published, post 8vo., cloth boards, price 3s. 6d.

The Young Wife's Guide during

PREGNANCY and CHILD BIRTH, and in the MANAGEMENT of the INFANT. By HENRY DAVIES, M.D., Fellow of the Royal College of Physicians, and Consulting Physician to the British Lying-In Hospital.

"A very useful little manual by a very experienced accoucheur."—*Lancet*.

HENRY G. BOHN, 45 and 46, York Street, Covent Garden.

Shortly will be published, in 8vo., with 140 Illustrations.

Bullock's Semola.—A highly nutri-

tious and very agreeable Food for Infants, Ladies who are Suckling, and Invalids suffering from any form of debility.

This preparation recommends itself to the Profession by its uniform and known composition, and its accordance with established physiological principles. It consists of the staminal principle of wheat—the gluten—denuded of starch, as far as possible, to leave an agreeable food adapted to cooking.

Many leading Physicians and Accoucheurs now recommend it, and their report is uniformly most satisfactory.

For Weakly Children, Mothers who are Nursing, and Invalids generally, it is invaluable. Many Infants have been fed on it exclusively for some months, and with the best results.

BULLOCK'S SEMOLA is a most agreeable substitute for gruels. It may be cooked in a variety of ways, for which directions are given.

In Packets, 1s., 3s. 6d., and 7s. 6d.

BULLOCK, Operative Chemist, 22, Conduit-street; and may be ordered of all Chemists and Druggists, and in the usual way through the Wholesale Houses.

LONDON: FRIDAY EVENING, JANUARY 14, 1853.

NEW SERIES.

PSYCHOLOGY, AND THE CLAIMS WHICH IT HAS UPON OUR ATTENTION.

THERE are in this country about twenty thousand individuals labouring under various forms of mental disease, secluded and constantly subjected to the close and clinical observation, if not to the treatment of a special class of medical men. There is double this number mixed up with the general community, whose malady is compatible with a certain amount of liberty and usefulness, but who frequently require the aid of medicine, physical or moral; whose condition must influence the health and happiness of all those with whom they are brought into contact; whose presence complicates all social arrangements; and whose passions, peculiarities, and tendencies—in fact, the symptoms of whose disease are incessantly bringing them into violent collision with the laws and conventionalities by which other men are guided and governed. There is, besides, the inevitable occurrence of new cases in a ratio to the population—a suspected actual increase of this class of diseases, and a well ascertained modification in their character, curability, and mortality. There is a distinct literature of this branch of medicine. There are regular reports of the experience in the hospitals, where insanity exists chiefly in its chronic form. There are systematic treatises and monographs on the disease as it is met with in private practice. There are periodicals exclusively devoted to the consideration of psychology and congeneric subjects, in almost all the European languages. Upon these grounds alone, it has been conceived that this Journal would be incomplete, were it not to contain, from time to time, a yerscope of the progress of Psychological Science. But there are other and even more important reasons than these for devoting some space to condensed expositions of our knowledge and our ignorance, our acquisitions and our deficiencies, in this wide and widening field.

IN the *first* place, our pages are intended for that great body of the profession engaged in general practice, and into whose hands the care of almost all cases of nervous disease primarily falls—and falls at that critical period when restoration to health is most practicable, when therapeutical means are most potent, and when all is lost or won of human reason and lifelong usefulness, by a well advised or injudicious application of these means. In the *second* place, from various causes, this class of diseases is less generally and thoroughly understood than others to which flesh is heir, simply because they have been less studied. They were long looked upon with awe and superstition; and were accordingly shunned. They were found to be protracted in duration, and intractable to certain orthodox means, and were abandoned to the efforts of nature, and, what was worse, to the efforts of empiricism. The immediate transference of such cases to places of seclusion has divested them of much of that interest which they would otherwise have possessed, has cut short observation, and has lessened the sense of responsibility of the professional man. And the total absence of clinical instruction, after

confinement had been resorted to, has, until lately, debarred the majority of practitioners from access to, practical acquaintance with, or comprehensive views of diseases, which they only encounter to fear or to fly from. These disorders have consequently not been investigated, and have been consigned to the care of a distinguished, but limited section of the profession. While it is very obvious, from a consideration of the nature of the symptoms of aberration, and of the utility of seclusion as a means of cure, as well as a condition necessary for the application of almost all other means of cure, that this must, to a certain extent, continue to be the case; it appears to be eminently desirable, that the true principles upon which such affections are curable or mitigable should be generally known; that every advance towards a more perfect pathology should be announced; that the labours of the few should be accessible for the use of the many; and that the conditions of the nervous system should be as familiar, and as much under the control of every well-educated practitioner, as the conditions of the lungs or of the uterus. In the *third* place, it is exceedingly probable that the doubt and difficulty, if not the ignorance, which confessedly exist as to mental disease when occurring in general practice, are the results of the combined influence of erroneous views of spiritualism upon the one hand, and of solidism on the other. It has been a fashion to regard aberration of intellect and perversion of sentiment, as conditions of our spiritual nature, rather than as indications of bodily disturbance, as amenable chiefly, if not solely, to moral agencies, and as removed beyond the influence of remedial agents, and almost beyond the sphere of the physician. It has further been a fashion, especially of late, to regard all deviations from healthy mentalisation as arising from disease of the brain. There is truth in these errors. But the whole truth appears to be, that mental disturbance, depending, it cannot be questioned, upon some abnormal cerebral condition, should be regarded as a phenomenon symptomatic of various forms of disease—centric or dynamic, of the solids, or of the fluids, of quantity, or of quality, of immediate, or of remote relations. Insanity is perhaps as often a symptom of albuminuria, of tuberculosis, of anæmia, as of hyperæmia of the vesicular neurine, or of effusion between the membranes. Had the subject been dealt with as it is proposed here to deal with it, and had it been viewed in relation to established physiological and pathological laws, it is highly probable that greater success might have crowned the means of treatment adopted; and assuredly clearer notions would have prevailed as to the course to be pursued, and greater confidence have attended the prosecution of the inquiry. But the vast strides which have been made in bringing our knowledge of the moral nature of man to bear upon its own morbid condition; the great and progressive amelioration in the position of the confined lunatic, which was commenced half a century ago, and cannot again be arrested, afford an additional justification for regularly recording what sorrow or suffering has been deprived of its intensity, what new development has been given to the powers unshattered in the general wreck, or

what new privilege or enjoyment has been found compatible with moral impairment or degradation.

In harmony with these views, it will be our province occasionally to present accounts of all that has been done, or attempted, or proposed in this department; but especially of the observations, opinions, and suggestions, of men actually intrusted with the care of the insane in this and other countries: to place these in practical lights, and to address them to what we know, or conceive, and to what we have felt, to be the wants and wishes of our fellow labourers. If such an apology be deemed unnecessary for what is a desideratum, it has afforded an opportunity of indicating the scope and tendency of the mode in which that will be supplied.

We shall endeavour to display the opinions of the author, rather than our own; to produce all that is original, or place in a new light all that is valuable or interesting, without further commentary than translations or abstracts demand. Condensation is inevitable; but, wherever it is possible, the words of the author shall be employed. It is proposed that all psychological subjects and relations should be embraced; and although the succession in which these will be considered must, to a certain extent, be regulated by the character of the fruits of each publishing season, an effort will be made to impress a unity upon the series, by arranging and harmonising the topics under review, in accordance rather with their natural affinities, than with the order of time in which they may be presented for examination,—so that each article may be, to a certain extent, a consecutive disquisition, and not a mere index of references, or an unconnected group of quotations.

PLAN OF THE PERISCOPIC REVIEW.

LAST week, we described, in general terms, the method which we intend to adopt in the PERISCOPIC REVIEW; which, we stated, "will represent all languages and all departments of medical science". We have likewise in this and the preceding number made some separate observations upon two important divisions of the Periscopic Review,—viz., Microscopical Discovery, and Psychology;—and in an early number we propose in a special article to introduce to our readers the first of a series of occasional Botanical Summaries. In the mean time, however, it may be useful to state the classification of subjects by which we shall generally be guided. Like every similar plan which could be devised, it is purely arbitrary, and is in no way intended to imply, that the study and practice of medicine can, without disadvantage, be broken up into a variety of exclusive pursuits or specialities, as they are usually called. To many, the classification may appear redundant; and we at once admit that it would have been easy to have reduced by more than one-half the number of headings. Microscopical Discoveries might, for example, have been distributed under Anatomy, Pathology, etc.; and Practice of Medicine might have been made to include *Materia Medica*, most of the Diseases of Women and Children, and many Diseases of the Eye and Ear. It has, however, been judged better to adopt the subjoined classification, with all its obvious faults and redundancies, because it is the most convenient for the effective distribution of our staff, and because it enables us to provide for the systematic examination of new books and periodicals, by persons well acquainted with

the practice and the literature of their profession, and who are therefore able to excerpt and criticise the materials which are most likely to be useful to busy practitioners.

THE METROPOLITAN COUNTIES BRANCH.

THE establishment of Branch Societies, composed of members residing within certain defined districts, is one of the wisest and most signal improvements which has been introduced into the constitution of the Association in later years, by its founder, Sir Charles Hastings. The existence of a Branch Society in a district has many advantages; it gathers in new members; it binds neighbours together by a common tie; it affords opportunities, easily available, of meeting together for social and scientific purposes; and it places an admirable check upon irregular practice, and unprofessional conduct. In no part of the kingdom, (as has been long and generally felt), was the establishment of a Branch Society so much wanted, for all the purposes which we have enumerated, as in the Metropolitan Counties; and it is therefore, we feel certain, with extreme satisfaction that the proceedings of Tuesday will be perused by all who desire to see the Association extending its influence, and adding to its numbers. When we reflect upon the importance of the sphere of the operations of this new Branch, the list of those who have already enrolled themselves as members, and the catholic spirit breathed in the speeches of the Chairman and Dr. COWAN, and applauded by those present, we cannot help feeling that the date of the formation of the Metropolitan Counties Branch will be looked back to in after times, as a bright and memorable epoch in the history of the medical profession in these kingdoms. A report of the proceedings of the meeting will be found at p. 43 of this number.

EPIZOOTIC DISEASES.

THE Epidemiological Society of London, established some years ago for the investigation of epidemic diseases, has instituted an inquiry into the nature of the pleuro-pneumonia recently, and, we believe, still prevailing among cattle. Believing that members of the Association might greatly assist the Epidemiological Society by contributing information on this subject, and by inducing their neighbours, professional and non-professional, to do the same, we propose to print in our next number a communication from one of its honorary secretaries, referring to this subject. The inquiry is undoubtedly possessed of great interest and importance, and deserves to be zealously promoted, not only by the medical profession, but by the general public.

ORIGINAL COMMUNICATIONS.

CASES OF EMPYEMA OPENING THROUGH THE BRONCHI:

WITH OBSERVATIONS ON THE CHARACTER OF THE PLEURO-PNEUMONIA WHICH HAS RECENTLY PREVAILED.

By JAMES RISDON BENNETT, M.D., Physician to St. Thomas's Hospital, and to the City of London Hospital for Diseases of the Chest.

CASE I. EMPYEMA OPENING BY THE BRONCHI. RECOVERY. M. T. a gentleman, *æt.* 52, of large frame, active mind, feeble circulation, and who had for some years been the subject of frequent bronchitic attacks, was suddenly seized, after standing in a draught, with severe stabbing pain, running though from the angle of the scapula to the anterior of the chest. This was followed by feverishness, an aggravation, as he supposed, of his usual cough, difficulty of breathing, and muscular pains of the trunk and limbs.

May 13th. I saw him, with my colleague, Mr. Solly, a few days subsequently. He was then suffering still from pain of side, aggravated by motion; cough, attended by mucous expectoration more or less sanguineous and tough; a hot skin and frequent pulse, furred tongue, and much restlessness. Mercury had been given by the mouth, and had also been rubbed in, and counter-irritation efficiently employed. On examining the chest, I found some dullness on the left side posteriorly, with muco-crepitant rhonchus, and over the chest generally some mucous rhonchi. Percussion was painful, and his decubitus was dorsal, leaning to the right side. He was cupped to zviii , and a large poultice applied to the chest. The mercury had but slightly, if at all, affected the gums, but was irritating the bowels. He was ordered a saline mixture, and a little Dover's powder night and morning. The following day we found him relieved, but there was more marked dullness below the angle of the left scapula, with bronchial breathing, and more small crepitation in the immediate vicinity. He was again cupped to zvj , and the poultices continued. Although his pain was greatly relieved, and he breathed without much difficulty, he had much restlessness, and passed wretched nights—the cough being troublesome, and the expectoration more or less pneumonic, but never copious. The dullness on percussion now rapidly extended, and soon occupied the whole of the left side, spreading quickly over the anterior of the chest. The bronchial respiration and augmented vocal resonance were, however, confined to the region about the angle of the left scapula. The sputa soon lost all trace of sanguineous admixture—were extremely moderate in quantity, and of a simple catarrhal character. The dullness gradually disappeared from the anterior of the chest, but continued in the lateral region and posteriorly. Respiration became everywhere audible, but laterally and posteriorly was feeble and distant. There was not much difference in the vocal fremitus of the two sides. His general condition improved, to a certain point, when he ceased to make progress—he was put out of breath on going up and down stairs to the carriage to take his ride, and his pulse continued quick and irritable, his tongue somewhat furred in the centre, but his appetite was moderately good, and he had absolutely no cough. He was annoyed by frequent examinations of the chest, repeatedly saying, "I am sure it is all right there"; and, "I am satisfied that you have effectively cured the inflammation"—"there is nothing in the world the matter with my chest," and so on. But on close questioning he would admit, that, especially in certain positions, he had a measure of discomfort or uneasiness about the situation of the angle of the scapula, and deep-seated. Being a man of great acquirements in almost every department of knowledge, he evinced his anatomical and medical knowledge by accounting for this uneasiness, which he attributed to adhesion, the result of the inflammation, etc. Although neither Mr. Solly nor myself were at all satisfied with his condition, yet

after waiting some weeks in vain, with the hope of finding his circulation become more tranquil, and the tongue and appetite improve, we agreed that change of air would probably do more for him than aught else. He accordingly went down to the sea-side, and bore the journey well.

Two days after his arrival at the sea-side, whilst dressing, he was suddenly seized with a violent fit of coughing, and vomited an enormous quantity of pus, by which he was well nigh suffocated, and made very faint. When seen by a medical gentleman in the neighbourhood, he was bathed in a profuse perspiration, pale, with a scarcely perceptible pulse, cold extremities, and still coughing violently, and bringing up large quantities of pus. The amount evacuated could not be accurately estimated, as much was, at the moment of seizure, lost on the floor; but from two to three pints, at least, must have been discharged within a few hours of the seizure. Wine and ammonia rallied him, but the cough continued all that day and night to a most distressing degree, and was attended by copious expectoration. The succeeding morning I had a telegraphic message to go to him immediately. I found him tranquil—breathing calmly, though rather quick—his countenance expressive of exhaustion, but not much anxiety—the skin sweating, and the pulse rapid, soft, and tolerably steady. He was able to take nutriment, and enjoyed both the beef-tea and claret wine which were allowed him. The cough, however, was constant and distressing, from the exhaustion which it occasioned, but was clearly the result merely of the effort of nature to complete the evacuation of pus, of which he continued to expectorate a considerable quantity. At this time, I did not think it desirable to make a more accurate examination of the chest than was necessary to satisfy myself that respiration was still to be heard, though rather faint and distant, throughout the affected side. Over the angle of the scapula it was, however, more tubular than when he left town. The succeeding morning I returned to town, and visited him again the following day. I then found him gradually recovering from the exhaustion. The expectoration was less, though still considerable, and the cough troublesome, interfering sadly with his rest. He was now ordered thirty minims of liquor cinchonæ, with a few drops of ipecacuan wine, three times a day, and nourishment and wine as before. No local measures were employed.

It is not necessary to continue the details of the case farther, for the recovery was steady and uninterrupted by the least untoward circumstance. In three weeks he was able to be removed to a warmer locality, in the immediate neighbourhood. As the cough and expectoration steadily diminished, he gained strength; the dullness of the side gradually cleared off; the natural amount of vocal fremitus returned; and, except over the angle of the scapula, the respiration became healthy. At the spot in question, however, there continued for some time to be a degree of preternatural vocal resonance, and the breathing was somewhat bronchial. In August he left England for Italy, where he spent the winter and spring. During the whole of the journey home, and for some time before, he was equal to as much physical exertion as ever, and had neither cough nor dyspnoea, even on climbing mountains. I had an opportunity of hastily examining his chest a few weeks after his return, and could detect no trace of his severe disease.

CASE II. FEVER WITH PLEURO-PNEUMONIA. EMPYEMA OPENING BY THE BRONCHI. RECOVERY. Edward Maroney, a labourer, *æt.* 35, was admitted into St. Thomas's Hospital, under my care, on the 15th April, 1851.

He had been ill five days with symptoms of fever, attended by some cough, coming on when he was still under the influence of mercury, or, at least, had very recently been so, having been treated with mercury and salivated in the Charing Cross Hospital, for inflammation of the eye. The tongue was much coated, his cough rather troublesome, the expectoration mucous, and there was little or no dyspnoea. He was ordered a purgative, and the catarrhal mixture of the

Hospital, containing a little antimony. On the 18th, he became worse; and on the 19th, he was complaining of very great pain of the chest, with quick and oppressed breathing. He had no more cough, but the expectoration was tenacious, sanguineous, prune-juice-like in appearance, intermixed with yellowish-green opaque matter. The great pain and tenderness of which he complained were referred chiefly to the supra-mammary region of the left side, where there was considerable dullness on percussion, ægophonic resonance of voice, and bronchial respiration, intermixed with muco-crepitant rhonchus. The pulse was quick and feeble, and the tongue was dry, but there was not much heat of skin. He was ordered to be cupped to ʒvj , and to have 4 grs. of Dover's powder, with 1 gr. of calomel, every four hours, with a draught containing ʒij of liquor ammoniæ acetatis and 3 grs. of sesquicarbonate of ammonia, in camphor mixture.

April 20th. He was relieved of his pain, 4 oz. only of blood having been taken by the cupping. A blister was ordered to the side. To continue the beef-tea allowed from the first.

April 21st. He had but little pain; pulse 104, feeble but steady; tongue and skin dry; some delirium. Over the antero-superior region of the left lung the breathing was bronchial, mixed with some crepitation; over the lateral region of the same side, there were general muco-crepitant rhonchi; the right lung was tolerably free; the expectoration was somewhat less copious, but very tenacious, and of a dirty greenish colour; bowels open. The head was ordered to be shaved, and the blister to be repeated.

April 23rd. The pulse had fallen to 96, the tongue was less dry, and the cough apparently looser, but the expectoration maintained the same character. He took his nourishment well; but rambled a little.

April 25th. The tongue and lips were covered with sordes, but the tongue was moist at the edges; the breathing was less frequent, and there was less muco-crepitant rhonchus in the left side; the cough and expectoration were less—the latter of the same character. He was directed to have ʒij of wine daily, and 4 grs. of sesquicarbonate of ammonia, with a drachm of tincture of squills, in decoction of senega, every six hours.

April 26th. Pulse 100, steady; there was dullness over the whole anterior region of left side, but coarse crepitation was everywhere heard. Tongue dry; bowels open; he had a better night, and considered himself improved. He was ordered to have ʒiv of wine, and lemonade for drink, as he complained of thirst.

April 28th. Dullness was very complete; nothing was to be heard but a loud soufflé on breathing, and whiffing resonance of voice; pulse 96, feeble; the tongue still dry; his support was taken well, and his cough less. After this date, blistering with liquor vesicatorius was frequently repeated.

May 2nd. The pulse had fallen to 88, the tongue was cleaning and moister, but the expectoration was still more or less sanguineous, and he again complained of pleuritic pain and tenderness in the left lateral region. This subsequently extended to the back, and he had afterwards a bronchial soufflé below the angle of the left scapula, with muffled resonance of voice and dullness, but with more or less surrounding muco-crepitant rhonchus. Soon after this, the expectoration lost its pneumonic character, and became trifling in quantity, and the general symptoms improved, when, without any material change in his general symptoms, he all at once began to cough much more, and the expectoration suddenly became profuse in quantity and purulent in character. For many weeks he continued to expectorate a large quantity of purulent and muco-purulent matter. The physical signs of effusion and compression of the lung gradually vanished; but for a long time there were traces of the former mischief about the angle of the left scapula, the respiration maintaining a bronchial character. He was kept in the Hospital simply for the sake of watching the progress of cure to its completion; and on the 16th of August he was carefully examined by some of my colleagues as well as by myself. We were unable to detect any evidence whatever of the severe and protracted disease

of which he had been the subject. The lung appeared, so far as could be ascertained by examination during life, to have completely recovered, nor was there any visible contraction of the chest.

CASE III. PLEURO-PNEUMO AND PNEUMOTHORAX. FATAL FROM CIRCUMSCRIBED EMPYEMA WITH GANGRENE OF LUNG. Edward Connor, æt. 32, came to London, from Ireland, a year ago. When a child, he had fever; and, eighteen months ago, an inflammatory attack of the character of pleurisy, for which he was blistered and confined to bed. With these exceptions, he had had good health. He stated that he had not been very well off, but that he never had indulged in spirits or beer. Eight days before admission, after exposure through a very cold and wet day, he was seized with pain of left side, and cough, attended by anorexia and thirst. To these symptoms succeeded dyspnoea, and some expectoration, for the last two or three days.

His decubitus, on admission, was dorsal, with the head raised; countenance somewhat flushed—not expressive of anxiety; skin not very hot or dry; pulse 90, soft. There was pain on motion or on coughing, which he referred to the sternum; the tongue was furred; the bowels open; respiration 32 per minute, performed without any apparent difficulty, nor did he complain of dyspnoea. The expectoration was copious; mixed in character, some frothy, some tenacious, and of the colour of prune-juice, and expectorated with tolerable facility. The chest, ample and well-formed, sounded well on percussion anteriorly. The respiratory murmur was everywhere heard, but mixed with more or less mucous and sonorous rhonchi, especially on the left side. The heart's action was natural. Posteriorly there was fair resonance on percussion throughout the right side, and the respiratory murmur was heard everywhere, mixed with some large mucous crepitation. Below the level of the spine of the scapula of the left side, there was some dullness, increasing towards the base of the lung, where, and in the inferior lateral region, there was complete dullness, and where percussion gave pain. Over the seat of dullness, there was a fine muco-crepitant rhonchus, and towards the spine the respiration had a slightly blowing character, but there was neither soufflé nor bronchophony. He was ordered low diet, with beef tea. \mathcal{R} Pulv. Doveri gr. viij; calomel. gr. ij; \mathcal{M} . Fiat pulv. horâ somni sumendus. He was directed to take an aperient draught in the morning, two tablespoonfuls of the catarrhal mixture every four hours, and five grains of Dover's powder with calomel every night; and to have a blister applied between the shoulders.

Feb. 26th. Being obliged from the blister to lie on the side, he preferred the right, pressure on the affected side giving him pain and inducing cough. He felt some nausea from the medicine. The expectoration was more copious, and more catarrhal in character, still, however, mixed with viscid reddish brown. Physical examination of the chest indicated that the inflammation had not extended; there were less of the bronchial rhonchi; and the patient expressed himself as more comfortable about the chest. Respirations 25; pulse 86, soft.

Feb. 28th. The blister was repeated.

March 1st. He breathed better; the dullness was less; respirations 22; pulse 88; tongue clean; he expectorated with ease.

March 3rd. Decubitus dorsal; there was tenderness on percussion over the left lateral region inferiorly; and over a spot of three fingers' breadth there was marked and circumscribed dullness on percussion, and the breathing was distant and somewhat blowing; the expectoration was less.

March 4th. Respirations 20; pulse 84.

March 6th. Cough troublesome; there was some increase of dullness over the false ribs of left side, and here as well as over the spot of circumscribed dullness, there was fine crepitation heard; around this, respiration was healthy. Pulse 88; respiration 22.

March 8th. He was improving in all respects; the expectoration had been for some days colourless.

March 11th. Expectoration was less copious, but very

offensive, and again coloured. He had pain, tenderness, and sense of constriction over the upper part of the chest; there was dullness on percussion beneath the clavicle, and in the left axilla. In these situations, and in the left lateral region generally, was more or less fine crepitation. Notwithstanding these symptoms, the pulse was 78; the appetite improved, and tongue clean; but the cough troublesome. He was ordered to have liquor vesicatorius applied to the side; to take the mixture every six hours; to have a pill composed of Dover's powder, extract of hyoscyamus, and squill pill, every night; and to have fish.

March 15th. Respiration was fairly natural in the dorsal and lateral regions inferiorly, but about the clavicle and in the axilla it was attended with muco-crepitant rhonchi, and augmented vocal fremitus. Pulse 80.

March 20th. There was some hæmoptysis; expectoration was muco-purulent. Pulse 96; skin hot; tongue rather red at the tip. He was directed to omit the former medicines, and to take, every six hours, an ounce of infusion of roses with sulphate of magnesia, and ten minims of tincture of digitalis; and a pill of Dover's powder and extract of hyoscyamus every night.

March 23rd. There was much febrile disturbance. He still expectorated some blood in clots. In the lower lateral region of the left side there was considerable dullness, associated with coarse mucous rhonchi, sometimes amounting to gurgling. Similar phenomena were manifested under the left clavicle. The expectoration was purulent and offensive. Respirations 36; pulse 80; bowels rather loose.

March 27th. There could be no doubt that in the left inferior lateral region there was considerable effusion, but limited to that region, and communicating with the lung; for there was now manifest bulging, with great dullness, and at one spot amphoric resonance and gurgling, the latter phenomena varying much from time to time. The expectoration was fetid and gangrenous in odour, and much more copious.

April 1st. In the localities last mentioned, *i. e.*, the left lower lateral region, and the infra-clavicular region of the same side, the phenomena maintained the same character, but in other parts of the same side much more respiration could be heard. From this date to the 24th, the auscultatory phenomena varied greatly from time to time, but clearly indicated the existence of cavities in the lungs, with pleuritic effusion, sometimes more and sometimes less, varying with the amount of expectoration; but the lower portion of the left side now presented a considerable swelling, and the liver was pushed down considerably below its proper level, the heart, however, maintaining its natural situation. Fluctuation in this swelling could be distinctly felt, and it was, therefore, determined to puncture it. This was done by Mr. Solly, with a lancet, between the seventh and eighth ribs, rather anterior to their middle, and a considerable quantity of thick, cheesy, stinking pus was evacuated. By this he was considerably relieved. His decubitus was at this time, and had been for some days, on the left side, avoiding pressure by resting on his elbow. On the 26th, his respiration was comparatively easy, his cough less, and he was free from pain, and the opening discharged freely. There was dullness on percussion from below the second rib anteriorly, but respiration was heard, though bronchial in character, and mixed with mucous gurgling; pulse 100, small.

May 1st. Respiration, more or less distinct, might be heard throughout the left side posteriorly and laterally.

May 8th. He appeared to be gaining strength; to the left, and a little below the left nipple, under the edge of the pectoral muscle, there was loud amphoric breathing, with metallic or amphoric resonance on percussion; with the exception of this locality, the respiration might be everywhere else heard, of tolerably fair character.

May 29th. He had lost ground considerably. Posteriorly, respiration was generally heard. Anteriorly below, and on a level with the edge of the pectoral muscle, there was amphoric resonance and pectoriloquy. More towards the sternum, there were mucous rhonchi and some dullness; there was general flattening of the left side. The prominence, where the puncture had been made, had entirely disap-

peared, and the opening had closed; cough and expectoration had increased; breathing was tranquil.

June 5th. The side reopened spontaneously, and again discharged, but the expectoration was more profuse; the pulse was small and rapid, and powers failing; the matter discharged from the side was much less offensive than that expectorated from the mouth.

June 7th. He became suddenly worse; collapse was extreme; respiration very hurried; he was delirious; the expectoration of stinking pus was profuse. In the evening he died.

June 8th. POST-MORTEM EXAMINATION, at half-past eleven A.M., obtained with difficulty, and chest only examined. The heart was found to be somewhat displaced towards the left side, the right lung being somewhat expanded, and the left diminished. The anterior surface of the left ventricle of the heart presented two or three patches of adhesions, not of very old date. The pericardium contained a very small quantity of clear serum, and the heart itself was healthy. The right pleura was healthy, and the corresponding lung voluminous, crepitant throughout, and somewhat emphysematous. The bronchial tubes, though not apparently congested, contained a considerable quantity of tenacious muco-purulent fluid. The left pleura was almost universally adherent, by tough but not very old adhesions. The only portion not so occupied, was a space of about nine square inches, situated between the seventh and eighth ribs, just external to the cartilages. The parietes of the cavity which existed at this part, were of a greenish colour, soft, and shreddy. The cavity contained a small quantity of dirty fetid pus, and communicated by two or three ragged openings, capable of admitting a finger between the sixth and seventh ribs, with a second cavity formed between the integuments and the ribs. The upper surface of the seventh rib was denuded and carious. Between the seventh and eighth ribs there was a small opening communicating with the exterior, which had been made by the trocar during life, and this cavity communicated also with the lung by a small ulcerated opening. The anterior half of the upper lobe of the left lung, and the anterior corner of the lower lobe, presented numerous large anfractuons intercommunicating cavities, the lowest one being apparently formed by both lobes. These cavities contained a quantity of dirty, stinking pus, with here and there shreds of gangrenous tissue. Their parietes were irregular and reticulated, though to a certain degree smooth and polished, owing to the formation of a lining membrane, and they were evidently in process of cure. The walls of these cavities which were lowest in position, were somewhat congested, and less perfectly furnished with a lining membrane than the others. In other parts of the base of the lung there were also several small cavities filled with flocculent, gangrenous matter, the sides of which were also flocculent and gangrenous. The whole series of cavities evidently communicated with one another, and with the cavity in the pleura. There were some patches of solid lung-structure, situated chiefly in the vicinity of the cavities, but the remainder, the great bulk of the lung, was crepitant.

CASE IV. PLEURITIS. EMPYEMA OPENING INTO THE BRONCHI. RECOVERY. A tradesman, æt. 56, of healthy constitution, and very temperate, regular habits, seven weeks previously to being seen by me, was suddenly seized with severe pain of the left side and of the left hypochondrium, attended by some cough and fever. He was seen early by Mr. E. Pye Smith, by whom he was bled, cupped, and blistered, and placed under the influence of mercury. The side became rapidly and perfectly dull on percussion, with absence of respiratory murmur. There was a little mucous crepitation to be heard posteriorly at one time, and slight mucous expectoration existed for a few days; but there never was much cough, nor any sanguineous tinging of the expectoration. The pain and febrile action subsided satisfactorily; but, despite counter-irritation, mercury and other remedies, the side remained dull on percussion, and there was no return of respiratory murmur.

When seen by me on 24th Nov., the pulse was soft and under 80, the skin of natural temperature and moisture, the countenance not expressive of any anxiety; he had no cough, was free from pain; could lie on either side, but preferred lying on the back; the tongue was rather coated and furred in the centre, but moist; the appetite moderately good. On examination, I found the left side of the chest rounder and apparently larger than the right, the intercostal spaces obliterated, and there was very little motion of the ribs. No vocal fremitus could be felt. The whole side was perfectly dull on percussion, except over the apex of the lung, and even there the resonance was much less than on the opposite side. No respiratory murmur could be heard, except beneath the clavicle and in the corresponding supra-spinous region, where it was harsh and somewhat tubular in character. I could not detect any mucous rhonchus, or crepitation, or friction sound, nor was there any increased vocal resonance anywhere, nor any bronchial respiration except at the root of the lung. The heart appeared to be in its natural situation, and change of position did not give rise to any material change in the auscultatory phenomena. The breathing was calm, not much increased in frequency, and the exertion attendant on the examination did not induce any dyspnoea. If, however, he walked about his room he was conscious of being short-breathed. There was not, and had not been, anything like hectic; but his nights had sometimes been restless, and he was frequently very uncomfortable, and did not sleep well.

I gave it as my opinion that the case was one of empyema, and not of consolidated lung; and from the entire absence of any urgent symptoms, either local or general, I advised that we should wait and watch the case for a while longer before making any proposal to puncture the chest; and that he should take a pill night and morning, containing two grains of blue pill and four of Dover's powder, and a draught three times a-day, containing hydriodate of potash, tincture of squills, and spirit of nitrous ether, in decoction of sarsaparilla. A large blister was ordered to be applied to the side, and a more stimulating nourishing diet allowed.

Dec. 1st. I again saw him, and found that three days previously he had had a sudden but not severe fit of coughing, and had expectorated a small quantity of dark-coloured extremely foetid pus. This was followed by more copious expectoration, less foetid, but distinctly purulent, amounting to 8 or 10 oz. in the twenty-four hours. The general symptoms were much the same as when I first saw him, but the tongue was cleaner; he had not been so restless, and had lost the ill-defined sense of discomfort or *malaise*. But the state of the chest had materially changed. The round appearance was gone, the intercostal sulci were distinct and well-marked; still, however, the side was dull on percussion throughout, although there was a considerable improvement in the antero-superior region. In the whole of this region, and through a considerable space posteriorly, faint and distant respiratory sounds could now be detected during deep inspiration, and here and there occasional mucous rhonchi were heard. There was, however, no vocal fremitus, or vocal resonance, nor any blowing respiration.

Dec. 10th. He has continued to improve in all respects, and everything leads to the conclusion that a speedy and complete cure will be effected.

Another case of pleuro-pneumonia, ending in empyema, was in the same ward, under my care, at the same time with Connor. The subject was a young man who had had previous attacks of an inflammatory character, and who was admitted into one of the surgical wards, as it was supposed that he had received an injury to the side. This, however, was not the case; and he was soon perceived to be the subject of acute pneumonia, and came under my care. The pneumonia was extensive and severe; it was situated in the right lung, and was attended by great orthopnoea, cough, and pain. As the pneumonic symptoms subsided, his chest became distended by fluid, and the signs of empyema were well pronounced. The accumulation increasing, he was urgently advised to submit to paracentesis. This he refused to do,

and left the hospital, with the right pleura enormously distended. He then fell under the care of Dr. Aldis, suffering from all the effects of compression of the lung from pleuritic effusion. He was supposed by Dr. Aldis to be dying; but not long after again made his appearance, greatly improved, and able to walk a considerable distance. From the intermediate history and the examination that was again made of the chest, Dr. Aldis had no doubt that the pleuritic effusion had been evacuated through the bronchi.

REMARKS. The cases which have been detailed very well illustrate, I think, the general character of the inflammatory disease which has prevailed to a considerable extent within the last eighteen months or more. The particular termination of these cases, by discharge of the purulent accumulation through the bronchi, is probably the least frequent, and I have merely selected such cases from their offering additional points of interest. I might have selected from my records of both private and public practice, other cases presenting the same general characters, in so far as regards the type of inflammatory action, and the course they ran.

The attention of most observers must have been more or less arrested by the modifications which our treatment of local inflammation, and especially of pneumonia, has for some years been undergoing, especially in reference to the employment of bleeding. In this important remedy the faith of many has been utterly shaken; nor has it fared better with antimony and mercury, in which many have been wont to place the most unlimited confidence. The dicta of Louis, in reference to the inefficacy of bleeding, except in the very earliest period of pneumonia, have not indeed been received in this country with unquestioning consent: but neither has the non-correspondence of his experience with that of British practitioners been satisfactorily explained. It cannot, I think, be doubted that, apart from varieties in what is called the epidemic constitution, there are important differences in the same disease, in so far as regards the constitutional symptoms by which it is manifested, dependent, perhaps, on climate, national constitutions, habits, modes of life, etc., as well as differences dependent on varieties of individual constitutions. All this, it may be said, is known and admitted; but is it sufficiently considered in practice? Is it sufficiently borne in mind, in estimating the statements and experience of observers, situated in very different circumstances from our own? I am satisfied that much of the contrariety existing between French and British practitioners in reference to some of the more ordinary diseases, and the more common points of practice, is explicable by such considerations and by such alone. Thus, when going round the wards of the *Hôtel Dieu* last summer, with M. Louis, I observed several cases of erysipelas, and asked whether he found it necessary to employ stimuli to any extent in their treatment. I was struck by his answer, that he did not find it necessary to employ any treatment beyond rest and the most simple dietetic rules; for that in his experience idiopathic erysipelas was a very trifling disease, and never fatal, unless associated with some visceral disease or cachectic habit. Now this certainly is not the experience of our British hospitals; at all events, not of the London hospitals. Nor is it the experience of private practitioners in this country. It is true that the majority of cases of idiopathic erysipelas do well, and that the disease manifests a strong natural tendency to cure, after running a specific course. But with us it is by no means a trifling ailment—it is essentially of an adynamic type, and requires a tonic treatment; more decided and vigorous, it may be, in some cases than in others. But whilst it is manifestly necessary to exercise much caution ere we adopt or reject the results of the experience of other observers, whether of our own or any other country, scarcely less caution is requisite either in following or discarding our own so-called experience. It appears to me that we are by no means warranted in inferring that, because bleeding and antimony are not found to answer so well in the treat-

ment of pneumonia as we had been taught to believe, or as we formerly found them to do, therefore our former experience, or that of our predecessors, was fallacious. These remedies will, I believe, be found fully to warrant the confidence that was placed in them, when they are judiciously employed in the treatment of the same type of disease. We must, however, be sure that the same phenomena are present which former observers have pointed out as the indications for blood-letting. We are not justified in questioning the correctness of their therapeutic precepts, unless we have applied them and found them wanting, not merely in what we believe to be the same disease, pathologically speaking, but in the same disease attended by those phenomena which they depicted in no obscure or doubtful manner. Most unnecessary and unmerited discredit is thrown on our science, and especially on our art, therapeutics, by thus questioning or discarding the results of former experience, merely because they are not available for our present necessities. The arch enemy, the spirit of quackery, is ever ready to turn to good account, for his own purposes, such error. And still greater is the advantage given him, when from over-weening confidence in established remedies, or inability to discover "the signs of the times" in reference to disease, there are found those who obstinately persist in the attempt to make disease accord with their treatment, rather than change their treatment with the disease. Doubtless, much of what is called experience, is fallacious, and we ought not, from unworthy fears of bringing discredit on our art, to shrink from abandoning error when once proved to be error. There has been no little craft displayed by the globulists in the selection of those acute diseases which they have made their stalking horse; and nothing is more easy than the attempt to turn to the discredit of legitimate medicine, the difference of treatment pursued in diseases called by the same name.

True sthenic pneumonia of the croupous variety, *i. e.*, inflammation attacking the air cells, and characterised by the effusion of plastic matter, by which these are obliterated, and which leads to solidification of the lung, when on being cut into, presents the characteristic granular surface, arising from the filling of the cells with solid lymph, has become a comparatively rare disease of late. The ordinary received descriptions of this disease are, however, true to nature; and there would not, perhaps, on close examination, be found to be much difference of opinion among experienced judicious practitioners, as to the treatment of such disease. For my own part, in proportion as I found a given case of such disease to correspond in its constitutional phenomena with those which the writers of the time of Cullen, and even much subsequently, described as indicating the necessity for blood-letting, I should with them consider it as the "*remedium magnum*", and employ it with as much confidence as they did. The pleuritis which accompanies this form of pneumonia is, for the most part, attended simply by the effusion of plastic matter, adhering to the two sides of the serous membrane, and unassociated with much fluid. And the pleuritis itself is quite a subsidiary and secondary disease, the mere result of the extension of the inflammation from its contiguous seat in the lung itself. The pleuro-pneumonia thus constituted, partakes of the same general character as the simple pneumonia.

In all these, as well as in other important respects, the inflammatory disease which has of late prevailed, and of which I have detailed several examples, differs considerably. It differs both in the character of the attendant constitutional symptoms, of the structural changes, and the treatment demanded. It is not, however, what has been generally understood as typhoid pneumonia. Certainly it is not always, nor generally, associated with either typhus or typhoid fever. It is, for the most part, unaccompanied either with any specific form of eruption, or evidence of contagion. In many instances the pleuritis has been the earliest of the two affections, in the order of occurrence, and in most, the more prominent affection. In some cases the disease has begun with catarrhal symptoms, subsequently passing into pneumonia or broncho-pneumonia, concurrent with the su-

pervention of pleurisy. The pain has been frequently great, and a very prominent symptom; and effusion has taken place rapidly and to a great extent, assuming, I think, very early a purulent character. Cough has not been either a troublesome or prominent symptom. The sputum at some period, sometimes earlier and sometimes later, has almost always indicated that the substance of the lung and the air-cells were involved in the inflammatory action. It has not indeed presented the ordinary characters of the brick-dust or rusty sputum of the sthenic pneumonia, expectorated in small masses of extreme viscosity; but it has always been more or less tenacious and glairy, sometimes streaked with blood, and at other times presenting the appearance of prune juice, or of a dirty greenish-yellow colour, and copious in quantity. It has varied also in the same case from day to day—at one time being free from sanguineous impregnation, having the appearance of simple viscid bronchial secretion, and the next day, perhaps, being more of a bistre colour. The dyspnoea has not usually been urgent, nor the respiration at all laboured, but for the most part of increased frequency. In most cases the skin and tongue have been moist, the former clammy, and the latter loaded with a dirty creamy fur—sometimes, however, dry and brown. The pulse, generally rapid, has usually been soft, sometimes very feeble—the urine, sometimes high coloured and scanty, in other cases has been copious and of a pale straw colour. In short, the constitutional symptoms have not been those indicative of excited action of the vascular system: so far from it, that, judging by the skin and pulse alone, it might frequently be inferred that little or no fever was present. I have seen in some instances, even where the greater portion of one lung was manifestly involved in the inflammatory action, but little if any appreciable excitement of pulse or difficulty of respiration.

The physical signs have shown that the inflammatory action has spread rapidly over a large extent of surface, although generally confined to one side. It is also deserving of special attention, that the upper lobes are much more frequently implicated than is observed in the ordinary sthenic pneumonia. The amount of solidification of the lung that ultimately results, is not, however, always correspondingly great, or, at all events, is not very complete; nor is it so permanent; that is, the lung sooner returns to a condition in which it is more or less permeable to air. It has appeared to me to be checked in a measure by the pleuritic effusion as this becomes copious; the ordinary result of copious pleuritic effusions ensuing—compression rather than enlargement and solidification from effusion of solid matter in the substance of the lung. Where the amount of pleural effusion has been less, and the pneumonitis has pursued its own course, uninfluenced by external pressure, suppurative infiltration of the lung has often supervened, without much complete preceding solidification. This state of lung, as was manifest in the case of Maroney, shows a tendency to gangrenous destruction: and one of the chief points of interest in the *post-mortem* history of Maroney's case, is the small amount of solidification that was found, notwithstanding the extent of lung involved. It was only in the immediate vicinity of the gangrenous cavities that the lung was impervious to air and non-crepitant. Indeed, it seemed pretty clear that the case proved fatal, not so much from the extent of lung originally involved in the inflammatory action, as from its character and the consequent gangrene. The suppurative tendency is still more marked in the pleural cavity. This tendency to suppuration, breaking down, and gangrene of the tissues, probably accounts for the particular termination of the cases detailed; at least, in two of them. In the case of the gentleman first detailed, I believe, the principal accumulation of pus was interlobar, and that, as the acute stage subsided, the effusion in the general cavity of the pleura was, for the most part, absorbed; whilst a considerable collection still remained pent up between the lobes of the lung and its root; so that, when, at length, the matter obtained exit, the outlet was very direct, opening immediately, or nearly so, into the larger bronchial trunks. Thus,

the discharge was sudden, rapid, effectual, and uninterrupted till the whole was expectorated. The sides of the cavity would thus be brought more readily into apposition, and its obliteration effected. The steady, rapid progress towards cure of this case, after the discharge of the matter, independently of the physical indications, shows, I think, how little true solidification of lung there had been.

The absence of the signs of pneumothorax (except in the case of Connor, where the indications of a circumscribed pneumothorax were well marked) is a point of great interest in all the cases detailed. This circumstance may perhaps excite doubts in the minds of some, whether there were really any communication with the bronchi. But I know not in what other way we are to explain the sudden removal of the pleuritic effusion, and the circumstances attending that removal. In the first case detailed, there cannot be the least doubt that a very large accumulation of fluid obtained sudden exit by the bronchi, so as for a time to place the life of the patient in extreme jeopardy. In the last case, the sudden discharge of a small quantity of foetid, gangrenous matter, succeeded by more copious purulent expectoration, was immediately followed by marked changes in the physical signs, which indicated the rapid disappearance of an accumulation of fluid in the pleura. Whether, in this and the other cases, the absence of all signs of the presence of air in the pleural cavity, is to be ascribed to the existence of extensive adhesions, or to any peculiarities of the communication with the bronchi, I am unable to say.

Such are the more important features of the thoracic inflammation, to which I venture to call the attention of the profession; and they are sufficient, I think, to show that it differs, in many most material respects, from the ordinary form of either pneumonia or pleuritis. Upon what does this difference depend? Not, I think, merely on peculiarities of individual constitutions. I have seen the disease in various constitutions, and in persons moving in very different social spheres. It has no necessary connexion with any form of continued fever. Is it connected with erysipelas? I am disposed to think that it is: not that it is generally associated with the external manifestation of erysipelas. The pneumonia that is associated with fever, erysipelas, and cachectic states of system generally, it is well known, is usually of the asthenic type; but I am disposed to regard the pleuro-pneumonia now under discussion as itself a form of erysipelatous disease, and for these, among other reasons: 1st. In its pathological features, it closely resembles erysipelatous inflammation; 2nd. It has prevailed contemporaneously with external erysipelas; 3rd. An erysipelatous form of cyanosis has been very common, and, in many cases, has been an attendant on the thoracic inflammation; sore throat having been frequently complained of in the beginning, and, as this has subsided, bronchial symptoms have occurred, to which the pneumonia and pleuritis have succeeded. I feel, however, bound to admit that it differs in some material respects from the ordinary forms under which erysipelatous inflammation of internal organs has hitherto been known to us.

In respect of the treatment of this disease, it is manifest that it must differ materially from that of the ordinary forms either of pneumonia or pleuritis. General bleeding is rarely if ever admissible: I have never employed it. Local depletion, to a limited extent, especially in the early stages, is sometimes decidedly useful, especially from the relief it affords to the pain and the congested state of the parts implicated. Counter-irritation may be more early employed than is desirable in the more asthenic forms. Blisters, indeed, I have found of the most marked benefit, and have been in the habit of repeating them frequently. Calomel and antimony, if used at all, must be very cautiously and sparingly employed. Dover's powder, in doses of five grains, with a grain of calomel, three or four times a day, has appeared to me very useful. But I have not given the calomel with the view of affecting the system, so as to induce any of the symptoms of mercurialisation. Ammonia has proved the best expectorant; and this I have given usually with the acetate of ammonia, sometimes with the

camphor mixture, and at other times with serpentary or senega. In almost all cases, I have allowed the patients beef-tea, and very frequently found a certain portion of wine to be necessary. But, under any plan of treatment, the affection is attended by great danger, and, in its worst forms, very fatal. So rapid has been the progress in many cases, so great the prostration, even with the most cautious treatment, that I have, in more than one case been led to doubt whether the patient would not have had a better prospect by entire abstinence from all antiphlogistic treatment, so called, and the use of stimuli alone *ab initio*. Ample and efficient blisters, with wine, beef-tea, and ammonia, are, I believe, the remedies on which most reliance should be placed in the most aggravated and most characteristic examples of the disease. But such remedies must be used cautiously. Many cases will do well with little or no treatment, even though, as ascertained by the physical signs, there be a considerable amount of inflammation; a simple diet, not too antiphlogistic, rest, and an open state of the bowels, with some counter-irritation, being all that are requisite; anything beyond this, like the homœopathic globules, serving only to amuse the patient, and gain for physic a degree of credit which is not its due.

Since writing the preceding observations, the substance of which was read before the Medical Society of London on the 16th Oct., I have been not a little gratified by finding how much they coincide with those made by my honoured preceptor, Dr. Alison, in the November number of the *Edinburgh Monthly Journal*. I cannot but feel additional confidence in the accuracy of my own observations, when thus confirmed, and I have the less hesitation in pressing on the attention of the profession the views here set forth. But, how long the present type of pneumonia may continue to prevail cannot be predicted, and we must not therefore repeat the errors on which we have ventured to comment, but recall the words of our own Hippocrates. "Hoc saltem pro comperto habeo ex multiplici accuratissimarum observationum fide, prædictas morborum species, præsertim febres continuas, ita toto celo differre, ut, qua methodo currente anno ægrotos liberaveris, eadem ipsa anno jam vertente forsitan e medio tolles; quodque, ubi semel in genuinam medendi rationem, quam hæc vel illa febris species sibi vendicat, auspicio inciderim, ad eundem scopum collimans (favente, ut fit, Optimo Numine), metam quasi semper attingam, respectu ad temperamentum, ætatem, et reliqua ejusmodi usquequaque habito; donec, extincta illa specie novoque gliscente malo, anceps rursus hæreo qua mihi via insistendum ut ægris subveniam; ac proinde, nisi ingenti adhibita cautela intentisque omnibus animi nervis, vix ac ne vix quidem possum efficere ne unus aut alter eorum qui se primi meæ curæ commiserint, vita periclitetur; donec, investigato jugiter tandemque perspecto morbi genio, ad eundem perdomandum recto pede et intrepidus denuo procedam." (Sydenham, *Observat. Medic.*, sect. 1, cap. II, p. 29. Sydenham Society's Edition.)

15 Finsbury Square, 18th Dec. 1852.

MECHANICAL SUPPORT IN PROLAPSUS ANI.

By JAMES DEANE, Esq., M.R.C.S.Eng.

It is singular that we hear so little of mechanical support in cases of prolapsus ani. Authors will puzzle us with minute and unpractical distinctions about the first element in different cases of hæmorrhoids, and will then forget that, whether it be their cause or not, the prolapsus, so generally accompanying them, will always aggravate them, and even form fresh piles, however carefully an excision may have been effected. Their treatment, also, has been well discussed; but have we been as attentive to their prevention? Have any means been devised for supporting the perineum during the expulsion of the fæces? What else can remedy

the relaxed state of the levatores ani? and, if constantly supported during the evacuation of the rectum, what more reasonable than to suppose that the hæmorrhoids will yield to some mild treatment? or, if requiring removal, that their re-formation will be prevented?

Such was the train of reasoning that occurred to me in the after-treatment of the following case.

CASE. A. B., aged 25, had suffered from prolapsus for sixteen years. During that time, the bowel had descended invariably with each act of defæcation. On examination, I found external piles, large and numerous, and a loose fold of integument completely encircling the anus, and projecting about three-eighths of an inch. I found also internal piles, two in number, about half the size of a filbert, and a general abnormal rugosity of the mucous membrane, the nidus of future hæmorrhoids in the present state of parts. She suffered great pain at stool, and the fæces were generally more or less marked with blood. Her general health was very delicate: she had a pale, exsanguined appearance. I removed the external piles by incision, and the loose fold of (skin?) projecting from and encircling the anus. This was, no doubt, originally mucous membrane, which had been protruded, and had taken the form of skin from atmospheric exposure. The wound soon healed, but the prolapsus was as bad as ever, and, if not remedied (the parts being protruded and strangulated for a time daily), would soon have brought on fresh piles, and my patient would soon have receded into her former state.

What was to be done? Here the records of surgery give us no information. I adopted the following plan, with the utmost possible success. My patient has now used it for upwards of two years, and has not during that time had the bowel down, except when accidentally requiring an evacuation when from home. This occasional exception, so certain when the board was not used, distinctly proves that the non-prolapsus, at other times, was due to the contrivance, as truly as the non-descent of the bowel is due to a truss. It is probable that the analogy may go further, and that the *absolute constancy* of this support during defæcation will *cure* prolapsus, just as a truss cures hernia, when used for years without the permission of one descent of the bowel. I may also add, that, since the use of the board, I have heard no more in this case of piles, either internal or external.

The plan may be described thus:—Cover a chamber utensil with a strong flat board, taking a circular form, and projecting one inch; let into the edge of the wood three or four pieces of wood, to keep it fixed on the chamber-pot; make an opening on the surface of the board, a little behind its centre, just large enough for the anus to act; and surround this opening with an elevated ridge, to support the entire perineum and sides of the anus during evacuation. The anal foramen which I have used, has been oval, its long diameter being antero-posterior, and four inches in length, and its transverse diameter being two inches and a half. It has been abrupt, not bevelled; the sharpness of the edge being removed. The ridge has been half an inch high, and has extended all round the anal foramen, and has been less than half an inch from it. The great object is to keep it within the ischia. Some of my patients have felt more secure and more comfortable *with*, and some *without* this ridge. For females, I have had a large anterior urinary fissure, half an inch wide towards the middle of the board, and opening into the foramen, and gradually enlarging forwards to the size of three inches in front. With males, I have recommended another utensil in front.

As "there is nothing new under the sun", some such apparatus may possibly have been already used without my knowledge; and I have no doubt that, if the attention of the profession be directed to the subject of this paper, some better plan may be discovered than that which I have suggested.

Chatteris, Cambridgeshire, Dec. 10th, 1852.

AMPUTATION OF THE ARM IMMEDIATELY BELOW THE SHOULDER JOINT, FOLLOWED BY RECOVERY, IN A CHILD AGED FIFTEEN MONTHS.

By ROBERT EDWARDS JONES, M.R.C.S.

On the sixth of September, in consequence of the absence of Mr. Mason, of Sudbury, I was hastily summoned to visit Eliza Harrington, aged 15 months, the child of poor parents, residing at Wickham St. Paul's, Essex, who had been knocked down by a waggon, the wheel of which had passed over her left arm. On examination, I found a fracture of the humerus at its lower third, the bone protruding denuded of its integuments, and the soft parts lacerated nearly to the shoulder joint: the little patient was much exhausted from loss of blood. I administered small quantities of brandy and water, which had the effect of producing reaction; and feeling there was no time to be lost, I at once amputated just below the shoulder-joint, being just able to save sufficient integument to form a good stump. I was ably assisted by Mr. Mason, jun., and very little blood was lost during the operation, and but one artery required a ligature. The child had severe convulsions the following day, which were relieved by small doses of tincture of opii; after which it progressed most favourably, and at the end of a month had perfectly recovered.

I am induced to send this case for publication, because I believe that it is rare for a child of such a tender age to recover from so severe a proceeding.

Long Melford, Suffolk, Nov. 1852.

FATAL DISEASES OF THE STOMACH.

By JOHN CHARLES HALL, M.D., Fellow of the Royal College of Physicians of Edinburgh, etc.

THE most important truths may be derived from a faithful record of those cases in which, notwithstanding all our efforts, the disease we are called upon to treat proves fatal. However pleasing and flattering to our vanity it may be, to publish those cases only in which we have been successful,—fatal cases, at least, as much as those which have had a favourable termination, convey important lessons.

CASE 1. On November 1st, 1852, I was requested to see, in consultation with my friend, Mr. Henry Julian Hunter, surgeon, Mr. F——, of Sheffield, aged 46, a brass-turner. From Mr. Hunter I learnt that he became his patient on the 20th of May, 1852, with symptoms of dyspepsia, under which he had then laboured for some time. He prescribed mild laxatives, with infusion of calumba, and prussic acid, and, on the 25th of May, the nitrate of bismuth and rhubarb. Under this plan of treatment, and a mild diet, the patient became much better. Mr. Hunter did not see him again until the 27th of August, when he called upon him, having, meantime, been under the care of Dr. ———, who had ordered him to be rubbed with the linimentum hydrargyri, etc. He had also been to Dr. M——, a physician, residing some distance from Sheffield, who prescribed calomel and the compound powder of antimony, and a simple saline mixture. He had now the same symptoms as when last attended by Mr. Hunter, and the same plan of treatment was again adopted.

Sept. 19th. He was much worse; had obstinate constipation; almost constant vomiting; and severe pain in the region of the stomach. Small doses of castor oil, and clysters of warm water, were given. An ointment of tartarised antimony was applied over the region of the stomach, which gave some little relief. He continued much the same until Oct. 7th, when all the symptoms were aggravated; the pain and sickness were constant, and the food rejected almost as soon as taken. Sometimes, however, it remained some hours, and was then vomited. The bowels were kept open with clysters; leeches, and a plaster of belladonna, were applied to the epigastrium.

Oct. 8th to 10th. First, prussic acid and water, then creasote and water, were prescribed; but the pain still continued, and even a little milk was vomited a few minutes after it was swallowed.

Oct. 10th. Mr. Hunter tried the nitrate of silver with opium, with some little advantage; but the symptoms again returned with increased severity, and so continued to the day when we met in consultation.

Nov. 1st. The first thing that struck me was the shrunk appearance of Mr. F—. I had not seen him for nearly two years, when attending another member of his family. He was then very fat, and appeared to be in good health. This wasted appearance at once impressed my mind unfavourably; for I have found, in the cases of this kind I have seen, that emaciation is a very ugly circumstance, and affords strong presumption that the long-continued pain and sickness are caused by organic disease of the stomach.

He told us, that for more than a year he had felt a constant uneasiness over his stomach, and that now and then during that period he had had severe pain; that on these occasions he was sick; after which the stomach did not feel so full, and he was better, often for days together. This appeared to have been the case, from Mr. Hunter's prescribing for him, on the 25th of May, to the end of August, when Mr. F— again consulted him. He had for many years past partaken freely of spirits and ale, but more ale than anything else.

When we entered the room, he was in violent pain, having just thrown up some milk, which was shown to us. He said that the pain was constant, that he was sick every two or three hours, and could get no rest. His face had a yellowish green aspect, and looked more like *wax* than *flesh*. The pulse was 80; the tongue clean and moist; the urine natural. The organs within the chest appeared healthy. The liver was evidently much enlarged. The abdomen was generally flat, and had the appearance of being drawn inwards; *pressure over the stomach gave no pain*; and the most careful examination did not enable either Mr. Hunter or myself to detect any hardness of or tumour near the pylorus.

Mr. Hunter had noted the case as one of disease of the pylorus, an opinion of the correctness of which there could be no doubt.

It was agreed in consultation to give a teaspoonful of water, with one drop of prussic acid (*Scheele's*), every two or three hours; and to confine the diet to a teaspoonful of milk, thickened with arrow-root. The bowels, which had been confined for a day or two, were relieved with a clyster, and the strength of the patient was ordered to be supported with injections of strong beef-tea. A blister was applied over the stomach.

Nov. 7th and 8th. He appeared better; was only sick twice in twenty-four hours; but at times had been in great agony.

Nov. 10th. He had been again very sick, and complained of *almost constant* pain. The countenance had a pinched and anxious appearance, and the peculiar yellowish-green hue, so characteristic of organic disease of the viscera, was more marked. We were shown some dark, grumous, offensive fluid, which he had vomited, evidently containing a considerable portion of blood.

The pulse was quick, and very feeble. Everything was now ejected, even a little cold water. In a case I had seen some time ago, in Nottinghamshire, with Mr. Nelson, chloroform had, for several weeks, given the greatest relief; the vomiting appearing to be checked by it, and the pain to be relieved, although only for a time; the patient, a female, in the end, dying from cancer of the stomach. At my suggestion, therefore, three drops of chloroform were given in a little water; but the patient disliked the smell, and refused to take it.

He was ordered to take nothing but a little ice, and to let it melt in his mouth. Beef-tea injections, etc., to sustain life; morphia, opiate injections, a plaster of belladonna, and opium, etc., were suggested, in order to give what temporary relief from suffering we could, but, I fear, with

little success; the pain and sickness continued, and he died from exhaustion on the 16th of November.

Post-mortem examination, 36 hours after death. The body was much emaciated; the organs within the chest were healthy. The omentum was not thicker than a piece of paper. The liver was much enlarged from hypertrophy of the white substance (*nutmeg* liver); the gall-bladder contained a small quantity of bile; the pancreas, spleen, and kidneys, were healthy; as was also the alimentary canal below the stomach. The stomach* was enlarged, and behind the lesser curvature there was a mass of scirrhus glands. On opening the stomach, below the cardiac orifice, we observed a *large and very bright vermillion patch* on the mucous membrane, several inches in extent, and shaded into a grey colour, as it passed towards the pylorus. Below the sphincter of the pylorus, was a large cancerous ulcer. To borrow the words of a gentleman present at the examination, as highly characteristic, the edges had a "punched appearance". The ulcer had destroyed all the coats of the stomach, the contents of which were only retained by the adjacent peritoneum, which had evidently become united during the progress of the disease; and even this was so softened, that it gave way in removing the stomach from the body. The pylorus was surrounded by and involved in a mass of disease of the same nature, by which the natural outlet was reduced to a very small size. The mucous membrane, *softened throughout*, could easily be separated. The stomach was empty.

REMARKS. It will, perhaps, be better to direct the few observations I have to make on this very interesting case, 1stly, to the symptoms present during life; 2ndly, to the post-mortem appearances; 3rdly, to the treatment of similar cases.

1. SYMPTOMS DURING LIFE. This case well illustrates the fact, first, I believe, pointed out by M. Andral, in his work on Clinical Medicine, that, in the early stages of disease of the pylorus, causing this opening to be narrowed, there is generally copious vomiting every eight or ten days, or even more frequently, by which the sufferings of the patient are much relieved; the distended stomach disgorging its contents. The late Dr. Hope† has remarked, that when the contraction has proceeded from carcinomatous tumours, "*the vomiting ceases when the ulceration of the tumour leaves the orifice free*"; but the symptom "*recurs in proportion as the tumour is regenerated*"; still, it occasionally happens, that similar dilatation of the stomach takes place when the pyloric orifice is enlarged—an anomaly which arises from the thickened walls of the viscus having lost their tonic contractile power, whence accumulations arise as in an inert bag.‡ M. Andral,§ Dr. Seymour,|| Dr. Watson,¶ and others, have directed attention to the peculiarity of the symptoms characteristic of cancer of the stomach; but sometimes there is not one symptom by which it can be detected by the most experienced and skilful practitioner. Some patients have much pain—others have none at all; one patient vomits continually—another patient, from the commencement to the termination

* The body was examined by Mr. Hunter, in my presence; the stomach was removed to the Sheffield Medical Institution, and examined by Messrs. Allanson and Atkin (lecturers on anatomy), Mr. Parker, and Dr. Elam. The preparation (with remarks on the case) was shown by me to the members of the Sheffield Medical Society, Dec. 2nd, 1852.

† Morbid Anatomy, p. 214.

‡ Those cases in which the food is vomited, when the pylorus remains open, are very interesting. Dr. Watson has shewn that the "pylorus" is a sphincter muscle, the natural and habitual state of which is contraction: it yields, in health, to the pressure of the digested aliment which is driven forwards by the muscular fibres, which compress and surround the pyloric end of the stomach. Of course, when the natural outlet is closed, the food will be thrown up again; but even when open, from the ulcer involving the pylorus, the propelling force cannot be exercised. Should the pylorus be closed, the disposition to hypertrophy in the muscular coat is conservative but in very thin and delicate people (more particularly, according to our experience, in females), the muscles are never sufficiently strong to conquer the impediment; the consequence is, that meal after meal is retained; the distended coats become thinner and thinner: so long as, by vomiting every now and then, the organ can relieve itself, the patient lives, or rather lingers, through a miserable existence, until the power to reject the contents of the stomach ceases, and death takes place.

|| Medico-Chirurgical Transactions.

¶ Practice of Physic, vol. II, p. 414.

of the disease, has little or no vomiting. These are all points of great practical importance, and direct us, in some degree, to the *situation* and nature of the disease. It has long ago been pointed out, that when the ulcer is situated, as in the case of Mr. F—, near the pylorus, the pain is much greater than when it is placed in the middle of the stomach; and we can readily conceive why an ulcer placed at or near either opening of the stomach, should give more pain than when attacking the intermediate parts, in either curvature.

When the ulcer is situated at the entrance to the stomach, the disease has symptoms very similar to those of stricture of the œsophagus; but the food, generally, gradually passes in the right direction, and then for a time the sufferings of the patient are over. This I have observed in a case in St. George's Hospital, under the care of Dr. Seymour.

Mr. Kiernan examined the body of a gentleman after death, in whom the pain had been unusually severe, and found, on a careful dissection, that the *scirrhous mass* had surrounded the trunk of the gastric branch of the par vagum, which in fact ran directly into it.

The emaciation has already been alluded to: not but that we have seen patients more reduced than this man; still, as his wife said, he was a mere shell when compared with what he had been two years before. Although not always a symptom of malignant disease of the stomach, wasting of the body has been observed in every patient dying of this disease that I have seen. Napoleon Bonaparte is said to have been very fat when he died; his omentum remarkably so. The fat is said to have been "upwards of an inch thick on his sternum, and one inch and a half upon his abdomen."

It will have been remarked, that, a few days before death, the pain, sickness, and vomiting, were urgent, even when the stomach was kept without food, and the thirst mitigated by permitting a bit of ice to dissolve slowly in the mouth. The vomiting on the 10th also began to resemble coffee-grounds, and was very offensive, affording almost certain evidence of organic disease of the stomach. From this time, the powers of life, too, rapidly declined. This was also the case in another patient under the care of Mr. S. Parker, a few months ago, whom I saw two or three days before he died, and whose stomach was found diseased, on examination after death, from the cardia to the pylorus. Here, as in the case of Mr. F—, the matter ejected resembled coffee or chocolate grounds, or lees of wine; and the patient rapidly sank after this symptom was present. The dark matter was evidently blood extravasated from the disorganized surfaces, and changed by exposure for a sufficient time to the action of the gastric juice. So far as we know, this kind of vomit generally ushers in a rapidly fatal termination. It is also interesting, as teaching that a mechanical obstacle is not the only cause of vomiting in cancer; for we see that, independently of any mechanical obstruction, and where no food of any kind has been taken, there may be repeated and copious vomiting, from the morbid irritability of the stomach in the advanced stages of the disease, and more particularly when the surface of the organ is denuded by ulceration.

Cruveilhier relates a case the symptoms of which, during life, were somewhat similar to Mr. F—'s; that of Madame A—, aged 42 years. The symptoms were, perpetual vomiting of mucus and food for three months; then hæmatemesis came on, and the lady died in three weeks. All treatment was ineffective, even to palliate. On examination after death, *encephaloid vegetations* were found in the stomach, chiefly about the pyloric half. One obstructed the pylorus.

2. POST-MORTEM APPEARANCES. Cancer was not observed in any other organ of the body; and I believe, notwithstanding the fact that cancer is a constitutional affection, or, at any rate, if local and solitary at first, is apt to disseminate itself, that, when it attacks the stomach, it is accompanied less frequently than some other modes of carcinomatous disease by cancer in other parts of the body.

The peculiar bright redness observed at the cardiac portion of the stomach was a feature of much interest, not

mentioned by any author I have met with, in connexion with a fatal disease of the pylorus, such as was present in this man. The researches of Dr. Yelloly, M. Billard, and Morgagni, are very interesting. The first-named physician conceived that these patches are not to be regarded as unequivocal marks of disease of the stomach, inasmuch as they "occur in every variety of degree and character, under every circumstance of previous indisposition, and in situations where the most healthy aspect of the organ may be expected": an opinion fully confirmed by Dr. John Abercrombie.

Cruveilhier describes the anatomical characters of the simple ulcer of the stomach to be spontaneous loss of substance; ordinarily circular, with well-defined edges; the bottom of it greyish and dense; of variable dimensions; almost always in the lesser curvature or posterior wall of the stomach; sometimes as a zone in the pyloric orifice. He remarks, also, that the simple ulcer is almost ever solitary.

The simple ulcer differs from the cancerous ulcer in the character of its base, and the absence of circumscribed hypertrophy, which always attends the latter.

The symptoms are described by this eminent writer to be emaciation, constipation, nausea, vomiting, hæmatemesis. The cases he gives, as illustrative of this disease, are such as have died from perforation without preliminary adhesion and consequent peritonitis. This adhesion is mentioned by Cruveilhier as one of the ordinary attendants on ulceration.

The distinction between simple ulcer and cancerous ulcer of the stomach is still further illustrated by the curability of the former. Two cases are quoted by Cruveilhier, of death from perforation, as a sequel of simple ulcer; the opening being found at the border of a cicatrix of an old ulcer, the relic of a previous disease. The progress of one of these cases extended over a period of more than twenty years.* There is no case illustrative of the vermilion injection of the mucous membrane observed in the stomach of Mr. F—.

3. TREATMENT OF SIMILAR CASES. The treatment of the advanced stages of a disease, which may be fatal by gradual exhaustion after long-continued suffering, by fatal hæmorrhage from the ulcer, or by perforating the stomach and permitting the contents to escape into the cavity of the peritoneum, giving rise to extensive peritonitis, can at the best only be palliative. Prussic acid, opium by the mouth, or anodyne enemata, and nutritive injections, when food cannot be retained, may afford some little comfort; but of one thing we are certain, *that the less we put into the stomach, in the way of medicine or food, under these painful circumstances, the better.*

But can anything be done in the first stages of these diseases of the stomach? We have already pointed out the important diagnostic mark of Cruveilhier, that *simple ulcers* of the stomach may be distinguished from *malignant*, by the former admitting of cure; and our treatment must be directed in the hope that the disease is not malignant; and even when we have every reason for supposing that chronic inflammation has ended in ulceration, we must not altogether live without hope. The possibility of the cicatrization of ulcers, once doubted, is now fully ascertained. The process certainly takes place with difficulty, having many obstacles to contend with; but there are now few pathological anatomists who have not met with instances in which some intestinal ulcers were in full activity, while others were healing, and a third set completely cicatrized.†

In a case in which we had reason for suspecting ulceration of the stomach, the treatment we should reply upon, in the first instance, would be, leeches, counter-irritation, prussic acid, and, in some patients, small doses of nitrate of silver. The treatment will of course demand great perseverance and patience; but we know that, if the patient have not the scrofulous diathesis, he may recover from a condition apparently the most desperate. Of course, each case

* Cruveilhier, *Léçaison* xx.

† Vide Dr. Hope's *Morbid Anatomy*, §g. 167 to 170.

will require modifications of treatment, which must be left to the tact of the medical attendant to regulate; but, in reference to the disease itself, I would remark, that the smallest possible quantity of food, and of the least irritating nature, is absolutely to be insisted on: wine, spirits, ale, should be avoided, and even the mildest kind of food, such as milk, arrow-root, etc., must not be given in sufficient quantity to distend the organ. As the emaciation, during the progress of the disease, often becomes very great, some food must be given to support life. The difficulty in the treatment consists in steering between the two extremes; but, so far as my experience teaches, the danger is *greater* of giving *too much* and too stimulating food, than *too little*. If we have a choice as to the kind of food, it is for a diet consisting, as proposed by the late Dr. Barlow, wholly of fresh-made curds; and even of this a small quantity only is to be taken at a time. Aperients always do harm, and are therefore, if possible, to be avoided. The bowels can be kept open by clysters of warm water, and the powers of life may also be sustained by injections of beef-tea, by which the necessity for food taken by the mouth is lessened, and the diseased stomach longer permitted to enjoy that perfect rest, which is so very important.

Sheffield, Jan. 1st, 1853.

CASE OF INTERNAL UTERINE HÆMORRHAGE.

By GEORGE KING, Esq., Surgeon.

IN the *Provincial Medical and Surgical Journal* for 31st March, 1852, I published a case of internal uterine hæmorrhage. The subjoined is another case of the same class, which recently occurred in my practice.

CASE. On Sunday, Sep. 5, 1852, I was sent for to see Mrs. T., a patient whom I had attended three times before in her confinements, and who had always had a quick and natural labour. She was now, as she supposed, in her last month with her fourth child. Not expecting for a month or five weeks, she had taken lodgings for a week or two on a hill about a mile from the city, for the benefit of the children's health, as well as her own. On the morning of the day when I was called in, she was preparing to go to church with her husband and family, when a wasp stung one of the servants. This trifling incident caused great commotion in the house, and so upset Mrs. T. that she did not go to church, but lay down on the bed. The account the woman of the house gave me was—that, soon after the husband and family were gone to church, Mrs. T. complained to her of a slight pain in the back, with a little discharge, and she felt altogether very unwell; and soon after she had a very copious motion, which she (the old woman) thought *smelt very deathly*. Here the old woman's olfactory organ was at fault. She had fainted twice in about an hour. They both became alarmed; and at half-past twelve o'clock the husband was called out of church. Immediately on his return to the house, a servant was sent off for me.

It was about two o'clock when I saw her. I found her then on the bed. She appeared much depressed, and complained of tingling pains in the back, and she thought that labour would very soon come on. On examination *per vaginam*, there seemed to have been no discharge, and I found nothing more than the usual premonitory symptoms of approaching labour. In the parturient passage the mucous secretion was very abundant, and the parts most amply lubricated. The os uteri was thin, and sufficiently dilated for me to introduce my finger with ease. Having fully satisfied myself that there was no external hæmorrhage, or any other alarming symptom, I did not interfere. I was with her about two hours. During that time there were no labour-pains, but she still continued to complain of great sinking, and fainted once, and was also sick; still this did

not improve her condition, (sickness often excites labour-pains). As she seemed much exhausted, I gave her a table-spoonful of brandy twice, but she kept yawning, and did not rally. The pains were alight, and less frequent, and not so strong as when she was first taken. Yawning and fainting occurring during labour, are unmistakable symptoms of mischief going on: they must always be looked upon with suspicion, and must create in the mind of an observant obstetric practitioner some degree of alarm, and will require his most prompt and active assistance. As there was no advancement at half-past four o'clock, I then gave a dose of ergot, but it did not increase the pains much. On making another examination, I found the os uteri a little more dilated, and a pouch of the membrane presenting, about the size of a filbert; this I ruptured, but only a very little liquor amnii escaped. I then discovered that it was a natural presentation, and was satisfied that if the pains followed I had nothing to apprehend. Shortly after the membrane was ruptured, the pains became stronger and quicker, and in about two hours a dead child was born, without any unpleasant symptoms succeeding. Before the placenta was expelled, and in a few minutes after the child, a large clot came away with a very slight pain. Although it was not very large, this fully explained the fainting and the other unpleasant symptoms which had been observed during the day. The clot had no doubt been accumulating ever since the first fainting-fit in the morning; and would have gone on until checked by fatal syncope or labour. The vessels had no doubt ceased to bleed the moment the membranes were ruptured, and the formation of the clot was stopped by the expulsive action and contraction of the uterus. That took place in the afternoon, without producing the slightest appearance of anything like internal or external hæmorrhage. It was very evident, from the appearance of the child, that it had not been dead long, and it was very clear that the mother had not gone her full time. She had herself expected to go three weeks or a month longer. I examined the placenta immediately after it was expelled, and there was a rent in its membranous covering, at the root of the umbilical cord; and on the surface of the placenta itself there was a large thick coagulum extending over it, an inch and half in circumference, which was very easily removed. This coagulum was no doubt nature's plug, which had put a stop to the hæmorrhage, and all the other unpleasant symptoms.

I need not here enter on the pathology of the utero-placental circulation, nor on the intricate subject of uterine susceptibility; but we all know, and those of us who have had much midwifery practice must have noticed that, at the placental end of the cord, the umbilical vessels are very large, particularly the umbilical veins. From this point they ramify, and are distributed over the whole membranous covering of the placenta, till lost in the substance itself; and from this point, also, springs, and is conveyed, the nourishment to the fœtus in utero. Thus, a rupture, or hæmorrhage, or any disorganisation taking place at this important and connecting link and vital union between the mother and the fœtus in utero, must be attended with very serious, if not fatal consequences, both to the mother and child; and would be calculated to produce the symptoms and all the great constitutional derangement, of which my patient complained, and from which she was suffering before the child was born, when I was first called in; and is another strong proof of the powerful influence and the great effect of passion and mental impression on the mother's system, and on the fœtus in utero. There is not here the slightest doubt that the agitation and commotion of the mother's mind, caused by the sting of the wasp, must have produced a shock to the whole system, the effect of which was so powerful, as to produce the copious evacuation from the bowels, and consequent great exhaustion; and no doubt it was a sudden and violent movement of the fœtus that tore the membranous lining of the placenta, and lacerated the umbilical vein; and here was the cause of the internal hæmorrhage which caused so much uneasiness during the day, and would soon have caused the death of the

mother, as well as of the child, if labour had not been quickly brought on. The bleeding, I expect, ceased as soon as the expulsive action of the uterus was set up. The child did not appear to have been dead long; and had the labour been a rapid one, I have no doubt but it would have been born alive. The mother recovered very well. The milk, as is usual in such cases, gave her some little trouble.

As there are but few cases of *internal* uterine hæmorrhage published, this, perhaps, may be interesting to the readers of the *ASSOCIATION JOURNAL*. What I wish particularly to direct their attention to is, the simple cause that produced it, and the slight hæmorrhage that gave rise to such great and alarming constitutional derangement in the mother, and to the death of the child. Here was only one clot, and but very little discharge afterwards. Query—Could any other plan of treatment have saved the child?

Beth, December, 1852.

BIBLIOGRAPHICAL NOTICES.

WHAT TO OBSERVE AT THE BEDSIDE, AND AFTER DEATH, IN MEDICAL CASES. Published under the authority of the London Medical Society of Observation. 12mo., pp. 136. London: 1853.

THIS work points out with minute and elaborate detail the method to be pursued in making clinical examinations regarding patients during life, and in examining bodies after death. The value of such a guide will be felt by all who have to attempt the diagnosis of puzzling cases; as it will enable them to explore every symptom and every part of the body, according to a plan which prevents any possible source of information from being neglected: but if the busy practitioner attempt to adopt it as his *usual* text-book of diagnosis, he will often, we doubt not, bewilder his memory and his judgment amid the unimportant features of his ordinary as well as of his extraordinary cases. The time of even moderately well employed practitioners is too precious, to enable them to subject many cases to the searching scrutiny proposed by the Medical Society of Observation; nevertheless, the little volume before us will be found a useful aid in the diagnosis and accurate reporting of cases, even by those who have not leisure to follow the elaborate system of inquiry which it recommends and explains.

The circumstances in which the book is published are thus unfolded in the preface:—

"Soon after the Medical Society of Observation had been formed, it was felt by the members, that the labour of analyzing and comparing clinical observations would be greatly lightened, and the precision of the observations themselves increased, if the records of these were in every instance arranged on an uniform plan. The society in consequence adopted, with some modifications, a form of arrangement of symptoms and after-death appearances, which had been framed by Dr. Walshe. The publication of this form seeming desirable, it was referred to a committee, who expanded and altered various parts of it, and finally threw it into its present shape. The supervision of the whole was intrusted to Dr. Ballard, who has bestowed upon his task great labour and attention.

"The society believes that this scheme or method of arranging the clinical and anatomical phenomena of disease, will prove useful both to those who desire to learn systematically with what amount of detail, and in what order, those phenomena should be looked for, and also to those who wish to record with accuracy the results of their experience. It will probably be admitted, too, that errors in diagnosis are more frequently traceable to forgetfulness in searching for all possible evidences of disease, than to misinterpretation of those actually discovered: the physician proceeding to the investigation of an obscure case may, then, in a book of the present kind, occasionally find a useful remembrancer."

AN INTRODUCTION TO CLINICAL MEDICINE: Six Lectures on the Method of Examining Patients; Percussion; the Use of the Microscope; and the Diagnosis of Skin Diseases. By JOHN HUGHES BENNETT, M.D., F.R.S.E., Professor of the Institutes of Medicine, and of Clinical Medicine in the University of Edinburgh. Second edition, with numerous woodcuts, 12mo., pp. 134. Edinburgh: 1853.

THIS is an excellent manual for the student; and, indeed, there are few practitioners who may not derive advantage from its perusal, not only from the clear and condensed information which it imparts, but also from the useful counsels which it gives as to the manner of making and recording observations at the bedside and in the dead-room. A chapter on the application of chemistry to diagnosis would be a useful addition, and we hope to see it supplied by Dr. Bennett at no very distant period.

MANUAL OF HUMAN ANATOMY: Descriptive, Practical, and General. By ROBERT KNOX, M.D., F.R.S.E. Illustrated by 250 highly finished wood-engravings, from drawings by Dr. Westmacott. 12mo., pp. 672. London: 1853.

As might be expected, this manual, proceeding, as it does, from an accomplished veteran in the art of teaching anatomy, is eminently luminous and graphic. We fear, however, that many old students of the author will be somewhat disappointed in turning to the *sphenoid bone*, the *humerus*, the *femur*, or other remembered theme of "Old Surgeon's Hall", to find that scarcely a trace can be discovered in any part of the volume, of the racy parables by which the oral lectures of the author were wont to be enlivened; and by the happy introduction of which he was able to command the attention of even the idle and the indolent.

PERISCOPIC REVIEW.

PSYCHOLOGY IN ITS RELATIONS TO PATHOLOGY, THERAPEUTICS, AND JURISPRUDENCE.

OPIUM IN MENTAL DISEASE.

In the *Psychological Journal* for October 1852, there is an analysis of the views of Dr. ENGELKEN, of Obermeuland, on the employment of opium in mental disease, and some allied conditions. He considers the drug to have a twofold action—one local, on the nerves of the stomach, the other remote, on the nervous centres, by absorption into the blood. He adduces the example of the oriental opium-eaters, in justification of its administration and long-continued use in large doses. He has exhibited three grains with benefit once or twice a day, for periods of three or four years. The appetite has improved—the entire frame has been benefited—and there has been decisive amelioration of the mental malady. He has observed that small or half-grain doses are followed by increased rapidity of the circulation, and of the quantity of the secretions. If the dose be raised to a grain, or a grain and a half, the actions of the brain are increased, and there is diminished susceptibility of external impressions. Thoughts are developed more rapidly, and with greater clearness; the association of ideas is more varied; and the imagination is more active. Doses from three to ten, or more grains, produce the well-known phenomena of stupor. He regards the medicine as contra-indicated in insanity depending upon inflammatory or congestive conditions. He recognizes its suitability in those forms of hypochondriasis which most closely approach to melancholia; but does not appear to be acquainted with its utility in general insanity, and in the latter stages of mania, in doses of one or two grains, gradually increased to four or six grains, combined with calomel and digitalis, as recommended by Dr. Seymour. Dr. E. confirms the opinions prevalent in Britain, of the benefit to be derived from opium in deli-

rium tremens and puerperal mania; and adds chorea to the list of nervous diseases, in which he has tried it with decided success.

HOMICIDAL MANIA.

In the same periodical, there are presented descriptions of three forms of homicidal mania, as inferences from an analysis of the case of Jobard, who destroyed a female, a stranger to him, in the public theatre at Lyons, *apparently* for the purpose of avoiding the crime of suicide by committing that of murder, the investigation of which would secure him time for repentance, but *probably* while acting under a morbid impulse.

1. *Moral Homicidal Mania*, arising from a morbid state of the feelings, passions, and propensities, which the powers of the understanding, reason, judgment, cannot control nor counteract. Acts of impulsive homicide come within this category.

2. *Intellectual Homicidal Mania*, arising from some disease of the imagination, some delusion or hallucination, or misapplication or perversion (which often happens in religious monomania) of the reasoning faculties. This variety of the disease is always primarily dependent on some lesion of the understanding.

3. *Moral and Intellectual Homicidal Mania*, arising from some morbid state of the feelings, passions, and propensities, affecting and impairing the controlling influence of the intellectual faculties.

The existence of the first variety has been a matter of dispute. It is admitted by psychologists; it is repudiated by jurists. Is the tendency to kill a vice or a disease? Is the impulse irresistible and involuntary, or the result of such affection of the will as to render the actor irresponsible? Tests or grounds of distinction between a diseased and a vicious inclination have been anxiously sought for. The most recent attempts have been by Michéa and Guislain. Michéa (*Ann. Médico-Psychologiques*, July, 1852), conceives that in individuals labouring under dyspepsia, disorders of menstruation or of the muscular system, under the disturbance of the puerperal condition, under hereditary predisposition, in spermatorrhœa, and especially in spontaneous anesthesia of the skin, we are entitled to recognize and treat eccentric, or extravagant, or revolting desires and tendencies, as symptoms of disease, and not as acts involving culpability, or exposing to punishment. Guislain (*Leçons Orales sur les Phrénopathies*, i, 255), suggests that a correct estimate of the depravity or the disease, of the responsibility or the irresponsibility of the individual, may be formed from the following circumstances:—the cause of the disease, the existence of hereditary tendencies, the education, degree of intelligence, manners, conduct, or ruling passion of the patient, pregnancy, the co-existence of any disease, but especially of nervous affections, as hysteria, catalepsy, epilepsy, and somnambulism, the circumstances preceding and accompanying the act, the physiognomy, the tendency to periodicity in pathological conditions, the momentary suspension of sensibility, and the motive or absence of motive.

INSTANTANEOUS INSANITY.

Intimately connected with the subject of homicidal mania, are some observations on instantaneous insanity, contained in an article by Dr. BOULEAU DE CASTELNAU, in the *Annales d'Hygiène*. All the instances of sudden and uncontrollable impulse adduced, are illustrations of homicidal mania. The development of these states is described as being preceded by no reasoning, by no process of thought naturally tending to suggest such an action, nor by reasoning in opposition to the laws of reason; as occurring where no predisposition to insanity existed; as being dreaded and opposed by the individual, and published by him, that precautions might be taken to render innocuous the destructive impulse which he could not resist. Marc, one of the highest medical authorities on this subject, Talma, the celebrated tragedian, and Professor Lichtenberg, are quoted, as having experienced this blind appetite to destroy the life of others. A large number of the cases attributed to this momentary insanity occur during some uterine disturbance; or immediately subsequent to deep congestive sleep. Georget's aphorism—that a horrible act, a murder, or an arson, committed *without cause, without motives of interest*, by an individual whose actions have been previously correct, must be the result of insanity, is lauded; but the author's own conclusions are:—1. Instantaneous alterations of the mental faculties occur, inducing instantaneous insanity. 2. The first manifestations of this sudden change may be what is styled a crime. 3. Persons committing such an act should be placed in an asylum specially set apart for such cases. 4. They should remain there until

examined and certified by a special jury. Guislain gives an instance where a murderous propensity was developed in a child four years old, who attacked another aged six months.

FEUCHTERSLEBEN'S DIETETICS OF THE SOUL.

Dr. FEUCHTERSLEBEN is well known in this country, from his *Principles of Medical Psychology*, published by the Sydenham Society. The object of his recent work, on the *Dietetics of the Soul*, is to develop and elaborate the truth, that the mind has great power in preventing and curing as well as in causing its own diseases. The tone is more ethical than medical; it is transcendental in style rather than in subject; and, although the whole course of the speculation is somewhat foreign to our indigenous modes of thinking, many valuable and suggestive views will be met with upon that ill defined and difficult branch of therapeutics, the moral treatment of the insane. It is not asserted that many of these opinions have been more ably and more clearly discussed by Barlow, in treating of man's power over himself to prevent or control insanity; or by Dr. Holland, in his chapters on the effects of mental attention on bodily organs; but it is incumbent upon us to allude to these authors as congenic with Feuchtersleben, and as having opened up in this country the same deep vein of thought.

The principal object of the "Dietetics of the Soul" is declared to be to communicate whatever may be learned of the mental act of faith as a curative process. If confidence in our medical attendant has contributed to our cure—are we less cured, it is asked, than if iron or bark had effected our recovery? Are we deceived when we find that confidence renders us as much service as the physician himself? Shall we be forbidden to attain the knowledge of acting for ourselves, or to direct the art of self-deception to any useful end? The author dwells upon the influence of impulses in particular states of mental obscurity—of the operation of the will when independent, or when acted upon by the consciousness of others in resisting external impressions, quoting an assertion of Goethe that he had warded off the contagion of putrid fever by a simple volition; of the protective and tonic power of the conscientious fulfilment of duties, and of self-activity as the condition of self-preservation. Men seldom die upon a journey or during their honeymoon. In introducing the theory, that disgust at illness, and a reliance upon the beautiful and loveable, and a conformation of mind which derives pleasure from every event, are intrinsically conducive to the preservation of serenity and sanity, the diagnostic powers of Dr. Heine of Berlin are mentioned, as enabling him to distinguish the various diseases of the skin by their odour alone; and as likewise possibly enabling him to discover moral peculiarities (p. 25). In discussing the effects of the imagination, Kant is represented as regarding dreaming as an exercise during sleep, intended by Nature to maintain the organic machine in a state of vital activity. We are called upon to admit that what can cure may likewise prevent—so that the influence which renders a disease fatal, may also be the means of inducing it. If we are ill, because we believe ourselves to be ill, the author suggests that there seems no reason why we should not be able to keep ourselves in health, by the firm conviction that we are healthy: that by esteeming our brother to be good, he is so: that confidence in the half virtuous man renders him wholly virtuous; that by the encouragement of a pupil in the assumption that he possesses certain faculties, they will be developed in him: that, in fact, to imagine, hope, or believe firmly, is tantamount to accomplishment.

In a chapter on character, ill-humour, and distraction, the former is defined to be a highly cultivated will; deliberation is defined to be a disease of the mind, which can only lead to unhealthy action; distraction, described as a means of dissipating painful, disturbing powerful, and rousing from torpid trains of thought, is condemned, and concentration—the fixation of the will upon our actions—recommended as the most potent curative resource. If a man conceives that he is devoid of the force necessary to direct himself, let him place himself in some position where he must act. Notwithstanding this proposition, the influence of external impressions is fully admitted; for in a few pages it is stated that "in a cheerful, orderly apartment, a man's feelings become cheerful: they partake of that which surrounds them". The agency of mental serenity, and the equable development of the faculties, in imparting vigour, and in carrying the mind clear and energetic beyond the usual period of decrepitude and decay, is illustrated by such examples as Isocrates, who shone as an orator in his ninety-fourth, and Fleury as a statesman in his ninetieth year. While it is admitted that in the present age mental power has been more attended to than that mental culture which

secures health and longevity, and that the premature and excessive exercise of the intelligence may have affected the bodily health, the proposition is advanced, that if intelligent, clear-minded individuals be watched, it will be found that they complain of mental and physical indisposition less than persons who consider sensual enjoyments to constitute the real happiness of this world. A strong appeal is, notwithstanding, made in favour of the beneficial influence of the active mental impulses; of the power which certain passions, or exaggerations of our tendencies, have in overcoming other passions. We can never neutralise any affection by reflection alone: we can scarcely moderate it; but one affection will drive out another. Love and pride, annoyance and friendship, mirth and anger, are examples. Plato called passions "fevers of the soul"; because, like febrile affections, they are crises which often cure the most deep-seated evils by a purifying and refining process. Yet, according to Feuchtersleben, strong passions rather belong to weakness. Misfortune, which subdues the innermost seat of our strength, the mind, exerts our passions in a powerful manner. Two principles are laid down as to our affections—that happiness is not the reward of love, but love itself; and that we are not happy because we control our passions, but that we control them because we are happy. In a disquisition on oscillation, or that constant alternation of tension and relaxation, sleep and waking, joy and sorrow, which make up the sum of moral being, we are told that we must learn to know and govern ourselves: we must cultivate our moral and intellectual faculties, and then only shall we know what is meant by the term health, by the integrity of man: that in this attempt every one can do what he *should* do: that it is not only necessary to listen to the warning voice of suffering amidst the intoxication of joy, but even to endeavour to draw it forth from the innermost recesses of our being: that pleasure presupposes suffering, and that suffering is the spur of human activity, and necessary for the formation of character.

Hypochondriasis, in its most formidable and monstrous form, is characterised as the offspring of selfishness, indolence, and pedantry, and as acknowledging the mawkish spirit of modern literature as its nurse. But this giant evil may be annihilated by disease. Make the hypochondriac ill, that he may know what illness really is, and you cure him. The grand panacea for all mental infirmity and disease is the study of nature—the worship of truth. At present we are nothing, because we are false, and therefore diseased. Let us turn our clouded sight from the narrow sphere of miserable tortured self to the boundless theatre of suffering or rejoicing humanity, and forget personal miseries in sympathy with our fellow men.

Appended to the main treatise is a *psychological diary*, intended to serve as a series of formulae, and as a model of what each mind should prescribe for itself. In it are to be found the following aphorisms, which owe something to their epigrammatic form, and something also to their truthfulness.

An excessively tender conscience, overrating its own importance, may induce hypochondriasis, unless counterbalanced by great activity. Our minds are so constituted, that a change of objects brings nearly as much relief as actual repose. The fearful germ of insanity slumbers in every man's mind: watch and strive with all cheerful activity that it awake not from its slumber. The gloomy, romantic dreamer should be trained to walk with head erect, to look others straight in the face, to speak in a loud, distinct tone of voice. I can affirm, says Dr. F., from personal experience, that such habits exercise a great influence both on mind and body. We should treat ourselves as Reil did his patients; the incurable lost life, but never hope. Composition, even when we have no idea of appearing in print, is an excellent dietetic tonic. The best and quickest mode of banishing a painful impression is to give it expression in words. Life may be considered and regulated in two ways. We may either consider ourselves as a central point, and endeavour to maintain life against the influence of external agents, seeking to increase our powers by the development of character; or we may abandon ourselves freely to the world, and endeavour to assimilate ourselves to external things, considering and making ourselves a portion of the universal whole.

GUISLAIN'S LECTURES ON MENTAL PATHOLOGY.

[*Leçons Orales sur les Phrénopathies*: 1852.]

GUISLAIN is not only the most eminent of the psychologists of Belgium: he called the school into existence, and still represents its strength and peculiarities in his own person. An accomplished physician, with a taste for metaphysics, and of large and active benevolence, he combines some of the most

important qualities for the situation he holds. In his own country he is known as the ardent advocate for the erection of asylums to meet the necessities of the population, and for information in the general management of the insane; in England, as the author of several excellent treatises on Mental Diseases. His latest success has been the establishment of clinical teaching in connexion with the institution under his charge. His first course of lectures is now published, and constitutes an approximation to a systematic treatise on the subject of which they treat. We have heard a physician say, that the first time he entered an asylum in this country was to be installed as its future superintendent. Dr. Guislain modestly says that his *debut* was distinguished by his comprehending nothing of what he saw. His mission was to remedy and remove this public misfortune and absurdity.

His first volume, containing seventeen lectures, is devoted to the phenomenology of mental disease. He is first engaged with the physiognomy: insists much on the colorisation of the skin of lunatics, interpreting pallor of the face and lips as indicative of concentrated passions, instead of attributing such a hue to an anæmic condition of the system, as has been general in this country. He formulises the interrogatories to be used during the examination of a patient: recommending a series of questions commencing with "*Why*" as a test of intelligence: another commencing with "*How*," to exhibit the amount of reason or judgment: a third, containing "*When*" and "*Where*" as an appeal to memory: and a fourth intended to estimate the powers of calculation, by such expressions as "*How much*?"

In addition to all other evidence as to the real, but perhaps unrevealed and undiscoverable condition of the insane, the frequent examination of their correspondence and composition is insisted upon.

Alienation is defined to be a morbid, apyretic, and chronic derangement of the mental faculties, which deprives man of the power of thinking and acting freely, in relation to his happiness, preservation, and responsibility. The difficulty of excluding from such a definition cases of eccentricity, of fanaticism, of crime, of mere intellectual feebleness, is admitted; and special exemptions, founded chiefly upon the history of the individual, are recorded in favour of disturbers of the public peace, religious martyrs, the profligate, and the visionary.

Objecting to the terminology now in use, a revolution is proposed: and under pretext of euphony and capacity for adaptation, the radical *phren* is substituted for *psyché*, and accordingly Phrenalgia is the successor of Melancholia, Hyperphrenia of Mania. As Dr. Guislain recognises a hundred forms of insanity, and as many monomanias, as there are elementary forms of alienation, and as there are elements in the human character, a vast augmentation of our vocabulary would ensue, did not he practically adhere to the more antiquated and catholic nomenclature and arrangement. The primitive orders are—1, Melancholia, or predominance of the depressing emotions. Under this head are found remarks on the creeping sensation, experienced by melancholics under the scalp, and along the extremities: on the cyanosis, met with during despondency, which is, in this place, attributed to disorders of the organs of circulation: on the rapid emaciation invariably observed: on the occurrence of instances of the disease, where there exists no disturbance of the intellectual powers: on the modifications impressed upon the disease by association with an erotic, nostalgic, misanthropic, or hypochondriac tendency: on the proof afforded that hypochondriasis is a genuine disease of our moral being, by its frequent transformation or mergence into other species of alienation: on the frequent association of hypochondriasis with nervous diseases of the heart, with affections of the pericardium, gout, and spermatorrhœa: on the greater frequency of recovery towards the first or second year than at other times: on the announcement afforded of the transition of melancholia into incurable chronicity, by the relaxation of the muscles of the face, change of expression, and inattention to neatness and cleanliness. 2, Ecstasy, Phrenoplexy, suspension of all intellectual acts, with general muscular rigidity. Insensibility to external, even painful impressions; statuesque attitudes persevered in for an incredible length of time; taciturnity; immobility—so that the patient does not even wink, and the peristaltic motion of the intestines is arrested; abolition of mentalisation, are the chief characteristics of this affection. It was conceived to be generally found in connexion with religious excitement or mysticism: Dr. G. is disposed to deny this. The disease is not frequent in Britain, but it certainly exists. 3, Mania, Hyperphrenia; exaltation of the moral feelings. The pathognomonic character is expressed thus; exaggeration, exaltation, agitation, aggressive passions. Tranquil Mania is, however, noticed, in which there

may exist merely a ruling passion, a slight incoherence of ideas, and hysterical or convulsive complications; and which has often led to the prison or the scaffold those who should have found shelter and reason in an asylum. This species is allied to the *Manie Raisonnante* of Pinel. The special forms most fully described are *Cleptomania*, or the tendency to steal, and its frequent connexion with pregnancy and the puerperal condition: *Dipsomania*, the tendency to inebriation, its appearance as a consequence of intemperance, as a symptom of simple mania, and its influence in the production of the General Paralysis of the insane: *Erotomania*, its frequent development contemporaneously with the suppression of the catamenia: but its distinction from nymphomania, in which there is local excitement or disease of the sexual organs. The connexion of the disease of lust and the disease of fanaticism is traced. *Choreomania* is arranged as a variety of the monomania of joy and dancing; its influence in the production of the convulsive epidemics, which have from time to time disgraced the religious world, and impeded the progress of Christianity, is adverted to, and the connexion of such conditions with concentration, or fixity of thought (monoideism), very briefly hinted. *Theomania* is remarked to be much less frequently met with in Belgium, as in this country, than religious melancholia. Of 100 melancholics, 58 presented religious aberrations; of 100 maniacs, not one had religion for an object. *Logodiarrhœa*, or logomonomania, must be well known to all who have visited or lived in asylums, by experience, if not by designation. Loquacity is now, we presume for the first time, elevated to the rank of a distinct mania. The wandering, climbing, obscene, sanguinary tendencies of the insane are regarded as examples of forms of Mania, rather than as subordinate and occasional symptoms. It is shrewdly observed that in melancholia the patient accuses himself—in mania he is a victim. The incontinence of urine; the exhalation of a fetid odour from the skin, doubted by Jacobi, and by English physicians attributed to inattention to cleanliness; and the suppression of the menstrual discharge, are enumerated as important premonitions of a paroxysm of mania. Dr. Guislain is led to regard some cases of periodical mania as transformations of the epileptical attack. He never saw a true attack of apoplexy occur during the course of mania; but the sudden deaths which he does report, somewhat weaken the force of this assertion. 4. *Folly*, *Paraphrenia*, anomalous affections of the will. The patient thus attacked is forced to some singular or repulsive act, or course of action, without knowing why or how, although there may exist no disturbance or incoherence of the ideas. As the sport of such impulses may be classed together lunatics who pick, mutilate, and destroy property, themselves, or others, or the remains of others; who do not speak for years, who do not eat or drink for months; who retain their fœces, or devour them; who burrow, shriek, or declaim. 5. *Delirium*, *Idiophrenia*; anomalies in the ideas, corresponding to illusions and hallucinations, where the aspect of the disease is determined by the nature and relations of the erroneous belief: where a man may be the victim of a plot, or the recipient of a divine revelation; reduced to the size of a monad, or expanded to that of a megatherium; transmuted into an emperor or a wolf. 6. *Dementia*, *Aphrenia*; obliteration or impairment of the moral and intellectual powers. The varieties of this modification will depend chiefly on the amount of enfeeblement. There are many patients who preserve the power and taste to execute painting, music, or mechanism. Dr. Guislain comprehends under this division congenital idiots, imbeciles, and cretins, as well as individuals who have passed from mania into fatuity: or who have become imbecile from fever, phrenitis, or epilepsy. He points out a false dementia, which occurs in the course of other mental diseases; but consists rather in the temporary oppression than the extinction of the faculties. It would appear that the proportion of the cases of dementia has greatly increased in Belgium: that in England there are found about 11 fatuous patients in 100; but at present, at Ghent, 32 in the same number. This augmentation is attributed to the severe privations of the working classes. Frequently these cases terminate in marasmus; but more generally imbeciles live for twenty or even fifty years, devoid of responsibilities or anxieties, and free from their inevitable consequence. They are unexpectedly found dead in bed; or they sink under scorbutus, diarrhœa, anasarca, paralysis of the pharynx, or stricture of the œsophagus. In alluding to the dementia, which accompanies the last stage of the general paralysis of the insane, that disease is affirmed to follow long excitement, dry intellectual labour, excess, intemperance, mercurial or syphilitic diseases, the use of opium or tobacco; and to be ushered in by abolition of articulation, complete deafness, and an attack differing from apoplexy only in the non-appearance of paralysis. Baillarger's

supposed discovery of the greater dilatation of one pupil than another, as a new symptom of the malady, is assigned its true value, by the remark that it exists in other forms of alienation. Such irregularity may be observed in healthy persons. Dr. G. gives in his adhesion to the observation of Calmiel, that paralytics of this kind generally die in the course of the second year: and settles the much disputed question as to the priority of the mental phenomena, to his own satisfaction, by suggesting that occasionally the moral and occasionally the muscular symptoms are initiatory. He compares the aspect and bearing of a paralytic to those of a drunkard—a comparison to be borne in mind where the moral condition of accused persons is agitated.

Dr. Guislain is of opinion that alienation may exist independently of all cerebral disease; but in accepting such a proposition, it must be observed that he appears to limit the expression to the solids within the cranium. His observations are founded, in all cases, on personal experience and examination. He conceives that the pia mater is ordinarily the seat of congestion in the insane. In 100 necroscopies, congestion of the encephalon was found 25 times. He compares this condition pathognomically to blushing from shame, or the injection of the neck and eyes during anger. Four times out of five, mania is not accompanied with true but with venous congestion. He directs attention to serous infiltration of the gray matter; and indicates slight anasarca of the eyelid as a sign of the existence of such a condition; a fact suggesting the explanation current in this country, that dropsy of the vesicular neurine, if it exists, is merely the extension of general dropsy. This condition, as well as its congener serous apoplexy, is frequently encountered in general paralysis. But softening of the gray, or of both substances, Dr. Guislain regards as the most frequent morbid appearance found in those who die of general paralysis. The alteration is found in one-sixth of them. In this condition the gray matter acquires an ashy, green, violet, yellow or brown shade, or is colourless: it breaks down on the slightest touch; it is transformed into a soft, semi-fluid pulp, which adheres to the blade of the scalpel. The lesion is generally of considerable extent, but may appear in the form of ulcers, from the size of a pea to that of a half-crown. The intimate phenomena are described theoretically as excitement by passion, or stimulation by alcoholic liquors; a permanent call and distribution of the circulating fluid into the capillaries; distension and engorgement of these vessels; stagnation of the fluids; and, as established by the microscope, serous transudation into the areolar tissue, accumulation of serous fluids in the tissue of the pia mater, penetration of these fluids into the gray matter, by the canals giving passage to the capillaries, disorganisation and distension of the primitive cells, and displacement of their nuclei. The distended vesicles are represented as ten times larger than in the normal state. *Ramollissement* is then, neither inflammation, nor puriform nor fatty degeneration, nor gangrene; but a *MACERATION* of the cerebral substance, with distension and rupture of the cells. Gluge is referred to as a supporter of this view. His observations were made on the brains of sane persons. This condition is the last of a series of changes, which may commence with the process of assimilation. Mental irritation may be to softening, what inflammation is to other changes. The hyperæmia which often exists in maniacs and melancholics does not necessarily lead to softening. It may exist without paralysis. Thickening of the arachnoid is supposed to be chiefly manifested by obtuseness and clouding of the intellect, immobility and rigidity of the features and limbs, and slowness in the formation of phrases. Induration, distinguished from firmness of the cerebral substance, is found chiefly in chronic and epileptic mania.

The inflammation of the mucous membrane of the intestinal canal, the displacement of the colon in melancholics; the frequency of ovarian disease in female lunatics; the frequency of phthisis in all classes of the insane; its probable connexion with the insufficient alimentation to which they from delusion subject themselves; the contemporaneity of phthisis and tubercular meningitis, are recorded. The connexion of pulmonary gangrene with the refusal to take food, has not been observed so frequently in this country, as it appears to have been in Belgium. Dr. Guislain conjectures that many cases of abstinence should be referred to diseased conditions of the eighth pair of nerves. He is disposed to attribute many of the affections of the lungs and heart in the insane, to their violence, their cries, their habits of restraining the respiration, etc.; and to regard them as consequences of the mental condition, or as occurring in its course.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

UNBLEACHED DISULPHATE OF QUININE.

Under the name of "Hospital Sulphate of Quinine", an unbleached sulphate or disulphate has been introduced into the drug market. It is prepared by Mr. Edward Herring, and is sold by Hulle, of Trinity-street, Southwark, London. In the advertisements, it is stated to be at least as pure, and 20 per cent. cheaper than the white salt.

The following is the account which the proprietor gives of the substance. He says:—"The crystalline form is the same, and is in every respect identical with the usual white article, with the exception of the one being bleached and the other unbleached. In refining the white, or bleached article of commerce, by the usual agency of animal charcoal, the sulphuric acid acts upon the lime of the charcoal, and great care is necessary to preclude the inadvertent contamination of sulphate of lime. The "hospital", or unbleached sulphate of quinine, is prepared without the aid of animal charcoal, rendering the presence of salts of charcoal impossible. The peculiar mode of preparing both the sulphates of quinine of this establishment is being patented, and therefore the process of manufacture will be made public."

We have examined a specimen of the unbleached, or "hospital" sulphate, which was forwarded to us by Mr. Hulle, and we can report in its favour. Save the merest trace of inorganic colouring matter, it contains no foreign substance. It differs in aspect from the pure colourless disulphate, its crystals being larger and denser. Not having made a quantitative examination, we cannot say whether the preparation be a sulphate or a disulphate; but we are satisfied that it consists only of quinine, sulphuric acid, water, and a trace of colouring matter, and that it is therefore as good for medicinal uses as the white and pure disulphate.

We are willing to admit that, as a general rule, it is wrong to sanction the use of medicines which are not absolutely pure, as by so doing, we are apt to afford temptation and facility for their adulteration. We think, nevertheless, that we ought to report favourably as to the value of the unbleached salt, because we have found that for medicinal purposes, it is entitled to be called pure; and because by its smaller price, we may enable many to benefit by its use, who could not afford to employ the white salt.

TINCTURE OF MASTIC AS A HÆMOSTATIC.

It is stated in a recent number of *Schmidt's Jahrbucher*, that Dr. FRANKL has found the tincture of mastic an excellent hæmostatic. He employs it in epistaxis, and in troublesome bleeding from leech bites. It is applied to the points whence the blood issues, by means of a camel's hair pencil. Terzer, a dentist of Vienna, is also reported to have used it successfully in hæmorrhage following the extraction of teeth.

MILK IN ABDOMINAL TYPHUS.

Through the French and Belgian journals, we learn that Dr. THIELMANN, of St. Petersburg, administers from two to four tumblerfuls of milk to his patients affected with abdominal typhus, in all stages of the disease—even when they are in a state of insensibility. He believes that this aliment is not only well borne, but is assimilated, and that it gives a power of resisting the disease. More than one patient, he says, who had been given over as hopeless, has been saved by the milk treatment: and he avers that the inconveniences which often follow the use of broth, and similar articles of diet—such as delirium, meteorismus and diarrhœa—never occur when milk is substituted for them.

HYPOSULPHITE OF SODA AND SILVER AS AN OCCASIONAL SUBSTITUTE FOR NITRATE OF SILVER.

Dr. J. DELIOUX, of Cherbourg, brings the hyposulphite of soda and silver under notice, as a therapeutic agent, in the *Bulletin Général de Thérapeutique* for October 15th and November 15th, 1852. He prepares it by pouring a solution of hyposulphite of soda on oxide of silver, recently precipitated by potassa, until it is completely dissolved. On evaporation, minute crystals of hyposulphite of soda and silver are left. The salt appears as a greyish-white crystalline powder, of sweetish taste, leaving a slightly styptic flavour: it is very soluble in water, but insoluble in alcohol. It becomes black on long exposure to light, but preserves its colour indefinitely when kept in bottles of coloured

glass, or covered with paper. The solution becomes black when exposed to diffused light, but much more slowly than that of the nitrate of silver. When pure, it does not discolour the epidermis nor linen. Its power of coagulating albumen, and hence its astringency, is small compared with that of the nitrate; and its local action is less irritating.

From various experiments, Dr. Delieux concludes: First, that for external use, the hyposulphite of soda and silver may be employed in larger doses than the nitrate of silver; and that in these doses it is much less irritant, and incapable of producing a true eschar: Secondly, that for internal use, if it is sufficiently diluted, there is no risk of injuring the mucous membrane of the stomach. Moreover, as its solution does not coagulate albumen, nor form a precipitate of chloride of silver, it will be readily absorbed by the veins of the stomach.

Dr. Delieux has had an opportunity of administering the salt in only one case of epilepsy. Here it was unsuccessful as far as the epilepsy was concerned; but it produced no blackening of the skin, nor any physiological disturbance beyond excessive hunger. But the author very justly points out that no inference can be drawn from a single case. He gradually increased the daily dose from 5 to 60 centigrammes ($\frac{1}{4}$ of a grain to 9 grains).

As an external application, Dr. Delieux uses the hyposulphite as a substitute for nitrate of silver, in cases where a local alternative is required which shall produce less irritation, and act chemically on the tissues less than the latter salt. It should be tried in obstinate ulcers, as an injection into purulent collections and into sinuses, in chronic fluxes of the external ear and of the nasal fossæ, and as a collyrium in diseases of the eye. Among the latter, Dr. Delieux can only cite from experience cases of acute conjunctivitis, which he has often found benefited, after the inflammatory stage has passed, by a dilute solution of this salt.

Dr. Delieux has employed the hyposulphite of soda and silver most frequently in acute and chronic urethritis; and here he has found it most efficacious, especially in chronic cases, and at the end of the acute stage. He does not set it forth as a specific, nor as pre-eminent among local remedies; but as one to which recourse may be had among others. He generally uses an injection of from 50 centigrammes to a gramme ($7\frac{1}{2}$ to 15 grains) of the salt in 100 grammes (about three ounces) of distilled water. It produces little or no pain, and does not act as an astringent.

ASSOCIATION INTELLIGENCE.

FIRST GENERAL MEETING OF THE METROPOLITAN COUNTIES BRANCH.

THE First General Meeting of the Metropolitan Counties Branch was held at the Hanover Square Rooms, on Tuesday, the 11th instant. Among the members present, were the following:—Henry Ancell, Esq., Norfolk Crescent; T. Snow Beck, M.D., Langham Place, London; John Bowling, Esq., Hammersmith; Isaac B. Brown, Esq., Connaught Square, Hyde Park; George Bury, Esq., Whetstone, Middlesex; Charles T. Carter, Esq., Hadley, Middlesex; Thomas Charles, Esq., London; Charles Cogswell, M.D., Bernard Street, Russell Square; White Cooper, Esq., 19, Berkeley Square; John Rose Cormack, M.D., Putney; R. P. Cotton, M.D., Clarges Street, Piccadilly; Charles Cowan, M.D., Reading; Abram Cox, M.D., Kingston-on-Thames; J. B. Daniell, M.D., Lower Grosvenor Street; John Davies, M.D., Hertford; Samuel Edwards, M.D., Upper George Street, Bryanstone Square; John Forbes, M.D., Old Burlington Street; John Grabham, M.D., Lonsdale Square, Islington; Samuel Griffith, M.D., Wellington Street, Southwark; Samuel Hare, Esq., Langham Place; A. Henry, M.D., Alfred Street, Bedford Square; J. D. Jones, M.D., Dalston; Henry Lee, Esq., Dover Street; Charles F. J. Lord, Esq., Hampstead; William Newnham, Esq., Farnham, Surrey; William O'Connor, M.D., George Street, Portman Square; R. H. Powell, M.D., Edward Street, Portman Square; John Probert, Esq., New Cavendish Street; Benjamin W. Richardson, Esq., Mortlake, Surrey; Joseph Ridge, M.D., Dorset Square; C. H. F. Routh, M.D., London; R. H. Semple, M.D., Torrington Square; Francis Sibson, M.D., Lower Brook Street; Arthur Stilwell, M.D., Hillingdon, Middlesex; George Stilwell, Esq., Epsom; Joseph Toynbee, Esq., Savile Row; Haynes Walton, Esq., Grosvenor Street; T. Ogier Ward, M.D., Kensington; George Webster, M.D., Dulwich; Joseph Williams, M.D., Tavistock.

tock Square. Several members, beyond the limits of the Branch, were present, including Dr. Spencer Thomson, of Haunton: and some members of the profession not belonging to the Association were likewise present.

Dr. JOSEPH RIDGE moved that Dr. Forbes take the chair. The motion having been seconded by Dr. Powell, was carried by acclamation.

The CHAIRMAN then rose, and thus addressed the meeting:—

Gentlemen, I presume you are all aware of the object of our meeting here to-day, it having been announced by the circulars issued by our temporary Secretary. As we shall go to some practical proceedings, which will show the nature of what we intend carrying on, I need not trouble you with many observations. I will only say, concerning myself, having been a member of the Provincial Association from its origin, and having attended the great majority of its meetings in different parts of England, that I can speak personally of the great pleasure, and the great advantage, I have derived from them. Setting aside the more scientific or professional advantages which one derives from hearing the papers and communications at such meetings, I think there is almost a greater benefit derived by medical men from meeting their brethren in different parts of the country. Everyone, I believe, is convinced, now-a-days, that the more one nation mixes with another, the more their various prejudices are worn off, and the more regard and affection spring up. I believe that is the case in all classes, and not less in our profession than any other; and I have no doubt whatever, that there never has been a meeting of the Provincial Association, or any great meeting of medical men, from which many have not derived decided personal advantages, from feeling that they got acquainted with persons with whom they were anxious to become acquainted, or that they renewed old friendships, and made new ones; in fact, that it was one of those happy holidays which combine utility with pleasure. I think, indeed, that medical men ought to countenance everything that will drag them perforce from their work. Now and then, some of us complain that we have not work enough; but, speaking generally, medical men have work enough, and the great majority have too much work. Conscientious men are, of course, unwilling to resign their work if they can help it; but it becomes a very important matter that there should be a great pressure from without—a great attraction which they cannot resist, and which they are able to tell their friends and patients they cannot resist. I have not the least doubt that the medical men in London, or in the country, in great practice, when they have been forced, or dragged, or have run away to attend the meetings of the Provincial Association in distant parts of England, have spent two or three days, perhaps, in a little tour, and have gone back refreshed, and renewed in strength like giants; and have been thereby enabled to do their work more happily, and to do more good to their patients, than they did before, when their heads were full of cobwebs, which really obscured what ought to be done. (Hear, hear, and a laugh.) There are a thousand other advantages which attend the institution of associations of this kind; and you are aware that, after the first establishment of the main Association, gentlemen found it so pleasant and agreeable, and so useful, that many wished to establish branches, and did so, in their own neighbourhoods. The consequence has been, that new branches have sprung up throughout every part of England. Those branches afford the great benefit to their members of meeting together, of discussing professional subjects, and of seeing their friends. Having the minor opportunities, as it were, nearer home, the members have still the greater advantage, of which they generally avail themselves, of attending the Association at its great meetings. I believe that so far from the branches being found sufficient to satisfy the mass of medical men, they have proved rather a kind of lure to attend the greater meetings. I, for one, think that since the institution of branches, the general meetings have been more numerous attended. I hardly know with whom the idea originated of having a branch near London. I believe it was with Dr. Ward,—whoever it was, it was not with me; I knew nothing about it; I was only asked by some of my friends to assist in organising the movement; but, I suppose one may safely say that the same reasons which have proved that the other local branches are useful, hold good with regard to this. I dare say we shall all agree, that a branch in the neighbourhood of London will have many advantages in various ways. I myself, for one, confess that I have been, the greater part of my professional life, a provincial physician, and perhaps I retain some of my provincial prejudices—and I should be sorry if anything were done by this meeting, or any subsequent meeting, which should destroy in any way the provincial character of the Association. I think if we establish a

Branch here in the neighbourhood of London, we should, I think, be very careful not to make it a mere London Society. I think that we have far too many Societies. We are anxious to attend this, and the other, but really we are bothered and confused by the multiplicity of Societies; therefore it appears to me, that it is not desirable to institute a new Society for London; but if it should be the opinion of the meeting, that it is desirable to form this Branch, and that it would be useful, I cannot help thinking that we should be careful not to make our meetings only in London. There are plenty of places all about London, where the annual meetings might take place; and speaking, at least in name, the London men, I think I might say for my brethren that the majority of them would feel the advantage of getting a day's fresh air in the country, rather than going to the Freemasons' Hall, or the Hanover Square Rooms, to add another murky day to a murky life. However, that will be for the decision of the members hereafter. I only mention my own individual opinion upon the subject. I will now call upon my friend Dr. Ward, to read a statement of what has taken place. I may just in outline say, after some friends consulting together, Dr. Ward sent notice to various gentlemen of a preliminary meeting—that preliminary meeting was held, and it was then decided to be expedient to form a Branch. A temporary Committee was nominated, in order to prepare for a general meeting, and to consider what things should be proposed and submitted to that meeting. The present meeting has now to consider whether it shall form the Branch; and, if so, what special rules and regulations shall be adopted for its governance.

Dr. WARD then detailed the steps which led to the preliminary meeting, and read the proceedings thereat. He stated that the movement had not originated with him individually, but had sprung out of a conversation between him and Dr. Cormack when they met at Oxford last year.

Dr. COWAN, in moving the first resolution, said:—

Mr. Chairman and Gentlemen, the Resolution which I have to propose, is "That a District Branch be established, comprising Middlesex and such parts of the adjoining counties as are not included in any other Branch, under the name of the 'Metropolitan Counties Branch.'" I need scarcely tell you, that I rise at the present moment with very great satisfaction, because I look upon this Meeting as one of the fruits of that agitation which has been going on now, within the limits of the Provincial Association, for a long time. I was myself guilty of a very bold step in doing what I did at the Oxford Meeting; I did it in no revolutionary spirit; it was with no desire to interfere in the slightest degree with an institution which had formerly existed, or with those principles upon which it was founded; but it was with the powerful conviction, that the objects with which we originally started could not be usefully carried out, unless an efficient instrumentality was put in active operation in London. I did it with no spirit of opposition to those who were taking an active part in the Association, but from the conscientious belief that I was doing them the best service in my power, by (if I may use the expression) compelling them to adopt a measure conducive to the object that I had in view. I did it upon that simple principle: I did it at the sacrifice of a good deal of personal feeling. I was quite aware of the difficulty we had to contend with; but, gentlemen, we persevered, and the motion was carried, by which the editorship and the publication of the Journal were removed from Worcester to London. I say, that the manner in which the Journal is now conducted justifies that movement. (Applause.) I would appeal to every member of the profession, and ask if the present publication is not an improvement over that which preceded it. I do not say that with any disparagement. I impute no fault to the Editors of the Journal: I maintain that the deficiency of our previous Journal mainly arose from the deficiency of its opportunities. (Hear, hear.) It was incapable of having an instrumentality at work, to enable it to be useful, and capable of meeting the wants of the profession; and, until we had it under different management and different auspices, it never could have been of use. It was no opposition—it was no disparagement of the gentlemen who laboured for us. We owe our grateful thanks to the members of the profession, more particularly to Sir Charles Hastings, who for so many years has conducted the Association with an energy, a success, and a self-sacrifice which do him the highest honour. My object was to enlarge the Association, and to give them the opportunity of doing that on a larger and more efficient scale, which they had been imperfectly but zealously carrying out up to that moment by a paper which was merely provincial. It was with the view of breaking down the lines of narrow subdivision, and of bringing medical

men in all parts of the kingdom into communication as one body, united by an unselfish principle; of having a vigorous and efficiently-conducted organ belonging to ourselves, by which that intercourse could be kept up, and by which the feelings of the profession could be acted upon by the profession itself. It was the object of the Association so to do; and it was that which it had been doing for the last twenty years. A vast deal of moral good has been accomplished by the working of the Provincial Association: a higher tone of moral feeling has been promoted amongst us, in consequence of those annual meetings and gatherings, and all those operations which have been accomplished by the Provincial Association. We country physicians do not desire to limit it; we do not wish to exclude ourselves from our metropolitan brethren. On the contrary, as soon as circumstances offered, we endeavoured to bring all under the influence of brotherly feeling, and to let them co-operate with us, for the purpose in which they have a common interest, namely, to bring the profession at large under those influences which will conduce to its moral and intellectual welfare. I believe nothing will be more consistent with that purpose than the establishment of efficient Branch Associations. Whatever elevated ideas we may entertain, there must be a *bond fide* something by which we are kept together—not a mere abstract feeling of what is right or what is desirable. It is precisely for this cause we desire to establish this Association, as the only machinery by which we can come personally into contact with the individual members of our profession. It is a necessary part of our instrumentality; without it we never could accomplish what we may determine to do; but with it we have an instrumentality more potent than anything else we could devise. It is true, that we are united to chartered bodies, and subject to a vast number of influences running through our ranks; but I believe that the greatest means of improvement is that of voluntary association on the part of medical men—the profession showing itself as one undivided unity, (scattered, it is true, over a vast distance as to space, and occupied in many different manners,) each member having the feeling, “I am a member of a united body; that body, I believe, has common moral purposes, common intellectual and scientific purposes; and the more I identify myself with that body, the more I partake of that spirit which is consistent with the welfare of the body at large, just in that proportion am I reaping that benefit I ought to desire to receive from it, and imparting that which as a profession we ought to seek equally amongst ourselves.” We shall never do better for the profession than by associating; and I do trust that all notions of *provincial* and *metropolitan* will be entirely excluded from our consideration at the present moment. Let us feel that every legitimate practitioner of medicine, every man whose moral character will bear examination, shall be welcomed as a member of our Institution; that we have nothing to exclude but that which is inconsistent with our highest and best interests as members of society, and of an honourable profession. I do myself feel strongly upon this subject; I am anxious that the profession should feel that there is a work which we have yet but imperfectly performed; that we are capable of doing more for ourselves than our chartered institutions can do for us; and let us take care that we do that which is consistent with our lasting and enduring welfare. It is only in proportion as we rise above the selfish element, and pass into principles which have for their purpose the general good, that we elevate ourselves in the moral atmosphere, and diffuse that moral atmosphere amongst those with whom we have the privilege of acting. I do trust that we shall extend our operations very much indeed beyond what we have yet contemplated. I hope that the funds of the Association, derived from the influx of new members (which is at present so actively going on), will give us the opportunity of doing vastly more than we have even intended to do. They will be a source of power within our hands; and, if directed to carry on the best interest of our profession, will be an incalculable boon to us all, by extending the circulation and maintaining the efficiency of the Journal. I hope that soon there will not be a member of the profession who will be excluded from those benefits. I believe that the Metropolitan Counties Branch will be the means of accomplishing that which the Association is capable of effecting in London more than anywhere else. From the fact of the numbers congregated in a limited space, there are opportunities of benefitting the profession at large in a higher degree than any other branch of the Association possesses; and we must feel that we have an arm in this branch of the Association,—not a metropolitan arm in the strict sense of the word, under the circumstances in which you practise, and in which you are placed here, but an arm which can accomplish more for the profession

as a body, than any other of our branches can hope to do. If our design is carried out heartily and unitedly, it will accomplish all we can reasonably wish. I feel sure that this Branch has been rightly founded, by embracing along with the metropolis places at convenient railway distances, such as the town in which I reside; and that the results will be consistent with the welfare of us all. I therefore most sincerely and cordially propose that the Metropolitan Counties Branch be proceeded with: and I wish it every prosperity.

Mr. HAYNES WALTON, of London, seconded the resolution.

Mr. STILWELL (of Epsom) said: Gentlemen, may I take the liberty of making a few remarks upon that which I consider hitherto to have been the weak point of the Association, namely, that a due care has not been bestowed upon the welfare of the general practitioner? My attention was forcibly directed to this subject in the late attempt to obtain an Act of Parliament to form the druggists into a profession. This attempt received support from influential members of the profession, and had it not been for Dr. Webster and a few other private individuals, a law would have passed, which, in my opinion, would have greatly injured the general practitioners throughout the country, and would have gradually, but most certainly, have introduced a lower grade of medical practitioners, though the contrary has been the aim of the profession for the last fifty years. When such an attempt at legislation as that to which I have alluded, was made, the profession was justified in expecting that its interest would have been cared for and watched over by their own organ;—instead of which, the Council and editors of the Journal took no part beyond admitting a few letters, coupled with some passing remarks of no effect. It is to be hoped that the Council and the present editor will not confine their doings to making known the sentiments of the *élite* of the profession alone, but that they will, for the future, take such responsible care of the welfare of the general practitioners as will give them confidence, and induce them to become and continue members of this Association.

The CHAIRMAN scarcely thought the remarks of the last speaker pertinent to the motion before the meeting, the object of the meeting being to decide whether there should be a Branch established or not.

Dr. DAVIES, of Hertford, observed that many of the practitioners of Hertfordshire would gladly join the Metropolitan Branch, and begged to suggest that it should extend to the limits of the Home Circuit.

Dr. WARD said, that it was for the meeting to define the limits of the Branch, and from the tenor of a reply received by him on the previous day (in answer to an application from the Provisional Committee), the Worcester Council stated that those limits might extend to any width, inasmuch as gentlemen were perfectly at liberty to belong to more than one Branch.

Mr. BOWLING (of Hammersmith) had no wish to interfere with any other Branch; but in Surrey and Kent there were many practitioners who belonged to no Branch, and therefore this Branch would be open to them as more convenient than the South Eastern.

Dr. POWELL observed, that from his experience in other societies, it struck him that a little difficulty would occur in convening meetings, unless the limits were clearly defined in such a manner as to prevent any clashing or imputation of neglect. He thought it was important that the meeting should to-day define what were to be the geographical limits of this Branch.

Dr. CORMACK thought it would be better to say “Metropolitan Counties”; which, after discussion, was agreed to.

Mr. BOWLING hoped the meeting would avoid anything which would be calculated to excite the jealousy of neighbouring Branches. It was held out at Oxford, that the Journal was to be diverted from the provinces, in order to make it a mere metropolitan journal; but that never was the intention of the Oxford majority.

Dr. DAVIES asked whether the limits of the other Branches were defined?

The CHAIRMAN believed not at all, except in a general way; the counties were so and so. He spoke, however, only from his general knowledge. At some future day, he foresaw that there would arise the great question which Dr. Cowan had shadowed forth. His (Dr. Cowan's) idea was, that what had hitherto been the Provincial Medical and Surgical Association, should ultimately become the Medical Association of England. (Hear, hear.) The adoption of such a proposition might probably lead to the greatest possible advantages. He believed that the Provincial Medical and Surgical Association had laboured under a great disadvantage, from being merely provincial. It was just possible, that at some future time it might be wise to consider, whether this Provincial Medical Association should no

be converted into an association for all England and Scotland.

Dr. STILWELL (of Hillingdon) knew that there was some jealousy existing with regard to the influence which a Metropolitan Branch might eventually exercise. Although the idea of an Association for all England and Scotland was undoubtedly a grand idea, yet at present the Association retained a provincial character, and he should be exceedingly sorry that that character should be lost.

The Rules, which had been prepared by the Provisional Committee, were then submitted to the meeting by Dr. Ward.

Some discussion ensued, as to the modification of some of the rules, in which Drs. WEBSTER of Dulwich, CORMACK of Putney, DAVIES of Hertford, Drs. DANIELL, GRIFFITH, POWELL, and O'CONNOR, of London, and Messrs. ANCELL of London, BOWLING, of Hammersmith, and CARTER of Hadley, took part; in the course of which,

Dr. CORMACK moved, and Dr. WEBSTER seconded, That the rules, as amended, be adopted as the rules of this Branch Association; and that a small Committee be appointed, to report to the first Annual Meeting upon any improvements which they may be able to suggest.

Dr. SIBSON moved, as an amendment, and Dr. O'CONNOR seconded, That the rules now agreed to, be adopted as the rules of this Branch; and that they be referred to the Council for revision.

The original motion being withdrawn, Dr. Sibson's amendment was carried.

Dr. WEBSTER moved, and Dr. SIBSON seconded the resolution, That Dr. FORBES be appointed President, which was carried with great applause.

After some discussion, it was determined that the President should continue in office until the second Annual Meeting.

Mr. BOWLING moved, and Dr. DANIELL seconded, that JOHN PROPERT, Esq., be the President elect.

Dr. COTTON moved, and Dr. WARD seconded, that JOSEPH TOYNBEE, Esq., be appointed Treasurer for the Branch.

Dr. CORMACK moved, and Dr. GRIFFITH seconded, that Dr. OGIER WARD be appointed Secretary.

Mr. TOYNBEE moved, and Dr. O'CONNOR seconded, that the following gentlemen form the ordinary Council of the Association,—to remain in office like the other office-bearers, until the second Annual Meeting:—

HENRY ANCELL, Esq., 3, Norfolk Crescent.

JOHN BOWLING, Esq., Hammersmith.

WM. BOWMAN, Esq., London.

C. T. CARTER, Esq., Hadley.

JOHN CONOLLY, M.D., Hanwell.

J. R. CORMACK, M.D., Putney.

CHAS. COWAN, M.D., Reading.

W. H. EVANS, Esq., St. Alban's.

GEO. GRANT, M.D., Richmond.

THOS. HEWLETT, Esq., Harrow.

CHARLES F. J. LORD, Esq.,

Hampstead.

R. H. SEMPLE, M.D., London.

FRANCIS SIBSON, M.D., London.

JAS. STILWELL, Esq., Uxbridge.

GEO. WEBSTER, M.D., Dulwich.

Dr. CORMACK moved, and Dr. DANIELL seconded, that the subscription of members be due annually on the first of January. It had been previously arranged that the annual subscription to the Branch should be 2s. 6d.

Mr. B. W. RICHARDSON moved, and Dr. WEBSTER seconded, that the thanks of this Meeting be given to Dr. FORBES, for his able conduct in presiding on this occasion.

The CHAIRMAN briefly responded.

The SECRETARY proceeded to enrol members and receive subscriptions.

EDITOR'S LETTER BOX.

CHOLERA IN THE BAHAMAS.

REMARKS BY DR. CHIPMAN, COMMUNICATED BY DR. COGSWELL TO THE EDITOR.

SIR,—The following extract from a letter I have just received from the Hon. Dr. Chipman, of Nassau, New Providence, Bahamas, appears to be worthy of publication. It relates to the cholera as prevailing epidemically in those delightful, and usually healthy islands. The letter is dated, Nassau, Dec. 7th, 1852.

Your obedient servant,

C. COGSWELL.

Bernard Street, Russell Square, London,
Jan. 11th, 1853.

"Within the past ten weeks, the cholera has been committing fearful ravages in this and the adjacent islands of the Bahamas. On Saturday, the 18th September, the disease made its appearance in a low swampy locality, in the eastern suburbs of Nassau, and almost simultaneously in the eastern district, about a quarter of a mile farther east, in the vicinity of a jungle of bush, formed in the rear of a long line of houses facing the upper harbour, where the fishery and wrecking vessels and boats, are kept at anchor, fronting the houses of their owners. In a day or two afterwards, the epidemic showed itself in an African settlement to the S.W. of Nassau, upwards of two miles distant from the jungle referred to at the E. of the town, and very quickly afterwards, it manifested itself everywhere, where filth and other localising causes invited it. In the two months commencing the 18th September, and ending the 19th November, ult., eight hundred people out of a population of about nine thousand died, the mortality being chiefly confined to the poorer classes. Ordinarily, those in comfortable circumstances escaped. There were only four medical practitioners in Nassau, to meet this terrible epidemic, and one of them had the garrison to attend, the P.M.O. being ill and obliged to leave for England. How we got through with the work, God only knows, but we were wonderfully preserved during a most arduous duty, which literally occupied us night and day. I am happy to say that the disease is rapidly declining, the deaths being now about six or seven per week, and from the decrease of the diarrhoea, we may cherish the hope that in a few days it may cease altogether. At several of the out islands, especially at Harbour island, and Abaco, the epidemic still rages, and is carrying off several daily."

[We would be glad to receive from Dr. Chipman any information bearing upon the question of the importation of the disease, and its propagation among the different islands through the medium of maritime intercourse. It would likewise be interesting to learn whether any peculiarity has been lately observed in the meteorological condition of the Bahamas.]

MR. HARRINSON'S CASE OF UTERINE HÆMORRHAGE.

LETTER FROM PROFESSOR MURPHY TO THE EDITOR.

SIR,—In the case described by Mr. HARRINSON, at p. 11 of the last number of the ASSOCIATION JOURNAL, he says:—"No writer, that I can find, has described one exactly corresponding, and some authors do not even name the possibility of such an occurrence." He then mentions, in evidence of the correctness of his statement, R. Lee, Copeman, Churchill, Ramsbotham, and Blundell, as authors who do not give an account of similar cases. He has, however, omitted me: I have fully described the occurrence to which Mr. Harrinson drew attention, at p. 325 of my Lectures on Midwifery, where I have likewise quoted two cases to the point from Hardy and M'Clintock.

I remain, etc.

EDWARD MURPHY, M.D.

12, Henrietta Street, Cavendish Square,
January 10, 1853.

HOMŒOPATHY IN THE EDINBURGH SCHOOL OF MEDICINE.

LETTER TO THE EDITOR.

SIR,—It is very important that you should fearlessly make known, from time to time, the bad state of certain medical schools, so that members of the Association may be able (to the extent of their influence) to prevent their young friends from resorting to them. For example, it seems to be forgotten that Dr. Henderson, a sort of a homœopath, still fills the chair of pathology in the University of Edinburgh, and that among the students medical heresies are thus widely promulgated.

Your obedient servant,

PATER.

January 12th, 1853.

[The condition of the Edinburgh University School of Medicine is not generally understood. It never was in a better state. Dr. Henderson cannot be got rid of; which is to be regretted: but he has little power of doing mischief, having nothing to do with clinical teaching. As regards the students, we believe that they are as a body uncorrupted; and in proof of this, we have been informed, that the rising talent of the profession, as represented by the Royal Medical Society, lately refused to place on their library shelves a presentation copy of a work by a homœopathist. Can any member of the Society corroborate this statement and furnish the particulars?]

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. III.

LONDON: FRIDAY EVENING, JANUARY 21, 1853.

NEW SERIES.

PRACTICAL APPLICATIONS OF A KNOWLEDGE OF MEDICAL HISTORY.

In a recent number (January 7th, p. 4) we promised to return to the subject of Medical History, and to urge its claims as a practically useful study. We write at this time in fulfilment of that promise.

In the first place, then, we would observe, that information on subjects pertaining to the records of medical science in days of yore, would greatly assist the student in forming an accurate judgment as to the worth of many of those remedial measures which modern teaching places at his command. For, although it must be granted that, in the progress of the healing art, extraordinary revolutions have taken place as regards the treatment of disease, it must also be admitted that numerous important points of practice still in full use have for their origins very ancient dates. Let us, in proof of this assertion, note down a few very ancient remedial measures; premising, however, that the subjoined list is written without any regard to arrangement, and that the various forms of treatment named include only those which flow from our remembrance as we write—therefore very far from all that might have been given; and that every remedy which is introduced was known and used previous to the sixth century of the present era.

The list will run as follows. Frictions; baths; fomentations; poultices; vesications. The abstraction of blood—by venesection, arteriotomy, cupping, or leeching. The arresting of hæmorrhages—by ligature of vessels,* torsion, application of pressure, cold, cauteries, or styptics. The use of enemata, vomits, purges, diuretics, tonics, narcotics, etc. The operations of tracheotomy, lithotomy, of opening abscesses, of removal of nasal polypus, and of extraction of teeth; the fixing of loose teeth by bands, the reduction of fractures, and the employment of the splint, the bandage, and the sling; the reduction of dislocations, and the use of the pulley for that purpose; the extraction of cataract, the removal of foreign bodies from wounds, the application of sutures to wounds, and of stimulating substances to indolent sores; the treatment of aneurism by ligature and by pressure; the laying open of fistulous sores; the insertion of issues; the administration of such valuable medicines as opium, henbane, hemlock, galbanum, gentian, sulphur, copper, mercury, lead, croton-oil, castor-oil, squills, colocynth, and alum; and, lastly, the employment of the most valuable rules regarding exercise, diet, and cleanliness.

But it may be asked—Did not the ancient administrators of the above-named means of cure often use them most injudiciously and absurdly? In all probability they did so on some occasions; and the probability is not less

that we, the prescribers of to-day (aye, the wisest of us), frequently employ the same remedies in a most absurd and injudicious manner. The ancient physicians used the remedies they possessed to the best of their abilities: modern physicians can do no more.

The ancients coupled superstition with their means of cure, cries some objector! So do the moderns, is our unhesitating response; and we only require to see ourselves from the distance of some fifty or a hundred years, to be made conscious of the fact. Superstition! why what, after all, is superstition? This, and nothing else,—man observing the accomplishment of a fact, and assigning a cause or causes for that accomplishment, which afterwards are proved to have had little, perhaps no connexion with the fact. Superstition can never cease whilst man is fallible. It is interesting, moreover, to observe how fully the history of medicine bears out this view of the subject. At the bottom of the wildest superstition of ancient physic, there was often buried a great truth; a truth, indeed, which formed in the first periods the invisible agency on which the superstition itself was nourished; which afterwards, in a further state of transition, presented itself to some gifted eye in a degree separate from, and higher than the superstition; and which eventually became manifest to the eye universal, untrammelled altogether, and in its pure and naked character.

Dr. Paris, in one part of his *Pharmacologia*, gives an admirable illustration of the truth we here enunciate, in the narration of the wonders effected in the curing of wounds, by the use of the sympathetic powder of Sir Kenelm Digby: "Whenever a wound had been inflicted, this powder was applied to the weapon that had inflicted it, which was, moreover, covered with ointment, and dressed two or three times a day. The wound itself, in the meantime, was directed to be brought together, and carefully bound up with clean linen rags, but, *above all, to be let alone* for seven days, at the end of which period the bandages were removed, when the wound was generally found perfectly united." In this instance, a natural cure was of course effected, and "the result," as Dr. Paris observes, "beyond all doubt, furnished the first hint which led surgeons to the improved practice of healing wounds by what is technically called *the first intention*."*

Again, the ancient prescribers not unfrequently used very useful modern remedies, only after a more primitive formula, and under a different name. Thus, the Editor of this Journal, in his essay on Creasote (Edin. 1836), has proved beyond dispute, that the preparations of wood-tar, that is, creasote in its original shape, have been used as medicinal substances from the earliest times; and that, too, for the very same purposes for which creasote is now prescribed. In like manner, also, iodine has long been employed for bronchocele, in the form of burnt sponge. So that, in short,

* The credit of introducing the use of the ligature for the arresting of hæmorrhage, has usually been given to Ambroise Paré, who was born early in the sixteenth century, and died in 1590. Joseph Warner, F.R.S., says that Paré believed himself inspired when he discovered the use of the ligature.—*Cases in Surgery*, 1764. The discovery, however, was made long previous to the time of Paré.—*Vide Celsus*, lib. v. cap. xxvi. sect. xxi. Aëtius also describes the use of the ligature for the cure of aneurism.

* Traces of this superstition still linger in some parts of England. The writer of the present article well remembers that having in his childhood injured his foot with the tine of a fork, he was recommended by a kind old dame to do nothing to the wound itself, but to be most particular in keeping the fork perfectly bright, for a week at least.

many modern medicines are "to the medical world" (we employ Dr. Cormack's words) "old friends unmasked."

The mention of these facts will, we think, satisfy the thoughtful reader of the truth of the remarks with which we commenced this article, since he will see that the Æsculapian disciple can in no way form a better estimate of the value of any special point of practice, than by tracing back the history of the practice, ascertaining who was its discoverer, the facts that led to the discovery, and the importance that has been attached to it by competent observers in succeeding times.

But, leaving the subject of remedies, we are not afraid to assert that in the ancient, unread, and voluminous writings of our medical fathers, many a precious observation and fact, on the nature and cause of diseases, lies hidden and neglected.

And here another thought breaks upon us, which we must reduce to syllable and sentence. It is scarcely necessary to say, that the world at this time is inundated with books. The stream of literature, which flowed on so quietly last century, is in this age a wild and overflowing sea. Book-making and gold-digging are the two rival manias of the age, and the profession of medicine is neither the least nor the last to show its attachment to the book-making mania. The tyro now, who for thrice nine months has gossiped at a hospital, and enriched himself with those medical Vedas, *A Grinder's Notes*, takes his diploma, and feels it at once a duty both to himself and the public, to write a book. This is bad enough certainly, but it is not the worst. The quill of the young writer tickles unpleasantly the noses of older men, who "straight dream" that, if their juniors attack the public even with bad powder, it will never do for them to rest contented with their old-fashioned bows and arrows; and so there rises forthwith another class of writers, who parade an experience which never interested them—who advance as a novelty anything which they, in their limited capacities, have not heard of before; and who write, in fine, merely because they think, that not "to do," is "to die". Thus the medical press is always in labour, and allegorical mice are constantly being eliminated, with the breeding rapidity of real mice in harvest time. Under these observations, however, "let galled jades" only "wincede". We know that at the present time, more than ever, numbers of earnest and truth-loving writers are at work; and to these, one and all, eminent and obscure, we offer our sincere tribute of love and respect. Nay, we have cause to admire the spirit of activity and enterprise which calls forth unprofitable works. Our sorrow is, that so much of the same spirit should be vilely squandered; and we would hold up with joy any plan that would turn this lost labour to better account. In the introduction of the study of Medical History into our system of education, such a plan offers itself. In this study, a field is opened, on which any number of minds may labour for an unlimited time, with usefulness and honour. The pangs of the mere copyist would there be legitimately quieted, in reproducing the ideas of other men, pure from corruptions of his own. The steady plodder would find employment suitable to his tastes, and worthy of his modest aspirations. Nor need the child of genius despise the prosecution of Medico-Historical investigations; for where is true genius more required than in solving the vast problems of history? And would it not be a high honour to be recognized by scholars as a medical Macaulay?

EXAMINATIONS REAL, NOT VERBAL.

GREAT improvements and great discoveries, when known, seem to be so simple and obvious, that the wonder to all is that they were never adopted or found out before. And there are few more simple and obvious improvements, and none perhaps of more vital importance, than the addition of *real to verbal* examinations, by the Examining Board of the University of London. A century hence, the mode in which students are now mostly educated for medical and surgical practice, will, we trust, hardly be credited. The plan hitherto has consisted in crowded lecture-rooms, while the attendance in dissecting-rooms, botanic gardens, chemical laboratories, and the wards of hospitals has been miserably scanty. Young men have assiduously worked at books in their own rooms and under grinders, and have let slip the most precious opportunities of learning their profession. They have plied themselves with the thoughts, opinions, and acts of other men, without gaining the power of thinking or of observing at all. Who does not look back with a sigh, or with a more bitter feeling, at a system which compelled him to go from lecture-room to lecture-room, to hear for the most part *words*, in order that he might pass an examination of *words*;—the one to fit him, and the other to convince the world that he was fitted, to practise, not a language, but a practical art and a science dealing with *things*? The whole system—teaching, grinding, and examining—was exactly calculated to make him believe that he had only to commit to memory a certain number of words, in order to cure disease: a most cruel treatment, nicely calculated to raise his hopes in order to disappoint them; to foster all his conceits at his acquirements, in order to shew the falseness of their foundation. He was sent away with prizes and medals and parchments, which proved, not that he had in any way mastered his art, but that he knew how to talk about it. Now the fault which lies at the very bottom of this system, and on which it rests, is the examination at the end. Improve that, and the other must correct itself. Examine the candidates in *things*, and not in *words*, and they must know the things and not merely the words representing them. Test anatomy by dissection, and the dissecting-rooms will be well attended. Test chemistry in the laboratory, and that will be the place of chemical study. Test surgery and medicine by the actual examination of patients, and the bedsides will be surrounded. This plan has been commenced by the University of London, and must sooner or later be followed by the other Examining Boards; and we feel convinced that the actual improvement in medical education will be rendered greater by this single alteration, than by any new curriculum, however comprehensive.

We will conclude with two instances of the working of the present system.

Two students competed for a botanical prize. One has since proved himself an original botanist of the highest accomplishments. At that time his knowledge of plants was marvellous. He could tell any species, name it, and give the natural order, even in Kew gardens, and his acquaintance with structural botany was great. The other knew something of the botany of his district, and little more, but very carefully got up by notes the lectures they were attending; and although not fit to hold a candle to the other, he ran him so hard in a written examination, as to be within a few figures of gaining the highest prize. He had sufficient self-knowledge to be glad that he did not.

In the second instance, the very worst house-surgeon inflicted on a public hospital, was the highest prize-man in his college, and was elected on the strength of his prizes. His abilities were excellent; but he had devoted with diligence all his powers to the acquisition of words from books, and broke down in an appointment which demanded a knowledge of things.

The system has been to blame, not the student; and we thank the University of London for having begun prominently to adopt a more scientific mode of examination, and for thus giving us the promise of a more capable set of junior practitioners.

ORIGINAL COMMUNICATIONS.

ON THE NATURE AND CAUSES OF THE PHYSIOLOGICAL PHENOMENA

COMPRISED IN THE TERM "MOUNTAIN SICKNESS"; MORE ESPECIALLY AS EXPERIENCED AMONG THE HIGHER ALPS.

By STANHOPE TEMPLEMAN SPEER, M.D.

It is, I believe, very generally admitted, that when an individual habitually residing at a moderate elevation above the level of the sea, attains in a short space of time a considerable altitude above such level, he will in all probability experience certain deviations from his ordinary condition of health, sufficiently marked to constitute, for the time being, a state of actual indisposition, if not of disorder.

Now, in examining the narratives of those who have been most qualified from personal experience to investigate the subject, we find much discrepancy existing; not merely in relation to the nature and intensity of the phenomena in question, but even as regards their very existence.

Having however experienced on several occasions, to a certain extent, the effects of a rarefied atmosphere, upon some of the loftiest Pennine Alps, I venture to offer a cursory view of the subject, in reply to the three following queries, which it naturally suggests.—1st. As to the actual occurrence and nature of the physiological phenomena alleged to be experienced at great heights? 2nd. Are these felt by all persons alike and at the same height? 3rd. What are the causes, and whence the explanation, of such phenomena?

A reply to the first of these inquiries, that which refers to the actual existence of an abnormal condition of the body at a great elevation, is to be sought for by reference to the somewhat scattered accounts here and there afforded by those, who, whether from curiosity or for scientific purposes, have scaled the loftiest summits of the great mountain chains of Asia, America, and Europe.

It need scarcely be said, that the information to be derived from those in whom somewhat more than curiosity constitutes the stimulus of enterprise, is by far the most valuable; not but that the courageous though unreflecting explorer of the Higher Alps may occasionally be heard to complain on his return, of having experienced certain disagreeable sensations to which he had hitherto been a stranger; the rapid subsidence of which however, on regaining the usual level, would render them (in his estimation) merely worthy of a passing remark.

Various circumstances combine to produce that diversity of opinion which is to be met with, relative to the phenomena in question. In the majority of instances, the ascent of a lofty mountain is undertaken as a pleasure excursion without any definite object; it may have been prompted by a love of *édelt*, or, what is more to be admired, by a thirst after the beauties of nature, and a wish, in spite of danger and peril, to approach as near as possible to her noblest works; and as a rule, with but few exceptions, the feelings elicited on such occasions are totally opposed to a

careful and impartial examination of facts, for sensations, which under every-day circumstances might be dwelt upon in detail, are now almost disregarded and absorbed in sentiments of a higher and less corporeal nature.

Another cause for the above-mentioned discrepancy relative to the subject in question, arises from the peculiar circumstances under which the ascent of a lofty mountain is usually made. The majority of those who undertake such an enterprise, are comparative strangers to mountain scenery and mountain exercise. They spend a day or two at the foot of these mighty masses, and forthwith proceed at once to attempt to scale the object of their ambition. Here everything is novelty of the highest order. The succession of wonder-striking scenes which they now behold, it may be for the first time, the rapidity with which marvel succeeds marvel, the bewildering sensation experienced, when first encountering those extraordinary objects of which no description can give an adequate idea, the glaciers, the feeling of dread occasioned by the ghastly aspect of their gaping crevices, the thrilling sensation momentarily produced by the dreaded sound of the falling avalanche, and last, not least, the all-absorbing sentiment of triumph, resulting from the safe and successful termination of an attempt, the accomplishment of which may have been, for some time previous, the object of thoughts by day and dreams by night; these circumstances, I repeat, are sufficient to burden and embarrass the mental perceptions of the tourist. His memory becomes crowded with a variety of souvenirs and facts, which ere long, by their very number and intensity, destroy one another. On his return to the ordinary dull routine of life, the thrilling events of the past stand out in still bolder relief to the monotony of the present: his imagination outruns his bewildered memory, and he pictures to himself and others, scenes and circumstances which he may conceive to be correct, but which not unfrequently, upon close inspection, bear the evident imprint of fancy preponderating over fact. Viewed in this light, it can be no matter of surprise, that he should either forget the corporeal annoyances he may have experienced, or that he should make light of them, and throw doubts on the veracity of others more keenly susceptible to physical impressions than himself, and more bent upon the calm appreciation of certain facts, than upon the enjoyment of the most exciting gratification. It is not unreasonable to suppose that, in the case of many Alpine ascents, the individual (unless completely prostrated), resembles the soldier on the field of battle, the pain of whose wound, if not sufficient to disable him, is unperceived until the engagement be at an end; so with the Alpine tourist, his physical sensations, unless strongly marked, being swallowed up in the interest of the moment, are thus not only disregarded during their actual existence, but from their rapid subsidence on returning to an ordinary level, are excluded from a prominent place in his after recollections.

In the records, however, of such travellers as Humboldt, Boussingault, d'Orbigny, Zumstein, Saussure, Pictet, and others, there are to be found many valuable and accurate references to the sensations experienced at great heights, more especially among the Andes and the Himalaya; for while the region of the higher Alps is that to which the present remarks have chief reference, the superior elevation of the two afore-mentioned chains would naturally lead us to suppose, that the attempt to scale their loftiest summits should have afforded marked examples of those functional modifications to which I have alluded.

The celebrated Humboldt ascended the peak of Teneriffe, without experiencing dyspnoea or any unpleasant sensation whatever. This was also the case with his travelling companion. When among the Andes he determined to attempt the ascent of Chimborazo, one of the loftiest of the whole chain: he had previously resided, for a certain length of time, on the table-land of Quito; from thence he proceeded with Bompland and Montufar to the plain of Tapia, and having slept at Calpi at an elevation of 9,471 feet above the sea level, they began to surmount the inferior terraces of

which the mountain is composed; at a height of 13,155 French feet, they saw snow that had lately fallen, and at length attained a height of 16,724 feet without material inconvenience. The Indians, however, who accompanied Humboldt, had, with one exception, turned back at a height of 15,201 feet, alleging that they suffered far more than their employer. The following is Humboldt's description of the sensations which he at this moment perceived: he says, "after attaining an altitude of 16,724 feet above the level of the sea, we continued to ascend for another hour, during which we all became by degrees much distressed: a constant desire to vomit, together with vertigo, were the most prominent symptoms, and proved far more trying than the difficulty of breathing which we likewise suffered from. An inhabitant of San Juan who had accompanied us, although robust, was still more affected. In all, the blood started from the lips and gums, while the conjunctiva, covering the eye-ball, was in each of us distended with blood. On the Antisana, Montufar likewise experienced a certain amount of hæmorrhage from the gums. All these phenomena however differ essentially, according to the age and previous habits of the individual, to the thinness of his skin, to the amount of muscular exercise to which he has been accustomed, etc. They however serve to afford, each one, a sort of measure of the rarefaction of the air, and of the altitude attained. In the Andes, they manifest themselves when the barometer stands at from 0 min. 379, to 0 min. 428. We continued to ascend for three hours and a half beyond the limits of perpetual congelation, and, in spite of the rarity of the atmosphere, we had not found it necessary to take any repose." The greatest height which Humboldt at length reached was 17,634 feet.

In traversing that portion of the Andes which separates Arica de la Paz from upper Peru, M. d'Orbigny first perceived the effects of diminished atmospheric pressure; this was at a height of 13,500 feet, upon the summit of Cachun. On the Col de Tacora, which is still more lofty, though within the limits of perpetual snow, he suffered from a violent and constant headache, together with considerable distress in breathing, and the whole party were unable to proceed upwards of thirty yards without halting. M. d'Orbigny thus speaks of his sensations upon this occasion. "I felt in an extreme degree the rarefaction of the atmosphere, in the shape of violent pain about the temples, together with those peculiar sensations at the præcordia, which characterise sea-sickness. I breathed likewise with difficulty; on making the slightest movement, I experienced violent palpitation, and a general uneasiness and depression, to overcome which all attempts were unavailing. Towards evening a smart fit of epistaxis produced temporary relief; I nevertheless passed a miserable night, inasmuch as I suffered, in addition, from exposure to a sharp biting cold, without shelter." During the few days which he of necessity spent at this elevation, the same symptoms continued with unmitigated severity.

The guides who accompanied D'Orbigny, informed him that they had lately conducted a Spaniard across the chain by the same pass, that he was so susceptible to the rarefaction of the atmosphere, as to have suffered on the first day of their journey from most alarming symptoms, and that being unable to continue his journey, or even to return, had died on the second day, without any alleviation of his sufferings. They also related several other instances in which the travellers with whom they had crossed the Andes, had suffered most severely from what they designated as the "*soroche*". This term, given by these men to what may be denominated mountain sickness, is derived from the fact of their attributing the effects which are in reality produced by the rarefaction of the atmosphere, to the emanations arising from mines of antimony, which they believe to exist in the neighbourhood: the Spanish term for antimony being *soroche*.*

The traveller Jacquemont, speaking of the ascent of a portion of the Himalaya range, says, that at an elevation

of 7,845 French feet above the sea level, he perceived nothing unpleasant; but that after ascending for two hours above the limits of perpetual congelation, it was found extremely difficult to traverse the soft snow, at a height where "the rarefaction of the air rendered the respiration difficult and hurried, and necessitated a halt at about every thirty paces." Jacquemont here refers to the case of an English physician, who in the same locality suffered severely, and lost several of his suite from similar causes; Jacquemont himself, having spent some time at various heights on the range of the Himalaya, appears to have at length become thoroughly habituated to the effects of a rarefied atmosphere.*

Two English writers likewise, Moocroft and Fraser, agree as to the physiological phenomena observed on the Himalaya. The former, in ascending the Niti Ghati, suffered from a feeling of fulness in the head and giddiness, and fearing an apoplectic stroke, lay down; this produced a temporary alleviation of the symptoms, but all attempts to proceed were fruitless, inasmuch as they immediately recurred with increased severity. In descending, he suffered but little; but on encamping for the night and retiring to rest, he had a return of the attack, together with much oppression of the chest, relieved only by taking deep inspirations.†

In *Fraser's Journal* we find a confirmation of the preceding account. At a height of 11,300 feet upon the Col de Bamsourou in the same range, the writer felt a trembling of the knees, with nausea and vomiting. His retinæ likewise suffered, some in one way, some in another; one complained of severe pain in the head, another of oppression of the chest, a third of gastric derangement. Many of them were overcome with sleep, and could scarce be kept awake for a moment.

To revert to the writings of M. d'Orbigny, it appears that in the vicinity of Cocha Bamba, at a height of nearly 15,000 feet, he experienced great difficulty of breathing. At La Paz, 11,151 feet above the sea, he felt suffocated in his room at night; at the slightest ascent, he was forced to stop every ten paces from the occurrence of palpitation and dyspnoea. He could neither converse with rapidity, nor indulge in the natural dances of the country, without being obliged almost immediately to desist, and this from similar causes. These sensations lasted during his entire residence at La Paz.

La Condamine and his fellow-traveller Bouguer have also furnished some details relative to the sensations which they experienced among the Andes; and although, as was previously stated, their appreciation of them differs somewhat from the previous accounts of Humboldt and d'Orbigny. Bouguer and La Condamine ascended the Pinchincha, one of the loftiest of the Peruvian Andes, in company with a Spaniard. The latter was seized during the ascent with a strong syncope tendency, which rendered it necessary to remove him to a neighbouring cave or grotto, where he passed the night. La Condamine, however, does not appear to have suffered much, for, at an elevation of 14,750 feet, he and his companion constructed a tent, where they remained for three weeks, during which time he experienced no difficulty of breathing, but merely a slight bleeding from the gums, attributed by Bouguer to a scorbutic condition of the blood, the result of cold.

The latter traveller, speaking of the sensations experienced on this occasion by his attendants and himself, says: "At first we found ourselves much annoyed by the rarefaction of the air, those among us whose lungs were rather delicate, felt the difference proportionally greater, and were even liable to slight attacks of hæmorrhage. As regards myself, I cannot affirm that the inconvenience became greater, when (at a subsequent period) we attained an increased elevation. This probably arose from the fact of having become inured to the locality and its atmosphere. Some of our party, however, when in the act of ascending, were seized with sudden syncope, together with nausea and

* D'Orbigny, *Travels in South America*, vol. ii; and Lepileur, *Phénomènes Physiologiques*, etc.

* Jacquemont, *Correspondence*, vol. i, p. 266-273.

† *Asiatic Researches*, vol. xii.

vomiting. I conceive, however, that these symptoms were rather the result of lassitude, in proof of which I may remark that they were not felt if the ascent were made on horseback; nor on attaining the summit, where nevertheless the air must have been still more rarefied. I do not however deny that this rarefaction materially augmented the sense of fatigue and exhaustion, inasmuch as the respiration became much embarrassed upon making the slightest exertion.

In his attempt to reach the summit of Chimborazo, M. Bousisingault experienced the effects of the rarefaction of the atmosphere to such a degree, as to be under the necessity of halting after every three or four paces.

Additional references might here be made; but it is sufficiently evident, from the above extracts, that those travellers who have ascended the higher peaks and passes of the Andes and the Himalaya mountains, have with few exceptions experienced sensations to which they were strangers when at an ordinary level; and that these have varied in character and degree in different individuals, according to circumstances; thus explaining any apparent discrepancy in the various accounts given, as to the intensity of such phenomena and to the exact height at which they occur. It is clear moreover from these narratives, that absolute accuracy on such points was not regarded as a *sine quâ non*; a minute attention to their own individual sensations forming certainly no part of the objects which such intrepid explorers as Humboldt, Bousisingault, etc., had in view.

It is, therefore, chiefly among the higher Alps that the phenomena, attendant upon a considerable elevation above the level of the sea, have been perceived and described with accuracy; and by none more fully than by De Saussure, in his celebrated *Voyages dans les Alpes*.

Before attempting to scale the loftiest of European mountains, De Saussure in 1778 ascended the Buet, in company with Professor Pictet. This mountain is the highest of a chain which runs parallel to that of the Mont Blanc, and is about 10,000 feet above the level of the sea. In his account of the expedition, he mentions the fact of having experienced a great degree of muscular debility and exhaustion, rapidly subsiding, however, upon abstaining from the exertion attendant upon a steep and perilous ascent; he likewise mentions a strong tendency to sleep, as another prominent symptom. His fellow-traveller Pictet appears to have suffered considerably, even at a height of 7,100 feet, from a general feeling of indisposition which he does not very clearly describe, together with a certain amount of nausea. The guides who accompanied them were obliged to halt for breath every few hundred paces, while De Saussure himself, who suffered less than the remainder of the party, was yet forced to rest repeatedly, on attaining the snowy cupola which forms the crest of the Buet. The elevation attained on this occasion was upwards of 10,000 English feet above the level of the sea.

As, at present, the object in view is to ascertain what are in truth the physiological phenomena observable at great altitudes, and by what physical sensations they are revealed, I trust the accusation of egotism may not be laid to my charge, if I compare the accounts given above, with my own personal experience, when ascending this mountain at the latter end of the autumn of 1845, a period so unfavourable to the attempt, that the Genevese journals declared the mountain to be no longer accessible. In company with three guides, we ascended the chain of which the Buet forms the culminating point, to a height of 7,000 feet, encamping for the night at about the level of perpetual congelation. Apart from a shortness and shallowness of the respiration, I perceived no unpleasant sensations, save those resulting from the cold. Early in the morning, upon resuming the ascent, my companion, a German lawyer, complained of much muscular debility in the lower limbs, as if they were about to give way from under him, but without the peculiar sense of fatigue which at an ordinary level usually accompanies this condition. I ere long was sensible of the same; and on reaching a height of 9,000 feet, we experienced

that uneasiness at the epigastrium which is so common at sea, together with such a shortness of breath as to render it necessary frequently to halt, and turn our faces away from the slope of snow we were ascending. I moreover noticed in my companion an unusually livid colour of the countenance, resembling the early stage of cyanosis, which subsided upon taking a few minutes' repose. On reaching the summit, none of our party, while abstaining from movement, found much to complain of; except that, in my own case; I felt a sensation which can be most appropriately compared to that perceived in a swing, when having attained its utmost stretch it prepares to return on itself, or to what is felt at the bow of a steam-vessel when elevated on a lofty wave which immediately recedes from under it.

Having read the account of De Saussure's ascent, previous to my own, I casually alluded to the sensations of which he speaks, in presence of the mountaineers who accompanied us, but I soon perceived that their bluntness of perception, together with their habit of living at various heights, precluded any attempt at obtaining information upon the subject. I resolved therefore to trust to my own feelings, and to those of my fellow-traveller, and these it will be seen tallied more or less with those described by De Saussure.

It has been however, upon the hoary monarch of the Alps, that the phenomena attendant upon a great elevation, have been most markedly felt and described; and while the above indefatigable explorer was one of the earliest of those who could boast of having scaled his summit, succeeding accounts have only served to ratify the truth and accuracy of his statements, a short outline of which may at present not be amiss. In describing the encampment of himself and party on the grand Plateau, at a height of 11,484 feet, he says: "At this time my guides, (men of strong constitutions, to whom seven or eight hours of previous exertion had been as nothing), could barely remove a few shovels full of snow, before they found it impossible to continue their task. One of them who had returned from a short distance, in order to collect some water which he had noticed in a crevice, was taken suddenly ill and passed the night in considerable suffering; I myself, though accustomed to the mountain air, and enjoying better health than when in the plain, felt exhausted to the utmost, simply from arranging and examining my meteorological instruments; we all of us, moreover, suffered from a constant but indescribable uneasiness, anxiety and thirst, while some of the guides were attacked during the night with nausea and vomiting.

"At the Petits Mulets, a height of 13,500 feet, the above symptoms became aggravated; and from thence to the summit, we found it impossible to take more than twelve or fifteen paces, without halting, while the greatest amount of nausea was felt about eight or ten seconds after doing so. The only relief I could obtain, was by turning my face to the north wind, which was blowing strongly, and swallowing large draughts of air. When arranging my instruments on the summit, and observing their indications, I found it necessary to rest frequently in order to gain breath. If I remained perfectly tranquil, I felt a tendency to sickness and indisposition; but if I attempted to direct attention to any particular object or to stoop for any purpose, so as to compress the thorax, I was forced to rest and gasp for some minutes. Similar sensations were experienced by my guides; they had no appetite, and cared nothing for wine or brandy, having discovered that such fluids served but to increase their uneasiness; cold water alone appeared palatable and productive of relief."

During the ascent of this mountain by Auldjo, an account of which was published in the year 1828, it appears that the first effects of a rarefied atmosphere were perceived at an elevation little short of 12,000 feet. The chief symptoms experienced by the narrator were considerable constriction of the chest, with difficulty of breathing, a frequent pulse, with a sensation of fulness in the head, and thirst. As the party continued to ascend, the individuals composing it almost all suffered from exhaustion and difficulty of

breathing, with violent headache and palpitation of the heart. At a height of 13,506 feet, Auldjo himself was attacked by a sudden and irresistible inclination to sleep, and felt himself completely overcome, cast down and disconcerted; while, on approaching the summit, which was only attained with the utmost difficulty by himself and guides, he was incapable of taking more than fifteen steps at a time. On reaching the highest point, he immediately fell asleep, and upon waking, the headache and pains of the limbs were found to have ceased, but he still suffered from thirst, difficulty of breathing, and rapidity of the circulation, while the sight and odour of food sufficed at once to produce nausea.

On the 19th of June, 1819, Dr. Reussœler and Mr. Howard attained the summit of the Mont Blanc. One of the guides was unable to proceed beyond the Grand Plateau; from this to the summit, the strongest of the party were unable to take more than fifteen steps in advance without halting. Howard himself was so severely indisposed, as to render it doubtful whether he would ever reach the summit.

In the month of August, 1825, Captain Sherwell, and Dr. Clark, likewise ascended the Mont Blanc. The former, on leaving the Grands Mulets, suffered much from thirst, cardialgia, and nausea; at a height of 9,600 feet, he was almost overcome by somnolence, and barely able to advance above a dozen steps without stopping. At the summit, the travellers felt much indisposed; Dr. Clark in particular was much oppressed in breathing, even while at rest, and experienced a sensation within the chest analogous to that which precedes an attack of hæmoptysis, to which when young he had been liable.

The following observations were made at different heights upon the Mont Blanc, by Dr. Martin Barry; they refer exclusively, as will be seen, to the physiological phenomena in question.

At a height of 11,001 feet he noticed a dry rugose condition of the integuments, lividity of certain parts of the body, tension of the surface, intense thirst, and gradual failure of the appetite.

At 13,640 feet, the symptoms were the same, with total loss of appetite, but without much fatigue.

At 13,713 feet, fatigue was perceived, with difficulty of breathing, relieved by halting and taking deep inspirations.

At 14,372 feet, there was tendency to syncope, increased dyspnoea, great prostration and indifference.

It is somewhat singular, that on one occasion during the ascent of this mountain, a dog, belonging to one of the guides, likewise suffered severely; he stopped continually, then fell down and slept immediately. At a height of 12,000 feet he vomited frequently, but nevertheless attained the summit, in company with his master.

M. Zumstein, in attempting to reach the highest peak of the Monte Rosa, appears to have suffered from the rarefaction of the atmosphere sooner than usual. At a height of 4,128 feet, he experienced so great a degree of anxiety and oppression, as to be unable to sleep during the night; after attaining an elevation of 10,800 feet, he and his companions were forced to halt repeatedly, and one of them fainted for some minutes. In ascending the pyramidal cone which constitutes one of the summits of the Monte Rosa, a chamois hunter of the party lost all consciousness.

Additional quotations might here be adduced, tending to confirm the statements of those observers, to whom allusion has already been made; I prefer, however, passing over these for the sake of brevity, and referring to the very accurate and detailed account which a French physician, Dr. Le Pileur, has given, relative to the phenomena of the mountain sickness, as noticed by himself, his companions, and guides, during successive attempts to reach the summit of the Mont Blanc. Speaking of his own sensations on attaining an elevation of 12,000 feet, he says: "I now experienced, after a few minutes exertion, a certain amount of fatigue, with dull contusive pains in the lower extremities. On counting my steps, I found that I could still take about a hundred without halting, the last twenty being performed

with much difficulty; after resting, the pain in the limbs ceased, and on resuming the ascent, the first few paces were comparatively easy. At a height of 13,350 feet, I perceived a slight degree of perspiration, lasting for a few minutes only. Prior to reaching the last rocks, situated near the summit, I became conscious of a most singular but indescribable uneasiness while in motion. There was no headache, no palpitation of the heart, nor any discomfort about the precordial region, but a general sense of great exhaustion and *malaise*, and I seemed in fact to have barely sufficient strength to execute the necessary movements of locomotion for a given period, after which I felt that any attempt to proceed would be fruitless. I could moreover advance but in one posture, namely, with the head inclined forwards, and the chin nearly touching the sternum. Each individual member of the party appeared to adopt this attitude, and I remarked that the act of halting and taking breath was similarly performed. A tendency to somnolence was also noticed; and what tended materially to increase the general sense of discomfort, was the dry, parched condition of the mouth. At a height of 13,580 feet, we were assailed by a violent north-west wind, which added to our suffering, more especially in my own case, inasmuch as a feeling of impending suffocation, with giddiness and nausea, was the result. This lasted for upwards of a quarter of an hour, during which it was necessary to exert all the moral courage I possessed, to continue the requisite exertion; I advanced indeed mechanically, without reflection; none spoke, and but one thought appeared to pervade the minds of the whole party, that of still accomplishing a few more paces in an upward direction."

The narrator proceeds to describe the sensations experienced by himself, his companions, and their guides after attaining the summit. These, as might be supposed from the absence of exertion, were less marked than during the ascent, and consisted for the most part in a tendency to somnolence, loss of appetite, thirst, slight nausea, and in one instance vomiting; he notices also the whiteness of the tongue, as occurring in every one of the party, together with a considerable acceleration of the pulse.

Upon a previous occasion, M. Le Pileur had been baffled in his endeavours to reach the summit of the mountain. At a height of 9,300 feet, one of the principal guides was suddenly seized with the "mountain sickness" and obliged to descend immediately. His countenance was bloodless, but covered with moisture, and he could but just take a few steps in advance; he recovered however upon descending about 600 feet.

At the Grand Plateau, another of the guides, Ambroise Coutet, was seized with nausea and a tendency to immediate syncope upon assuming the upright position.

A third guide, Simon, was similarly affected while M. Le Pileur was in the act of feeling his pulse, and had but just time to extend himself upon the snow, to avoid complete syncope.

In the year 1845, after residing three years in a perfectly level country, and with consequently no opportunity of becoming inured to mountain exercise, I spent some months in Switzerland; and on visiting the valley of Chamouni, proceeded at once with the assistance of two guides to attain the highest point on the Mont Blanc, capable of being reached without entailing the necessity of spending a night on the mountain. Beyond the ordinary fatigue and excitement, unavoidable upon such occasions, I felt nothing unusual until we had arrived at a height of 9,000 feet; here a sense of fullness in the head, and throbbing of the carotids, with palpitation of the heart, became evident. I had but little relish for food, and felt considerable thirst. At a height of 10,000 feet, I experienced a constriction of the chest, together with increased rapidity of the respiration, and this independent of the influence of severe exertion, inasmuch as the necessity for extreme caution, among the frightful labyrinth of crevices in parts of the glacier of Bossons, rendered the actual amount of exertion very trifling. For some time I had perceived the

taste of blood in the mouth, and this I found to be owing to a slight oozing from the gums. These peculiarities were, it is true, elicited at a comparatively early period of the ascent, which I attribute to the fact previously mentioned.

In the year 1846, when living among the Bernese Alps, I had still further opportunities of ascertaining the effect of great altitudes upon the body. In conversing at the hospice of the Grimsel, with some of the chamois hunters and attendants, who spend a large portion of the year at a height of 6,000 feet and upwards, I learned that habit had a great effect in doing away with those unpleasant effects which a rarefied atmosphere would produce upon an inhabitant of the plain. This I found to be actually the case during the ascent of one of the loftiest of the Bernese Alps, the Wetterhorn, or Peak of Tempests*. In scaling this hitherto untrodden summit, I was accompanied by three men, one an inhabitant of the plains, (although accustomed to ascend the lower and more accessible mountains in the neighbourhood), the two others habitually living at an elevation of between 6,000 and 7,000 feet, and inured to daily exertion of a severe nature. In these two men I could at no time detect aught that was unusual, save a shortness of breath, and a necessity for frequent halting during the ascent of the terminal ice-bound peak. The inhabitant of the plains however, evinced symptoms of distress at a very early period, and complained of nausea, thirst, oppression of the chest, and throbbing in the head. In my own case, the departure from the ordinary condition of health was but trifling, owing to having become somewhat accustomed to the atmosphere of lofty regions, and familiar with the species of exertion required to reach them. Occasionally, at some of the steepest and most dangerous parts, a feeling as if all power had been suddenly abstracted from the lower limbs, together with that sensation before described as experienced at sea or in a swing, necessitated a halt, and this sufficed to banish all unpleasant feelings. I may also add, that the whole party experienced a complete distaste for food, almost indeed amounting to loathing, and a wish rather for fluids. These we found to be very palatable and refreshing, when taken in small quantities. On arriving at the summit, I again felt the same peculiar sensation, previously noticed when on the Buét, together with increased rapidity of the respiration. The chamois hunters appeared but little inconvenienced; I remarked, however, that their distaste for food was as great as my own, while the guide who had accompanied me from Interlachen evidently suffered considerably from the effects of the elevated position upon which we stood; he appeared overcome by sleep, complained of throbbing in the head, nausea, difficulty of breathing and great thirst, and was utterly incapable of appreciating the stupendous panorama spread out before our eyes.

During the descent, comparatively few complaints were made by any one of the party, although the effects of the exposure to the reflection of an unclouded sun from the pure unsullied snow were very severe, and lasted for several days, producing vesication of the face, and in the chamois hunters an attack of ophthalmia; they having omitted to wear blue glasses during the ascent.

From these observations I conceive that, as a tolerably satisfactory answer to the first question proposed, it may be stated that at great elevations there actually do occur certain modifications in the natural functions of the body, in no way to be accounted for, but by admitting the existence of influences to which at an ordinary level it is not exposed.

[To be continued.]

* A detailed account of this ascent was published in the *Athenæum* of Nov. 1st, 1846.

CASE OF FIBROUS TUMOUR OF THE UTERUS, IN CONJUNCTION WITH PREGNANCY;

LACERATION OF THE PERITONEUM, AND HÆMORRHAGE INTO THE ABDOMEN.

By R. R. ROBINSON, F.R.C.S. Eng., late President of the South London Medical Society, and formerly Surgeon to the London Dispensary.

(Read before the Royal Medical and Chirurgical Society, Jan. 14th, 1851.)

CASE. In October, 1840, I was requested to attend a tradesman's wife, æt. 40, in her third confinement. I learnt that she had recently moved into her present residence, and that she had greatly exerted herself in cleaning it; that all through her pregnancy she had been much oppressed with flatulency, and had had misgivings about the result, having felt differently from what she had done on previous occasions; that four days previously she had slipped down four stairs, from which she did not experience any inconvenience; and that on the same day she caught her foot against a chair, which caused pain in her left hip, which she had at times felt since. I first saw her at noon; the membranes had broken eight hours previously. The pains had been frequent and regular. The external parts were relaxed. The os uteri was so far back that it could scarcely be felt, and was open to the size of an eighteenpenny piece; the vertex was presenting. She was at this time very much troubled with flatulency, for which warm gruel, with a little ginger, was given with relief. The pains continued strong and regular; the os uteri gradually dilated; and the child was born at four o'clock in the afternoon. It was large, blue, and almost dead, but recovered. The placenta was thrown off naturally shortly afterwards; the uterus contracted firmly; there was no hæmorrhage. I left her to all appearance well, an hour after her confinement. Her pulse was seventy-two in a minute: the urine had passed freely; the bowels had been opened five times that morning, and five times the day before.

About five hours after her confinement, I was called to her in haste. She had been allowed to remain undisturbed for two hours, when she was taken with cold chills; and upon being put to bed, she was seized with sickness (the flatulency still continuing), and she was very faint. Upon visiting her, I found her quite pale; her countenance shrunk, and very anxious; her lips pallid; the skin cold and clammy; the tongue very pale. She was conscious, but so faint that she could scarcely whisper. The pulse was all but imperceptible at the wrist; there was a very slight draining from the uterus; the breathing was slow and natural; sickness was constant; the abdomen was much distended, particularly below the umbilicus, and evidently tympanitic. The uterus could not be felt by the hand applied to the hypogastric region, neither did kneading pressure make it more apparent, or produce uterine contraction. Fearing that there might be internal uterine hæmorrhage, and not being certain about the state of the uterus, I introduced my hand with great facility, and found it somewhat large, empty, and flaccid. Thinking that relaxation of this organ might have had something to do with the symptoms present, I kept my hand steadily where it was, and, by means of an assistant, had pressure made externally upon the uterus; brandy and laudanum being at the same time administered. Finding but little good from these means, I tried the effect of cold. Wet cloths were first applied, and then a plate immersed in cold water, to the lower part of the abdomen; neither of which produced much effect. Cold water was therefore poured from a height upon the abdomen. This produced a slight shock upon the system, more decided uterine contraction, and more pulse. The uterus, however, again relaxing, it was necessary again and again to resort to the cold affusion. After each application, there were decided uterine contractions, more pulse, and a less anxious state of countenance. After an hour's trial of this plan, the uterus had contracted sufficiently to allow of my withdrawing my hand. Two

drachms of laudanum and much brandy had been given ; and although the skin was icy cold, and the pulse, though steady, 120 in the minute, the patient seemed more calm, and disposed to sleep.

On the following morning, I found that for an hour or two there had been a decided rally, and she had dozed a little : but there was then no real improvement. The countenance was very much pinched ; the skin deadly cold and clammy ; sickness was constant ; there was much flatulency ; and the abdomen was tender—not much distended, but decidedly tympanitic. She cried out at times, apparently from spasm of the abdomen. The pulse was exceedingly feeble. Bottles of warm water were applied to the feet and armpits ; and two assafoetida injections had been given, which came away almost immediately, expelling very little motion, and some flatus.

In the afternoon, the collapse being if anything more complete, a turpentine injection was administered ; mustard plasters were applied to the abdomen ; and ammonia with aromatic confection were taken every half-hour for some hours ; brandy and beef-tea were also given. In the evening, the pulse was stronger ; the skin warmer, and less clammy ; the sickness still continued ; there had been no motion. No urine having passed, a catheter was introduced, and about an ounce withdrawn. An effervescing draught was ordered to be taken every four hours, and the turpentine injection to be repeated in the morning.

On the morning of the third day, the injection was repeated, but returned instantly ; the pulse declined, and the woman appeared sinking. To my surprise, however, in a few hours there was a decided rally. The countenance, although shrunk, was more animated ; the cheeks were flushed ; the surface was warmer ; she took notice of objects, which she had not done before, and was even cheerful. The abdomen was not more distended, but tender to the touch ; the spasmodic pains recurred at times ; vomiting was incessant upon taking anything ; she had had no motion. The tongue was very much furred and dry ; there was incessant thirst ; the pulse was stronger, rather sharp, regular, 110. The urine had passed freely two or three times. The turpentine injection and the effervescing mixture were continued ; a bran poultice was applied to the abdomen, and calomel and opium ordered to be taken every four hours, in the form of powder.

On the fourth day, it is stated that the powders had been regularly taken ; several turpentine injections had been given ; and salts and peppermint-water were taken every four hours alternately with the calomel and opium. The sickness was incessant ; she had had one slight motion ; the abdomen was distended, and decidedly more tender upon pressure, especially the hypogastric and left iliac regions, where there was much greater solidity than elsewhere, and than had ever been perceptible before. She was ordered to continue the calomel and opium, and the salts and peppermint.

On the fifth day, it is reported that there had been some variations, but no important change for the better. The medicines were continued at longer intervals on the sixth day, and the injection was repeated ; after which about a pint and a half of fluid, tinged with fecal matter, came away ; and during the night and following morning several motions and much flatus were passed. The abdomen diminished in size, and was much less tender ; the hardness in the left iliac region greatly subsided ; and the uterus could be felt in the hypogastric region, about the usual shape and size for the time after delivery. There was also much less sickness.

On the seventh day, the tongue was more moist, and the surface warmer—more, however, from hot bran constantly applied to the abdomen than from the development of animal heat. The pulse was still feeble, and varied from 110 to 120. She was inclined to take nourishment, and she had, therefore, beef-tea and porter, and took them with relish.

On the eighth day, there was evidently more weakness and more emaciation. There was slight increase of sick-

ness, and hiccup occurred. The teeth were covered with sordes, and there were frequent alvine discharges. Mercury with chalk, opium, aromatic confection, and ammonia were prescribed, and a starch injection, with laudanum, was administered, by which the bowels were quieted. Refreshing sleep was procured by the acetate of morphia, but the patient became more and more exhausted ; the sickness and hiccup recurred ; she gradually sank, and died in the morning.

Dissection, twenty-four hours after Death. The body was not so much emaciated generally as might have been inferred from the aspect of the face and chest. The abdomen was not much distended ; it had some hardness and preternatural solidity at its lower part ; the peritoneum lining the abdominal parietes was of a dark green colour ; the intestinal convolutions were of a dark brown colour, in many parts being smeared with blood. Fully three pints of dark venous blood, quite free from coagula, were removed from the abdominal cavity. The convolutions of the small intestines were united to each other and to the uterus, by recent and easily separable adhesions. Upon breaking through these, there was observed, attached to the fundus of the uterus, but having no

Fig. 1. represents the large fibrous tumour attached to the fundus of the uterus:—the dark parts of it are where blood was extravasated ; the part under the tumour shows the size, shape, and situation of the uterus in the peritoneum. The back view of the uterus only is given, in which the ovaries, round ligaments, etc., are incorporated, the having been coagulated and matted together by strong spirit, in the preparation was immersed with a view of preserving the exact shape of the tumour.

communication with its interior, a tumour of livid and in size and shape like a moderate sized placenta, the diameter of which was placed transversely. This tumour was covered with peritoneum, a prolongation of the membrane enveloping the uterus : this membrane, near the an-

reflection, was lacerated to the extent of nearly two inches, and from it the blood found in the abdomen appeared to have oozed. Upon making an incision along the upper part of the tumour, nearly down to its uterine attachment, it appeared to be composed of three lobes—a right, a middle, and a left, the middle lobe being separated from the others by a white ligamentous structure. The right and middle lobes were softened, and of a deep chocolate colour, and appeared to be principally composed of a congeries of vessels; the left was of a pale brown colour, and had a fibrous aspect. The uterus was not firmly contracted, but of the size usual in a person so recently confined; its mucous membrane was of a dark colour. The os uteri was elevated and granular. A drop of purulent looking fluid issued from one of the veins, upon cutting into it. There was a patch of lymph, about the size of a shilling, on the mucous membrane of the upper part of the vagina. The ovaries, Fallopian tubes, and, indeed, all the other abdominal and pelvic viscera were healthy. The head and chest were not examined.

The preparation was subsequently exhibited at the Pathological Society; and upon a further incision being made into the tumour by Dr. Quain, a cyst, about the size of a walnut, containing a clear colourless fluid, was found in the left lobe, and the base of the tumour was found of a deep red colour, from extravasation of blood.

Dr. Quain also made a microscopical examination of the tumour, and the following is the account he has been kind enough to give me:—

"I have examined the specimens of tumour which you gave me, and find them to consist—First: In some parts of a fibrous structure, altogether analogous to that of fibrous tumours, but apparently more vascular: at least I can observe much larger and more numerous blood-vessels. Secondly: In the immediate vicinity of the cyst which was divided, I find the structure less distinctly like fibrous tissue; it is mixed with a quantity of granular matter, and numerous blood-vessels can be seen.

"The inference which I am disposed to draw is, that the tumour had increased during pregnancy,—the vascularity suggests that idea; and that this increase was subsequently much exaggerated by hæmorrhage and the coagulation of fibrin which subsequently took place. The length of time during which the preparation has been kept in spirits, renders the examination difficult, and its results doubtful; however, I have compared them with those found in an ordinary fibrous tumour kept under nearly similar circumstances."

REMARKS. I have been induced to offer this case to the notice of the Society, under the belief that there is not one exactly similar to it on record. Tumours of the uterus are not of unfrequent occurrence: they sometimes grow to a very large size; one is recorded weighing *forty pounds*.* They are not very unfrequently met with in conjunction with pregnancy; in some cases interfering with parturition, from mechanical obstruction, in others occasioning severe uterine hæmorrhage, as in a case mentioned by Hildanus, in two cases occurring to Madame Boivin, and in others recorded by more recent writers; but not one, I believe, has been mentioned where hæmorrhage has taken place into the abdomen, from rupture of the peritoneal coat which attached the tumour to the uterus. It appears to me also to have other points of interest, to which I will next allude.

There are three circumstances worthy of note in respect of the tumour: its structure, its situation, and its growth.

Structure of the Tumour. This tumour comes under that denomination described by a modern author as "a tumour, whatever its size or induration, growing externally; and, by

projecting the peritoneal coat of the uterus, obtaining from it an external covering."[†] It was in parts decidedly of a fibrous nature; but in others it possessed somewhat the characters of an erectile tissue. It was of a chocolate colour, and was composed of a congeries of vessels, together with ligamentous bands, and was softening in the centre, as if a malignant character had been implanted upon that originally fibrous.[‡]

Situation. The situation of the tumour was that most usually met with; and that perhaps, generally speaking, where it was least likely to be dangerous: it was placed upon the fundus of the uterus, immediately underneath the peritoneal coat. It was not so likely, therefore, to lead to uterine hæmorrhage on the one hand, as it would in all probability have done if placed in or under the proper uterine tissue; or to mechanical obstruction on the other, as would most likely have happened had it been seated laterally. Had this woman not been pregnant, it is probable that the tumour would have remained for many years without producing much, if any, inconvenience.

Growth. I am of opinion that the tumour, at first of small size, grew with great rapidity, in consequence of the

Fig. 2, exhibits two small fibrous tumours in the fundus of the uterus—one entire, the other cut open, to show its structure. If the woman from whom this specimen was taken had been pregnant, I think it possible that these might have grown with great rapidity, and consequently might have attained the same size as the other tumour.

* Ashwell, on Diseases of Women, pt. II, p. 286.

"The usual distinction must be drawn between the tumours and the out-growths of the same structure. The uterus presents examples of both. The fibrous uterine polypi, more properly so called, are continuous outgrowths of and from the substance of the uterus; the mucous membrane and the muscular and fibrous tissues of the uterus, growing in a variety of proportions into its cavity and that of the vagina. The fibrous tumours, as distinguished from these, are discontinuous growths of similar tissue in or near, not of the substance of the uterus."—*Paget's Lectures*, Lect. v, pt. I.

† One great object that I had in bringing this case before the Society, was the hope that the malignant degeneration of fibrous tumours would have been discussed: although disappointed in that respect, I am glad to find the subject considered by Mr. Paget, in his valuable Lectures, delivered at the College of Surgeons subsequently to the reading of this paper, from which I quote the following observations, as bearing upon this point:—

"I can scarcely doubt that certain tumours, presenting in all apparent structure the same characters, may in different persons appear innocent or malignant; but respecting the grounds of these differences, I can, as yet, scarcely offer a suggestion."—*Lect. v*, pt. II.

"In corroboration of the above remarks, allusion is made to a case where Mr. Lawrence removed a large well-marked fibrous tumour, which had grown nine months after one of the same appearance had been removed from the same part. Before removal, this was judged by all who saw it to be malignant; but it presented a genuine fibrous structure, and could not, I think, be distinguished from an ordinary fibrous tumour."—*Lect. v*, pt. II.

Also "to another of Mr. Stanley's, where a tumour recurring after removal more than once, amputation was performed. The tumour was milk-white, soft, and brain-like, except where discoloured by effused blood; and in the exposed parts, was soft, pulpy, and grumous. One would certainly, judging by its general aspect, have called this a brain-like medullary cancer; and yet it had essentially the same microscopic characters as the tumours I first examined from the same patient, only the narrow, elongated caudate cells were very generally filled with minute shining molecules, as if from fatty degeneration connected with protrusion and partial sloughing of the mass."—*Ibid.*

"Whatever be the truth concerning the supposed transformation of an innocent into a malignant morbid structure, I think it cannot be doubted, that in the cases of some recurring growths, the successively later growths acquire more and more of the characters of thoroughly malignant disease."—*Ibid.*

* Lever, on Diseases of the Uterus, p. 111.

† The extent of growth appears unlimited, and among the fibrous tumours are the heaviest known. They have weighed fifty, sixty, and seventy pounds. Waller refers to one of seventy-four pounds; and to one described in an *American Journal* as having been estimated at one hundred pounds."—*Paget's Lectures*, Lect. v, pt. I.

large supply of blood to the uterus during pregnancy; and this view is, I think, confirmed by Dr. Quain's microscopic examination, and by the appearance of another preparation, which I also exhibited, and also by the way in which it was covered, and, as it were, *entangled* by the convolutions of the intestines.

Source of the Hæmorrhage. Upon this point there can, I think, be but little doubt; for upon elevating the uterus, with the tumour attached, a laceration, about *two inches* in extent, in the peritoneum, going from the posterior part of the uterus to the tumour, was at once apparent; and as there was no other laceration in that membrane, it seems all but certain that the bleeding had proceeded from it. This constitutes the great peculiarity in the case, as it is the only one with which I am acquainted where a fibrous tumour of the uterus has terminated fatally in that way.

Cause and Time of the Hæmorrhage. At the cause and time of the bleeding, there is some difficulty in arriving. It seems most reasonable to conclude that the rent was produced when the uterus was contracting violently, during the birth of the child: the tumour being entangled among the convolutions, could not follow the uterine movements so quickly as was necessary, and thus the peritoneum was put upon the stretch, and, upon the recurrence of pain, gave way. But, on the other hand, had that been the case, collapse would in all probability have occurred at the moment of birth, whereas no sign of anything being wrong was then apparent. The placenta was thrown off by the natural powers about the ordinary time, without any inconvenience; and it was not until the woman was put to bed three hours after the child was born, that the mischief showed itself.

Cause of the Collapse. This point is also involved in obscurity. If it arose from the rupture of the peritoneum, the cause most likely to have produced it, and if that took place at the time I have suggested, it would most probably have shown itself earlier; if it arose from the hæmorrhage, the symptoms to have been expected were simply those of syncope; and although these were the symptoms first manifested—namely, chilliness, paleness, sickness, and faintness, yet when I arrived they were decidedly those of collapse,—a shrunk and very *anxious countenance*; a clammy skin, so peculiar to this condition; a voice scarcely beyond a whisper; and a pulse all but imperceptible at the wrist. The only conclusion, therefore, at which I can arrive is, that her condition was partly owing to the extravasation of blood, and partly, also, to the rupture of the peritoneum. This possesses additional interest when contrasted with another case of extensive abdominal hæmorrhage, conjoined with rupture of the peritoneum, that came under my care, and which is already published.* The symptoms were in many respects the same in both; and in both there was nearly the same amount of blood extravasated; yet in one case death was produced in about *twelve hours*, and in the other the patient survived until the *tenth day*. In one, the patient was at once destroyed by the shock to his system; in the other, death appears to have ensued from atonic peritonitis. May not the difference in the treatment pursued in some measure explain this? The case so rapidly fatal was attended by spasm and pain of the abdomen, which naturally called for the application of *warmth*; whereas the other, occurring so soon after labour, and having some symptoms in common with internal uterine hæmorrhage, as naturally suggested the application of *cold*, by which it is probable that the hæmorrhage was in some degree arrested.

Another question arises here. Was the blood found in the abdomen all extravasated soon after the laceration? or did it continue to ooze up to the close of life? Upon the first supposition, the blood would most probably have been found coagulated, (its non-coagulation is extraordinary under any circumstances,) and might have been otherwise changed; upon the latter, it seems scarcely reasonable to suppose that the patient would have rallied at all.

Cause of the Peritonitis. The inflammation of the peritoneum, which partook of the enfeebled powers of the constitution, appears, like the collapse, to have had a two-fold origin, and to have been attributable partly to the rupture of the peritoneum, and partly to the presence of extravasated blood.

Induction of Premature Labour. Could this woman's condition have been known, there seems great likelihood that her life might have been preserved by the induction of premature labour; as, at an earlier period, in all probability the tumour would not have been so large as it was at the full period of gestation; it might not have been so entangled in the intestinal convolutions; and the pains for expelling the child might not have been so strong. Laceration, therefore, would have been less likely to have followed. But as, until the fatal event, there never was any sign which could lead to the supposition that such a tumour existed, the induction of premature labour could never have been contemplated in this case. As, however, it brings to light a fresh danger connected with these cases—namely, rupture of the peritoneum, from long-continued uterine action, it affords an *additional* reason for advocating premature delivery where the existence of a uterine tumour in conjunction with pregnancy is clearly ascertained.*

I cannot help alluding, in conclusion, to the serous cyst subsequently discovered in this tumour; and I do so chiefly to introduce the following observations from Mr. Paget's Lectures.

"We find examples of fibrous tumours thickly beset with small, well-defined, and lined cysts. This appears to be the nature of the hydatid testis described by Sir A. Cooper. A similar condition may be found, but is rare, in fibrous tumour of the uterus. In another set of cases, we find one large cyst existing alone, or far predominating over all the others in a fibrous tumour. This is most frequent in the tumours in the nerves and in the uterus. In the latter organ it has peculiar interest, because the cyst, if it attain a great size, may be mistaken, and treated for an ovarian cyst. Several such cases have happened. In the College Museum is a preparation, the history of which, sent by Sir E. Home, is that it is a portion of a uterus in which a very large encysted tumour had formed. The patient had been tapped twice, and the cyst emptied. The case was supposed to be ovarian dropsy during life. In another case, Mr. Caesar Hawkins, suspecting ovarian disease, drew fifteen pints of fluid from a great cyst in a fibrous tumour of the uterus. The patient died a long time afterwards. The specimen, which is in St. George's Hospital, shows an enormous fibrous tumour in the side wall of the uterus, having one vast cavity, and in its solid part many small cysts." (*Lect. v, part 1.*)

NOTES ON THE TREATMENT OF ERYTHEMA NODOSUM, URTICARIA, AND ERYSIPELAS.

By W. S. OKE, M.D., Physician to the Royal South Hants Infirmary.

1. **ERYTHEMA NODOSUM.** This is a disease of not unfrequent occurrence, and is met with in females from the age of puberty to about 25 years. It more commonly affects cottagers and servants, and is rare amongst the better classes of society.

The eruption is characterised by tumefactions of the skin, of an irregularly round or oval shape, and about the size of the long section of a damson. The spots are at first red, but soon become more or less livid, and assume the ap-

* From what took place at the discussion of my paper, I fear the above observation was misunderstood; some explanation may therefore be necessary. It was very far from my intention to advocate the induction of premature labour in all cases of fibrous tumour, or indeed in fibrous tumour as a rule at all; but only to suggest, that as certain reasons have been assigned for that operation, such as want of space for a full-sized fetus to pass, the blocking up of either the inlet or outlet of the pelvis by tumours, &c., so, should a fibrous tumour be discovered before parturition, and be observed to be growing rapidly, then the fear of the rupture of the peritoneum from strong uterine action would be an *additional* reason for resorting to this proceeding.

pearance of a bruise. They usually appear on the lateral and anterior surface of the legs, and are painful and tender, causing the space between the knee and ankle to swell. They never vesicate, nor do they terminate in suppuration.

This exanthem does not appear to run its course in any definite number of days, and generally lasts for some weeks, unless its progress be shortened by medical treatment.

This kind of erythema is accompanied by a considerable degree of febrile disturbance. The pulse is not much under 100 in the minute; the tongue is white; the urine is high coloured; and there is thirst, great lassitude, restlessness, and impatience.

The languid aspect of the patient would sometimes appear to indicate the use of tonics, even in the early stage of the disease; but these invariably aggravate the symptoms. The mode of treatment which I have always found successful, is calomel combined with antimony at bed-time, and saline aperients during the day, as in prescriptions 1 and 2.

This treatment, with a cooling diet and confinement to bed for a short time, will speedily relieve the patient and terminate the symptoms.

II. URTICARIA. The name given to this cutaneous eruption is remarkably happy, as it is in strict accordance with the appearance of the nettle-sting. It is evolved in circular whitish wheals, with a slightly red base, and is accompanied with tingling and prurience. In some parts it is distinct, and in others coalescent. Common urticaria is, in many instances, the almost immediate result of having eaten some crude, indigestible food, such as mushrooms or shell-fish, especially muscles, oysters, lobsters, prawns, and the like; and the cutaneous eruption will probably be preceded or accompanied by pain or inflation of the stomach. The rash in such a case is generally removed with its cause. The pill (1) and the draught (2), repeated twice or thrice at proper intervals, will usually suffice.

There are examples of urticaria, which are far less evanescent, always within call, and which tease the patient from time to time, for months or years. Such cases depend more upon a chronic excitability of the gastric or intestinal mucous membrane, acted upon by indigestible food and acrid secretions. This kind is curable by such means as will gradually restore the digestive functions to a healthy state; and as this is effected, the urticarial rash will diminish and ultimately disappear. The remedies to be used will of course be indicated by existing circumstances; the formulæ 3 and 4 will often succeed; but the entire removal of the eruption will chiefly depend upon the strict observance of a light diet, the avoiding of all fermented drinks, sufficient clothing, and regular exercise.

A course of tepid or vapour baths will often conduce to the cure of protracted urticaria.

I have sometimes seen urticaria accompany severe erysipelas. The wheals assumed a deep purple hue. In such an association, it will, of course, fall under the treatment of the latter disease.

There is a singular species of urticaria occasionally met with, called *tuberosa*, which appears in much larger elevations; and when they occur in any part of the face, they occasion great disfigurement, especially if the lips or one of the *alæ nasi* should be bunched out. The tongue is sometimes the seat of one of these huge wheals, to the great alarm of the patient.

CASE. A married lady, æt. 30, whilst on a visit in the neighbourhood of Southampton, was suddenly attacked in the night with a sense of suffocation and difficulty of deglutition. She was greatly alarmed, and sent in haste for me. On examining the internal fauces, a large wheal of the urticaria *tuberosa*, situated upon the upper and back part of the tongue, was found to be the cause of her distress. An inquiry was then made, whether she had eaten anything which might have disagreed with the gastric function; when she acknowledged that she had made a hearty supper on oysters. This at once satisfactorily explained the nature of the case, and set the mind of the patient at rest. The symptoms were soon removed by a smart purge, and saline effervescing medicine.

The *urticaria febrilis* is very rarely seen. I cannot say that I have met with more than one distinct example of it. It came out principally on the fore-arms, and the wheals were surrounded by a florid areola. They were accompanied with smart pyrexia, and ran a course of about eight days, without being in any wise controlled by the influence of medicine.

III. ERYSIPELAS (incipient stage of). Erysipelas is an inflammatory outbreak of a distinct character; and it may be either idiopathic or traumatic—the result of morbid causes, or of external injury. The former most frequently attacks the face and legs; the latter may attack any part of the surface which might have been injured by accident or operation.

Erysipelatous inflammation is somewhat sudden in its attack, diffuse, and bounded by a well defined and abrupt margin. If momentary pressure be made upon it, the blood recedes from the capillary vessels; and, as soon as the pressure is removed, it is seen to flow into them again.

Erysipelas generally commences with simply an inflamed and congested state of the surface; but this often rapidly occasions serous infiltrations beneath the cuticle, raising it into bullæ of various sizes; or suppurative action in the areolar tissue, forming abscesses; or even gangrene of the part involved: and these are the results of one and the same disease.

The inflammation is also of a serpiginous character, leaving one part and extending to another. Thus, if it commence in the integuments of the nose, it will often leave that feature, pass over the palpebræ and cheek to the temple and ear, and thence to the scalp. In some severe cases, it will not stop there, but extend down the neck and over the greater part of the integuments of the thorax.

Erysipelas is commonly ushered in by severe rigor; but the amount of disease about to follow may not be in proportion to the degree of this symptom. I have known a shivering, threatening a serious attack, to be followed by a mere erysipelatous blush of the integuments of the leg, without the smallest vesication, or any suppuration.

Erysipelas does not always observe a definite course,

like some other febrile eruptions. It may terminate in eight or nine days, or it may last a month, an instance of which I have lately met with in a lady, *æt.* 50. It began in the face, on the 2nd of November; and after traversing the head, neck, and trunk, terminated fatally on the 12th of December. It was remarkable that the case, in its last stage, assumed the character of urticaria, which came out in large wheals, of a deep red colour.

This disease seems to be often derived from a morbid poison; and it may be sporadic or epidemic. Whether it be contagious, is a question of great importance. That it spreads in the wards of hospitals, and in crowded families, from the want of cleanliness or ventilation, or from deficient drainage, is a well-known fact; but under such circumstances, it is difficult to decide whether it be communicated from person to person, or generated from an impure atmosphere. The safest decision will be, that it may arise from both.

Erysipelas is sometimes very fatal in public institutions, especially in hospitals for the sick; indeed, it has sometimes proved so frequently fatal in these places, that the surgeons have been unwilling to perform even the slightest operations, during the existence of the disease, lest the patient should be subsequently destroyed by an erysipelatous attack—an event by no means uncommon.

Erysipelatous action has been treated by a variety of remedies—each surgeon or physician adopting his own peculiar mode of treatment; but, until lately, it does not appear that any method of cure has been entitled to much confidence. It is to Mr. Higginbottom that the public are indebted for the discovery of the external application of a strong solution of the nitrate of silver, as a remedy for this disease (*London Medical and Physical Journal*, vol. xlviii, p. 223); and it is certain that this medicine possesses a therapeutic power in arresting its progress. The Royal South Hants Infirmary, in common with other hospitals, has been occasionally invaded by erysipelas, with an average result; but since the nitrate of silver has been employed, the unfavourable terminations have been comparatively very few; and I am persuaded that, were this excellent remedy more frequently adopted, erysipelatous inflammation might be generally controlled.

A relative of mine, Mr. Robert O. Clark, of Farnham, who was Resident Surgeon in this establishment for two years, informs me that he never hesitated to apply the lotion (1) on the first appearance of the disease, and that it hardly ever failed in arresting its progress.

- 1.—*Rx.* Argenti nitratis \mathfrak{z} j.
Acidi nitrici *gtt.* vi.
Aque puræ \mathfrak{z} j. Misce.

This formula does not, I believe, contain so large a proportion of the nitrate of silver as that recommended by Mr. Higginbottom; but it is sufficiently strong to answer its purpose.

If the erysipelas be of the asthenic kind, as it usually is in hospitals, the system is to be supported by the mixture (2), with a generous diet, and the bowels must be regulated by a gentle aperient (3).

- 2.—*Rx.* Acidi nitrici diluti \mathfrak{z} j.

Fiat haustus.

CASE I. Ellen Borsell, a domestic servant, *æt.* 19, having suffered severe headache for four months, was admitted into the Royal South Hants Infirmary under my care. The functions of the body were healthily performed, except that menstruation was deficient. Blisters were applied to the temples, which caused the face to swell, and brought out a crop of large pustules. Flour was applied to them, and they were subsiding, when an attack of erysipelas came on

with shivering: it began at the pustules, and spreading over the forehead and cheek. She was in great pain; the pulse rose to 130 in the minute, and the bowels were confined. The erysipelatous surface was painted over with the solution (1), and a purge was given. This was on the 31st of December, 1850. On the following day, the part so painted was deadened; but as the disease had spread to the other side of the face, the solution was applied there also; and she was ordered to take the mixture (2), strong beef-tea, and \mathfrak{z} ij of wine daily.

Jan. 2nd. The erysipelas was much faded; the pulse was 120; she had taken nourishment well, and was in less pain.

Jan. 3rd. She felt better; the erysipelas had spread but slightly; pulse 100. The parts were again painted over with the solution. The same diet and medicine were continued.

Jan. 6th. Since the last date, she had rapidly improved, and the erysipelas had left her.

CASE II. In the spring of 1850, one of the inmates of the County of Hants Female Penitentiary (where no instance of erysipelas had ever before occurred, although it had been established more than twenty years,) was attacked with erysipelatous inflammation of the right cheek, accompanied by headache, febrile disturbance, and a pulse of 120 in the minute. Fearing lest the disease might spread amongst the women of the house, I immediately brushed the inflammation over with the solution (1), giving her, at the same time, a gentle aperient and some saline medicine. On the following day, it was manifest that the solution had arrested the local progress of the disease, and moderated, also, the febrile symptoms, the swelling and redness having greatly subsided, and the pulse being reduced to 84. Wherever the inflammation showed any disposition to spread, the part was again brushed over with the solution, which never failed to stop its progress. In a few days she was convalescent; and no other case occurred in the house.

These cases are not added as anything new, but merely as facts in confirmation of the efficacy of this treatment.

Should the internal fauces become involved in the erysipelatous action, the solution should be applied to the throat also, as often as it may be deemed necessary.

In the incipient stage of vesicular erysipelas, I have seen the application of honey attended with the happiest effect, in at once arresting the spread of the disease, and subduing it altogether. My attention was first drawn to its therapeutic efficacy, by observing that an eruption of an erysipelatous character, spreading from the external angle of the left eye, rapidly disappeared after having been smeared with honey; and afterwards, having found it equally successful in similar conditions of the skin, I resolved to give it a fair trial for the local treatment of incipient erysipelas, on the first opportunity that presented itself, and this soon occurred.

In the month of October, 1851, the senior nurse of the Royal South Hants Infirmary, was attacked with vesicular erysipelas of the face; and, in a few days afterwards, four female patients in the ward adjoining her bed-room, were attacked in a similar manner. The symptoms certainly were of a mild character, though well marked. There was headache, whiteness of the tongue, febrile action, and, in some, there were small vesications upon the cheek. I immediately ordered the inflamed surface, in every case, to be well smeared with honey, morning and evening, and that no other remedy should be used. On the following day, I was surprised to find that in each patient the progress of the disease was effectually arrested, and that the inflammation had subsided in a remarkable manner. On continuing the honey as directed, the disease rapidly and completely subsided. I am fully aware that the external application of honey cannot be considered as a remedy for the cure of incipient erysipelas, even of a mild kind, upon so scanty a report of its efficacy; but I have deemed it my duty to state the fact, that others may make trial of it, and report its effect.

ERYSIPELAS PHLYCTENODES, Zoster, or "Shingles", is a species of erysipelas. It appears in groups or clusters of phlyctenæ, and commonly selects for its development the integuments of the thorax or abdomen. It is less frequently seen on the face and extremities. There is commonly some slight febricular disturbance of the system, and great soreness of the parts involved; and after the eruption has disappeared, it leaves a painful sensation beneath the skin for a considerable time.

There does not appear to be any settled treatment of this disease, either internal or external; and, therefore, it is generally left to take its course. I am not prepared to state from facts, that the solution of the nitrate of silver would at once obliterate this form of erysipelas; but, judging from its decided effect in the preceding form of the disease, there is every probability that it would be equally effectual in this.

Southampton, January, 1858.

CASE OF UTERINE HÆMORRHAGE, APPARENTLY SIMILAR TO THAT RECENTLY REPORTED BY MR. HARRINSON.

By WILLIAM EDWARD CROWFOOT, F.R.C.S.

THE perusal of Mr. Harrinson's case of uterine hæmorrhage induces me to publish the following case, which occurred in my practice a few years since, and which appears to be of a similar character. Two analogous instances are given in the *Practical Observations on Midwifery*, by Drs. McClintock and Hardy, p. 194.

CASE. In August, 1841, I was summoned, in the middle of the night, to a poor woman who was in labour, under the care of a midwife, at the distance of three miles from Beccles. She had been frequently pregnant, but in every instance, except the last, her children had been born dead, in consequence of hæmorrhage either previous to, or during her labours. On the last occasion, I attended her, and ruptured the membranes immediately upon my arrival, and the child was born alive. In consequence of her poverty, she engaged a midwife to attend her, who, when she had been three hours in labour, assured her that she was doing remarkably well. In spite of these assurances, the poor woman felt that all was not right; complained of extreme faintness; told her husband she was confident she should die, if not immediately delivered, and begged him to lose no time in coming for me. Her fears proved but too correct; for almost before he could leave the house, she expired. Upon my arrival, an hour after her death, I made an examination *per vaginam*, and found little or no external hæmorrhage, but the os uteri completely dilated, the vertex presenting, and the head firmly wedged in the bones of the pelvis. The midwife could in no way account for the disastrous result, and said that everything appeared to her to be going on naturally; that the patient had no loss, but only complained of a great feeling of faintness.

On the following day, I made a *post-mortem* examination of the body, which was that of a fine, well-formed female, of thirty-five years of age. Upon opening the abdomen, the viscera were found healthy, but pale and anæmic. The placenta, which had been attached to the posterior surface of the uterus, was separated throughout a large extent from its attachment; and coagulated blood, to the amount of six pounds, with a proportionate quantity of serum, was effused between it and the uterus. The head of the fœtus was so firmly wedged in the pelvis, that I had some difficulty in withdrawing it; and this circumstance accounts for the non-escape of the hæmorrhage externally. Had the membranes been ruptured at the commencement of labour, this poor woman's life might possibly have been saved.

Beccles, Suffolk. January 10th, 1863.

BIBLIOGRAPHICAL NOTICES.

THE CLIMATE OF ITALY, IN RELATION TO PULMONARY CONSUMPTION; WITH REMARKS ON THE INFLUENCE OF FOREIGN CLIMATES UPON INVALIDS. By T. H. BURGESS, M.D., etc. London: 1852.

AMONG the desiderata of the present day, as far as the treatment of pulmonary affections is concerned, it must be admitted that the choice of a suitable climate for patients is one of very great importance. While hospitals have been established for the treatment of phthisis and its cognate maladies, and while a more perfect knowledge of physical diagnosis is daily on the increase, it is surprising how little attention has been paid to the choice of a suitable sojourn for the consumptive invalid. How many, alas! have been sent to linger out their days on the inhospitable shores of a foreign land, without regard to its suitability, either economically or medicinally; a warm climate being in some cases only regarded, and a constant sea-breeze in others; no care, no thought, is bestowed on the capabilities each may present as a residence for the sick and dying; and while some weary from their very flatness, others partake so much of the mountainous in their character and external features, as to render walking exercise impossible. Too little importance has been attached to the natural air of the sick; and medical men have yet to be informed that Great Britain itself possesses spots to which pulmonary invalids may resort with benefit.

"The purpose," says Dr. Burgess, "of this volume is to show, that to send consumptive patients to Italy or to the South of France, for the benefit of their health, is a mistake; and that the climate of the United Kingdom, as yet very partially and imperfectly understood, will afford to the English consumptive patient as great if not greater chances of recovery than that of either of the former countries, provided a proper locality be selected. If," he observes, "we contemplate the climate theory through the appropriate medium of the natural history of creation, we shall find that the argument is also in our favour. We may seek in vain along the entire range of organized existence for an example of diseased animals being benefited by a change from a warm to a cold, or from a cold to a warm country. There appears nothing in the book of nature so violently inconsistent. The fishes, which inhabit the waters of the British Islands, will not thrive in the Arctic seas, nor those of the latter in the oceans of the tropics. The birds of the forests of America generally die in this country, unless reared like hothouse plants; and so with the wild animals which live and flourish in the jungles of Asia and the scorching deserts of Africa. Man, although endowed with the faculty of enduring such unnatural transitions in a remarkable degree, nevertheless becomes sensible of their injurious results. The child of the European, although born in India, must be sent home to the climate of his ancestors, or to one closely resembling it, in order to escape incurable disease or premature death. The accident of birth does not constitute the title to any given climate. The natural climate of man is that in which not only he himself was born, but likewise his blood relations for several generations. This is his natural climate, as well in health as in disease. * * * *Change of air in his own climate*, or removal to one nearly approaching to it, is the natural indication, and will accomplish whatever good climate can effect in consumption." (p. 21.)

"If there be on earth a spectacle of misery utterly deplorable," says Whiteside, "it is that of consumptive patients, in an advanced stage of that fatal disease, wandering through Italy in search of health. Unacquainted with the language, the people, and the habits of the country, they endure an accumulation of vexations, increase the suffering they had hoped to mitigate, and hasten the progress of a malady they fondly expected climate would retard or avert. There can scarcely be a question, that a residence at home, in a favourable situation, would be preferable to a cheerless residence in many parts of Florence, Rome, or Naples; and yet a patient may be sent abroad at such a period of the year as to render it impossible to procure a healthful abode with a sunny aspect and some of the comforts he would require. The churchyards of the towns in Italy frequented by English invalids, teach a melancholy lesson on this subject." (Whiteside's "*Italy*.")

Dr. Burgess justly observes, that a revolution must take

place in the system of every consumptive invalid who goes to Italy, before he can become acclimated : and how many, he asks, must sink under the probationary process, from fatigue and exhaustion ? (p. 23.)

Every person interested in this important subject should peruse Dr. Burgess's work with attention. It is a candid and impartial inquiry into the merits of the various foreign climates hitherto recommended, showing clearly the impolicy, not to say unkindness, of sending dying patients abroad in search of an *ignis fatuus*. How often is the visit to a foreign climate postponed, from the instinctive love of home and all its endearments and fond associations, until change of air, the only real reason for undertaking it, has ceased to afford the shadow of a prospect of benefit ? Surely it is not unworthy the talents and industry of our provincial physicians, to endeavour each in his locality and sphere of observation, to inquire how far particular places in Great Britain fulfil the requirements of the consumptive invalid. It is a work of too great magnitude for any one person to attempt, in the present state of meteorological science ; all that we can hope to do, is, to collect observations and make deductions for the benefit of a future writer on the climate of England.

We will now accompany Dr. Burgess in his remarks upon the climate and peculiarities of the various localities usually recommended to consumptive patients. These we shall abridge, referring to the work itself for more full details.

MALTA has long been a favourite resort for phthisical patients ; yet it stands prominently forward in the army reports as yielding a high mortality from consumption. The vicissitudes of temperature are exceedingly trying. Mr. Lawson observes, that the difference between the temperatures of the warmest and coldest months is very considerable, being at Malta equal to and at Corfu even greater than at London. I have seen, says Dr. Burgess, the thermometer at Malta stand at 32° during the whole day, with a fresh breeze from the north ; and even in the latter end of March, after a fall of hail, distinct traces of it were found in Valetta five hours after it fell. The climate presents much the same characters at Gibraltar and the Ionian Islands. In sixteen years, at Gibraltar, easterly winds prevail annually 184 days ; westerly, 177. Snow and ice are rare, but during the winter the cold is keenly felt by those who have been long resident there. Mr. Spencer Wells, who has resided for several years in the hospital at Malta, corroborates the preceding remarks on the mortality from consumption. During the year 1842, 813 patients were under treatment in the Royal Naval Hospital at Malta. Of these 813 patients, 51 died within the year, of whom 17, more than 30 per cent. died of phthisis alone. The sirocco makes no distinction ; its effects are felt in the sick chamber of the rich as well as in the barrack-room of the soldier. While it is necessary to breathe to carry on life, the baneful effects of this Syrian blast must be more or less felt by all who live within its influence.

MADEIRA, says Dr. Burgess, is now perhaps the most frequented of all the foreign depôts for consumptive invalids ; yet Mr. White, a recent writer upon the subject, reluctantly admits, that, although the climate is so very equable, it is not altogether free from those sudden changes of climate which constitute every where the exciting causes of pulmonary disease. Mr. White tells us, that the currents and eddies caused by the vicinity of the mountains render either a vane or aerometer of very little use ; and that, from the position of the island and nature of its surface, the sky cannot be so clear or the atmosphere so calm as in Italy. Dr. Mason, indeed, complained bitterly of the cloudy sky, the high winds, and variability of the climate of Madeira. This worthy man and enlightened philosopher ultimately fell a victim to pulmonary consumption, and occupied himself, during a residence of nearly two years, with meteorological investigations which were afterwards given to the world in a work entitled "A Treatise on the Climate and Meteorology of Madeira," by the late J. A. Mason, M.D. Edited by James Sheridan Knowles. London : 1850."

"With respect to the hygrometric condition of Madeira," says Dr. Mason, "we must enter into some detail, particularly as no one has confirmed Dr. Heineken's observations, which appear to have been greatly overlooked by the medical profession, who persist in regarding the climate of Madeira as *essentially dry* ; whereas, if any confidence can be placed in the data obtained by Dr. Heineken and myself, it must be admitted to be saturated with humidity during the greater part of the year ; in which respect its advantages are little superior to the climate of London, while, as regards the action of humidity on the organization, it is infinitely inferior."

Dr. Mason supports this statement by a series of tables, from which it appears that, at the temperature of 50°, which is near the mean temperature of London, the air, if saturated, is capable of holding 100 parts of moisture in solution ; while, at the temperature of 68°, which is rather above the mean temperature of Funchal in Madeira, it will contain 200 parts, or nearly double what it is able to hold in London.

Madeira has its *sirocco* as well as Italy. The *sirocco*, however, is essentially different in its character ; it is hot, moist, and relaxing, whereas the *leste* of Madeira is essentially hot, dry, and stimulating, so that it soon exhausts those in health by its exciting qualities. It will be observed, that Mr. White, in the tables appended to his work, leaves out altogether the *leste* from his calculations of the mean monthly range of the thermometer.

It appears from Dr. Mason's tables, that the dryness observed during the *leste* is 22° 5', while the mean annual dryness is at the most 3°. In fact, his observations, taken in London, on his return home, go to prove that London is drier than Madeira during the months of June and July, when his observations were made. We must refer to Dr. Mason's work for other proofs of the dampness and variability of the climate, and content ourselves with quoting a few of his observations.

"The very frequent and remarkable variations in a given series of years incontestably prove that Madeira is no more to be relied on than any other place for certainty of fine weather ; and that it has equally its annual vicissitudes of temperature." "It is a rare occurrence to see it clear and free from detached clouds even for two or three hours together." "Within twenty-four hours after the *leste* has ceased, there is a copious fall of rain. Thus, we find, that the whole atmosphere, from being intensely dry, becomes surcharged with humidity."

Drs. Heineken and Gourlay both agree that no disease is more common among the natives of Madeira than pulmonary consumption, and Dr. Mason confirms the fact.

"From my own experience," he says, "I should be inclined to corroborate Dr. Gourlay's opinion, that consumption and scrofula are frequent in Madeira. From what has been stated by writers respecting the salubrity of Madeira, a person might be led to imagine that disease was scarcely known there ; but I am afraid, that, were the subject thoroughly investigated as it ought to be, few places would be found where the system is more liable to general disorder ; while, at the same time, I suspect that the average duration of life would turn out to be inferior to that of our own country." (Mason, *op. cit.*, p. 108.)

"The strangers' burial ground," says Mr. White, "has a melancholy appearance, and one lingers not unwillingly among its rich and fragrant flowers, while reading with sadness the simple tale of many who, in the bloom and joy of youth, having sought these shores for a relief to their sufferings through the influence of its balmy climate, and far removed from the endearing ties of friends and home, have only found that relief in the grave." (White, "*Madeira, its Climate and Scenery*," p. 29.)

If from Mr. White's tables we select the month of April, 1850, we find that the mean maximum of the thermometer in the day time was 73°, while the mean minimum at night was 60°. During the same month in Bath, the mean maximum was 56°, and the mean minimum 42° ; the mean for the whole ten years being 55.7 and 41.3. And the inquiry naturally arises, in what respect, except in that of its heat, does a climate excel whose mean monthly range of thirteen degrees is contrasted with a native climate of a mean range of fourteen degrees ? On the contrary, it appears to us that it possesses a disadvantage ; for every one who has been in a warm climate testifies to the extreme suffering produced

at night even by the loss of a few degrees of heat; while in this country a mean monthly variation in April of between 56° and 42° could produce no serious amount of mischief to one of its inhabitants. A loss of temperature in Madeira from 70° to 58° would, in a susceptible individual, produce greater distress and irritation than a fall in this country from 50° to 32°, even though it touched the freezing point; because in the warmer climate the skin is the more active agent, and in the colder, the kidneys. In the former, the functions of the cutaneous surface would be checked; whereas, in the latter, the ordinary temperature would not have risen sufficiently to call it into action.

It is thus that we ought to regard the temperature of a climate warmer than our own, in reference to its influence upon the health of the English invalid. Its suitability is not to be measured by the rise in its thermometer, but rather by the difference between the maximum and minimum degrees of heat in a given period of time. Where is the advantage of seeking abroad for a climate, whose variation of temperature during a month like April is only one degree less than that of a valley within three hours' distance of the metropolis of Great Britain?

"A low degree of temperature," says Dr. Burgess, "with a limited range, will give more permanent ease to persons having diseased lungs, than a climate of even the most genial warmth if subject to rapid and extensive alterations. No climate is perfect, not even the much-lauded Madeira—the *ultima Thule* of hectic invalids. Then, why expect that any foreign climate will work something like miraculous results by curing phthisis?" (p. 40.)

SOUTH OF FRANCE. "I am utterly at a loss," says Dr. Burgess, "to conceive how either Aix or Montpellier ever obtained a name for salubrity, as I really know of no place more unfavourable for patients suffering from organic disease of the lungs, than these far-famed and much-frequented dépôts of consumption. No atmosphere, however pure, if occasionally keen and piercing, can prove beneficial for pulmonary consumption; and this is the true character of the air of Montpellier. Provence is the land of dust, from the nature of the soil. Moreover, from the earliest period of its history, the South of France has been famous for its *mistral*, a violent and impetuous wind from the north-west. Leaving the dusty roads out of the question, the rapid and extensive variations of temperature, met with in Provence, are more than sufficient to make that part of the continent shunned by consumptive invalids. There is actually no part of France in which phthisis is so prevalent as in Montpellier and Marseilles; in the latter more especially, where the ravages of this disease are very great." (p. 43-47.)

NICE. The character of the climate of Nice is determined by the manner in which the town is almost surrounded and protected on every side, excepting the south, by that part of the Maritime Alps called Amènes. On the south, it is open to the Mediterranean and its capricious winds. The climate very closely resembles that of Provence; its modification depending upon the circumstance that it is screened from the north wind by the surrounding heights. Hence the cause of its luxuriant vegetation, which in some parts quite equals that of the tropics. The mountainous semicircle is unfortunately interrupted in some parts, which admits the winds most unfavourable for consumptive invalids. These winds sweep down the valleys with great impetuosity, so that vegetation as well as invalids soon show marked signs of their injurious effects.

As Bath may be said greatly to resemble Nice in its sheltered situation, we shall give the mean annual duration of its most frequent winds, contrasting them with the same winds at Nice.

NICE.	BATH.
125 South	35
80 East	37
52 North	15
50 West	67
30 South east	30
337	184

In Bath, the most frequent wind is the balmy south-west, which blows, on an average of ten years, on 101 days per annum.

Amongst the occasional winds that visit Nice, is the north-west, or *mistral*, which even the mountains cannot shut out. This wind is considered the most violent and impetuous of all the winds prevalent in the Nicene valley. Its duration is uncertain; it may continue from three to nine days at a time, or it may disappear in twenty-four hours. In winter, it blows as frequently as the north-east, the west, and the north, the prevailing winds of the season. In autumn, it blows more frequently than the two other autumnal winds, the north and east. Its great prevalence during the winter and autumn exercises a most injurious effect upon the climate, and shows the folly of consumptive invalids seeking at Nice the advantages of a mild temperature and calm atmosphere during those seasons.

"But one of the greatest vices characterizing the climate of Nice, if not the greatest, is the remarkable difference of temperature noticed between day and night, in the sun and in the shade. The land winds prevail during the night, the maritime during the day; the former cold and dry, the latter soft and humid. As soon as the sun rises in the horizon, the humidity commences to show itself in the atmosphere; whilst, on the contrary, when the diurnal winds cease and the sun sets, the above hygrometric condition of the air disappears." (p. 52.)

Mons. Roubaudi estimates the mean annual fall of rain at twenty-six inches; the greatest fall in his observation being forty-five. The annual mean for Bath is thirty-one; the greatest amount during the ten years ending 1851, occurring in 1848, when it reached forty-three; the lowest in 1844, when it was twenty-five.

"There is another circumstance connected with the change of wind which augments the evil. A violent struggle frequently occurs between the maritime and continental winds; the result is a violent atmospheric commotion, the effects of which are felt in every part of the valley. During the existence of this phenomenon, the temperature becomes as much disturbed as the elements themselves; capricious as the winds which are struggling for pre-eminence, it indicates, within a short space of time, heat and cold, with all the intermediate changes. The transition is frequently accompanied by a perfect hurricane, during which violent thunder storms take place, and the valleys are swept by impetuous gusts of wind." (p. 53.)

In reference to this part of our subject, it is worthy of mention, that in the ten years ending with 1851, only twenty-five gales of wind occurred in Bath, and that the whole of the year 1849 elapsed without any; the mean annual number of days in which the wind reached 3 in the scale being 2.3, and that the maximum number was 5 during the years 1843 and 1847.

"A third form of the transition state at Nice, still more injurious to invalids, is, as M. Carrière remarks, worthy of notice. During the alternations from cold to heat and from heat to cold, morning and evening, the humidity suspended in the air and precipitated to the earth produces the following effects: the dew which falls in the evening is often extremely chilly, so much so as to penetrate the clothing in the same manner as occurs in part of the Italian coast. The hoar frost, which covers the earth in the early part of winter, continues after sunrise, producing a hazy state of the atmosphere, and impregnating the soil with moisture. The mornings and evenings are often treacherous, even when the climate seems in its most favourable condition. Nor is its climate so dry as it is described; the land winds which prevail during the night are no doubt dry, but then the maritime winds of the day are humid. M. Carrière cannot understand why the English prefer Nice to other parts of the continent of a milder and more favoured climate, unless it be from the circumstance of the English disease (pulmonary consumption) being generally of a scrofulous nature. Nevertheless, he adds, the mortality annually amongst the English at Nice is sufficiently discouraging to deter other hectic invalids from going there." (pp. 53-4.)

M. Valeri says: "There are certain maladies against which the climate of Nice, far from being efficacious, as imagined, is mortal. Thus, every year's experience tends to prove that it hastens the end of persons attacked with pulmonary consumption." Dr. Meryon, who resided and practised at Nice, thus writes: "You know how treacherous the climate is, alluring you out of doors with a brilliant sun, and then attacking you with a cold, piercing wind,

that neither cloth nor flannel can keep out. Had I leisure, I could collect facts to prove that there are more natives (not strangers, but inhabitants born in the place) who die of consumption in Nice, than in any town in England of the same amount of population. The bills of mortality give one-seventh of the deaths from phthisis." Dr. Burgess concludes his chapter with the remark: "But enough has been shown, I think, respecting that climate, to demonstrate that one more favourable for consumptive patients might easily be found within the British Isles."

It will be seen from the few meteorological facts in relation to Bath which we have quoted, how far superior its situation is to that of Nice; that it is freer from sudden changes of temperature, more equable in its climate; that both possess an equable amount of rain, or nearly so; that in the one the moisture is accompanied with heat, and in the other with a coolness highly grateful to the feelings without being cold; for, as Dr. Burgess observes, a patient with an ulcer in his lung does not want an atmospheric poultice of heat and moisture to promote suppuration, for it is not heat but an *equability of temperature*, even if it is of a low range, that is needed by the class of invalids referred to; and wherever an approximation to that quality can be found, there should the consumptive reside.

We must leave Dr. Burgess's interesting and highly favourable remarks upon the climate of SWITZERLAND to the readers of his work, and proceed with him in his review of the climates of Italy; endeavouring to show that even in that sunny land there are but few if any places, which can be confidently recommended as a winter residence for the consumptive invalid.

MILAN, he says, though not generally recommended, is much frequented by this class of patients, on their way to the south. From lying upon a plain, it is but indifferently sheltered from the various winds. The south has to cross the Apennines; the west and south-west are modified in their character by the line of the Alps; and the upper valleys of this range admit freely the north and north-east winds into the plain in which Milan is situated. On the side towards the Adriatic, from the north to the south-east, the coast is altogether exposed, which enables the various winds to sweep the plain without interruption. The thermal changes thus produced are explained by M. Carrière in the following manner: "The sea, and the open country corresponding with it in the southern region of the Peninsula, admit of the free passage of the temperate and humid winds, which during their transit sink in point of temperature, but gain in that of humidity." Thus, the west winds cool the air in place of softening it, and condense the vapour. They cause a fall of rain without rendering the atmosphere mild. The north winds, colder, more rapid, and more frequent, are those which establish fine weather. The south winds do not possess the same temperature or the same hygrometric conditions, which are their characteristic conditions along the Mediterranean coast. The climate is decidedly cold; the mean number of days on which snow fell during a period of sixty-eight years was nearly eighteen. The maximum was twenty-one between 1820 and 1830. The rain falls abundantly; the mean is, however, but 62; the maximum, 81.

It is only necessary to walk through the streets of Milan, to see the morbid effects upon the countenances of the people produced by the hygrometric condition of the atmosphere, and the sudden transitions from humidity to dryness and cold. It is hence very evident, that consumptive persons can derive no benefit from the climate, but that they may sustain a great amount of mischief.

CENTRAL LOMBARDY. The entire plain of Lombardy, says M. Carrière, is irrigated so profusely, that, with the exception of Holland, it has not in this respect an analogue in Europe. A number of rivers and lakes, a network of canals, and finally the artificial marshes produced for the cultivation of rice, occupy the whole territory. When the waters retreat, the saturated soil and mud become *foci* of miasma, which would be in a still higher degree dangerous but for the care bestowed upon the cultivation of the soil.

Dr. Burgess is clearly of opinion that a locality equally injurious to patients suffering from consumption could not be found in any part of the United Kingdom or central Europe.

Dr. Webster thus describes the climate of Pavia in a letter to Dr. Burgess:

"For many weeks during winter, the fogs are so dense, that the sun is scarcely visible. For months real sunshine was unknown. Mantua is not better as regards climate, nor is Verona an exception."

VENICE. Dr. Burgess speaks more favourably of this city than of any other in Italy, for its mildness and equability of temperature. He devotes an exceedingly interesting chapter to its examination, quoting largely from the observations of previous inquirers. So far, he observes, as consumption is concerned, the alleged sanative effects of its climate are purely imaginary, as shown by the prevalence of phthisis amongst the inhabitants.

GENOA. Of this city Dr. Burgess speaks unfavourably; for he justly says that, when Cevasco, prepossessed in favour both of the city and its climate, admits that pneumonia, hæmoptysis, catarrh, and consumption, are amongst the most frequent diseases, it becomes pretty evident that Genoa cannot prove a very favourable halting-place for phthisical patients, at whatever stage their complaints may have arrived.

FLORENCE. In no part of England could a climate be found more unfavourable for consumptive invalids than that of Florence, a town built in a deep ravine, almost surrounded by the Apennines, and intersected by a squalid river. During winter, intense cold sometimes prevails in Florence, more so than in England. The surrounding hills are frequently covered with snow, and a sharp, cutting wind from the Apennines often blows like the blasts of Siberia.

PISA. Dr. Burgess devotes an entire chapter to this city, which he describes as the great central depot for foreign consumptive invalids throughout Italy. It is impossible to analyze his description without doing him injustice. He says, "you cannot walk through its streets, without mourning over the traditionary delusion which has enticed so many natives of England to seek a renewed lease of life in a foreign country, to find only an Italian grave." M. Carrière, who, as Dr. Burgess well observes, rarely advances anything against the Italian climate in relation to phthisis, that he can possibly avoid, admits the climate of Pisa to be by no means so favourable for consumptive invalids as rumour and tradition would lead foreigners to suppose.

ROME. We would strongly advise a perusal of Dr. Burgess's remarks upon the climate of the Eternal City to every person who contemplates a sojourn in it during the winter. He says: "I could hardly recommend those who suffer from affections of the chest, to pass a winter in Rome, as I fear they would too often suffer from the inconveniences of a cold latitude, without being able to meet with suitable preservatives against cold and damp." "I believe," says he, "that the climate of Rome is not adapted for pulmonary consumption in any form whatever;" and we firmly believe that no one, after reading Dr. Burgess's remarks upon its coldness, damp, and malaria, can possibly differ from him in his unfavourable opinion.

NAPLES. Dr. Burgess concludes his work with the following observations:

"The climate of Naples is the most dangerous throughout Italy to persons suffering from diseases of the respiratory organs. From the preceding summary of the characters manifested by the Italian climates, it will be seen, that, however useful they may be in other complaints, one more likely to act beneficially in pulmonary consumption might easily be found within the United Kingdom."

In concluding our remarks upon Dr. Burgess's valuable work, we would urge upon our fellow-members the importance of the study of medical topography. It forms, indeed, one of the prominent objects for which the Association was founded; and yet, how little has been done during its twenty-one years' career. Those only who have had the

courage to pursue the topography of a district can tell the difficulties which environ the task. The absence of correct observations extended over a period of years, the difficulty of access to both private and official sources of information, and the unremitting attention required, render it almost too great a task for one individual; but why not associate together the members of our various branches in the different investigations required in each locality, so that by a division of labour a work might be compiled on the climate of England, which, while it would be honourable to British medicine, would at the same time confer honour upon the Association? There is not one branch of physical science upon which we as a nation are so ignorant as upon the climate, meteorology, and natural history of our own country; and we think that great good would result from the formation, at the next annual meeting, of a topographical committee, whose duty it should be to compile a series of forms suitable to each portion of the inquiry, which might be circulated with advantage; so that each associate might contribute something to the general stock.

A few words more upon the climate of our own country, and we have done. There are many spots, more particularly in the West of England and South of Ireland, which possess great advantages as residences for pulmonic invalids, but whose merits rest on hearsay rather than on scientific testimony. Dr. Burgess largely quotes scientific data in reference to the foreign climates discussed, and rebuts much of their vaunted celebrity. He is of opinion that many places in the British Isles might be found equally suitable; and we agree with him; but their advantages must bear the test of diligent inquiry and patient investigation, before we can hope to remove the long-established error, that nothing but a removal to Italy, Malta, or Madeira, can avail for the cure of the aristocratic sufferer from pulmonary consumption.

We trust that the wide circulation of Dr. Burgess's volume may tend to dissipate the prevailing mischievous delusions as to foreign climates.

ANIMAL ELECTRICITY; being an Abstract of the Discoveries of EMIL DU BOIS REYMOND, Member of the Academy of Sciences at Berlin, etc. Edited by H. BENGE JONES, M.D. Cantab., F.R.S., etc., Physician to St. George's Hospital. Small 8vo., pp. 214. London: 1852.

To the cultivator of science, and to the physician engaged in active practice, this abstract of the *Untersuchungen über thierische Elektrizität* of Dr. Du Bois-Reymond will be most acceptable; but especially to the latter, as presenting to him, in a condensed form, a lucid sketch of the progress of this branch of physiology from the time of its founder, Galvani, to the present day, and a succinct account, not of the labours merely, but also of the errors and misconceptions, of those who are now gratefully recognized as masters in the brilliant path of electrical philosophy.

The introductory chapter runs rapidly and pleasantly over the course of discovery from the 20th of September, 1786, when Galvani made his eventful observation upon the muscular contraction of animals, to the period of Oersted's grand discovery in 1820, to which most, if not all, of the varied and marvellous economical applications of electricity may be directly traced; a discovery which has furnished us with one of the many striking proofs we possess, of the advantageous results springing from the sedulous cultivation of pure science to the physical well-being of man, and putting to open shame the utilitarian, who with his limited vision would recognize Science so far only as she can immediately minister to his wants and gratifications, sneering at theory, and prosing about practice; forgetful, or rather ignorant, all the while, that a single observation of the student of nature has often—as in this instance of Oersted's remark on the deflection of the needle by a galvanic current—been the foundation and starting-point of a series of discoveries and applications which have exercised an irresistible and marvellous influence on the world's progress.

The galvanometers ordinarily made use of not being sufficiently delicate for the author's purpose, he constructed two of different degrees of sensitiveness, but both exceeding, in this particular, those previously employed by electricians. For his description of these instruments we must refer the reader to the

work itself, instancing only the length of the wire used in constructing the more delicate of the two: it is of copper, measuring 5,584 yards, or 3.17 English miles long, about .0055 inch in diameter, and forming 24,160 coils around the frame. Such an instrument as this necessarily requires the greatest care in guarding it, when in use, from extrinsic influences, ample directions for which are given. The next step is the mode of using the galvanometer to detect electric currents in the organs of animals: this is carefully described. Platinum plates, perfectly clean and homogeneous, are made to communicate with each end of the galvanometer, and plunged into cylindrical vessels of glass or porcelain filled with a saturated solution of common salt; the circuit being completed by connecting the vessels with a syphon-tube, also filled with the saline solution, and closed at either end with bladder. But it is only in the rougher experiments that the animal structures can be dipped directly into the solution, because it would so act on these structures as to seriously vitiate the observations. To meet this difficulty, Dr. Du Bois-Reymond has modified his apparatus by employing cushions of blotting-paper, so as to prevent the possibility of this injurious action, in a manner which is thus described:

"These cushions are made of many layers of fine blotting-paper, swelled with the saturated solution of salt; they rest against the edge of the vessel containing the solution, not only on the edge of the glass, but inside, upon little blocks of wood fixed to the side of the glass. These paper cushions may be called the *conducting cushions*. When these cushions are used, the circuit, instead of being closed by means of the connecting tube, is closed by means of a *connecting cushion*, which is also wet with the saturated solution. To bring the animal part into the electric circuit, the connecting cushion must be removed. Still the animal part must not be laid directly on the conducting cushion, lest such a corroding action should take place as would cause contraction of the muscles, and most rapidly destroy the vital properties of the nerves. To avoid this immediate contact, Du Bois-Reymond places a guard of pig's bladder, perfectly moistened with white of egg, on that part of the conducting cushion on which the animal part is to be laid. Thus on the cushion the guard is laid, and on the guard the animal part."

This is sufficient to show both the care of the experimenter in preventing sources of error, as well as the patient and dexterous manipulation requisite in pursuing observations demanding such great delicacy.

With this apparatus, and the galvanometer already noticed, the author has industriously investigated the phenomena attendant on the contraction of the prepared limbs of the frog, proving the frog-current and the various cognate phenomena to be dependent on one general law governing the muscular current of all animals, so far as these have been experimented on; and the elimination of this one simple general law from a series of observations of the most careful and guarded kind, is the most valuable of all the results which Du Bois-Reymond has attained. It is difficult, without the help of the plates and diagrams of the text, to describe these striking experiments; but we must make the endeavour. Let, then, the circuit, including of course the galvanometer, be complete, excepting the space between the two cushions of blotting-paper; now if a muscle, such as the *adductor magnus*, be placed so that one of its tendinous extremities shall be in contact with each cushion, no current is produced, and no deflection, or the very slightest, is observable; but bend one end of the muscle up, so that whilst the *tendinous extremity* presses against one cushion, the *red flesh* is in contact with the other, a considerable deflection ensues, showing the existence of a current in the muscle from the tendinous extremity to the place of contact of the fleshy part of the muscle on the other cushion. Now if a transverse artificial section of the muscle be made, and this section rest against one cushion, whilst the natural longitudinal section is in contact with the other, powerful action is at once excited, and the needle remains fixed at the checks of the galvanometer, the current in the muscle invariably being from the transverse to the longitudinal section; "hence it may be concluded that *every point in the natural or artificial longitudinal section of a muscle is positive in relation to the transverse section, whether natural or artificial*." It appears that differences exist between the points of the transverse section, those points lying near the centre of the section being negative in respect to those at the exterior; the current, however, being far weaker than that obtained between the transverse and the longitudinal section, which latter, like the transverse section, is not homogeneous at all its points.

The chapter succeeding the descriptions of these expe-

riments, and the announcement of this important law, is sadly out of place in an abstract; it would have been quite sufficient if the Editor had assigned the palm of discovery to his author, without dragging in the particulars of the disputes with Matteucci, a defect observable in other parts of the book. The next point of importance treated of is the influence of contraction on the muscular current, which the author is convinced is sensibly diminished during a powerful and lasting act of contraction. Various subjects in connexion with the muscular current are then brought under the reader's notice, and the treatise closes with an examination of the much vexed question of the identity of the nervous power with electricity. In this investigation, Dr. Du Bois-Reymond has been equally happy as in the previous researches; showing, not only from experiments on the ischiatic nerve of a frog and of a rabbit, that a current exists in the nerves, but that it is evidenced in the same direction as in the muscles, the length and thickness of the nerves increasing the electro-motive force, just in the same way as they act with the muscles. Enough has been said to show the value of these researches, and to induce such of our readers as may be interested in this subject to peruse this abstract of the present state of knowledge on a very obscure and difficult subject, for which, in this compendious and portable form, we have to thank Dr. Bence Jones.

THE MODERN PRACTICE OF PHYSIC: exhibiting the Symptoms, Causes, Prognostics, Morbid Appearances, and Treatment of the Diseases of all Climates. By ROBERT THOMAS, M.D. Eleventh edition: thoroughly revised, corrected, and, to a considerable extent, re-written, by (the late) ALGERNON FRAMPTON, M.D. Cantab., Physician to the London Hospital. Two volumes, pp. 755 & 564. London: 1853.

No digest of practical medicine ever enjoyed a greater popularity than the work of Dr. THOMAS—a circumstance which may be in a great measure attributed to its excellent plan and abundance of useful formulæ for prescriptions. The young practitioner finds the value of good formulæ, and he naturally prefers a work which, along with general precepts, enters into details regarding the proper doses and most convenient combinations of medicines: and as every one, in starting in practice, must have at least one text-book of medicine, it is not difficult to account for the rapid sale of so many editions of the work now before us. The merits of the treatise, however, are not limited to those at which we have hinted; for we find it as comprehensive, as clear, and as satisfactory a book of instruction for students and practitioners as any work of a similar description with which we are acquainted.

At the period of Dr. FRAMPTON'S death, in December 1851, the first volume of this edition was printed off, or in the hands of the printer; and a considerable portion of the second volume was ready for the press. The subjects which Dr. FRAMPTON had not finally prepared, were entrusted to several accomplished friends of the deceased, who have ably and faithfully carried out his plan.

PHYSICIAN'S, SURGEON'S, AND GENERAL PRACTITIONER'S VISITING LIST, DIARY, ALMANACK, and Book of Engagements for 1853. London: 1853.

We have used Mr. SMITH'S Visiting List every day for the last three years; and we can cordially recommend it as by far the best thing of the kind which has yet been contrived. In its present improved form, we really have no fault to find with it. The various sizes render it equally suitable to large and small practices.

PERISCOPIC REVIEW.

MIDWIFERY AND DISEASES OF WOMEN.

ALBUMINURIA IN PREGNANT FEMALES: ITS SYMPTOMS, CAUSES, RESULTS, AND TREATMENT.

THE occurrence of albuminuria during pregnancy has in late years engaged much attention, both in this country and on the continent. We therefore propose to give a digest of some of the principal essays which have recently appeared on the subject. The titles of the works from which we have gleaned our information are subjoined according to the chronological order of their publication.

1. LEVER, John C. W., M.D. Cases of Puerperal Convulsions, with Remarks. *Guy's Hospital Reports*, 2nd series, vol. 1, p. 405.

2. DEVILLIERS and REGNAULT, MM. Recherches sur les Hydrophisies chez les Femmes Enceintes. *Archives Génér. de Médecine*, 1848.

3. CORMACK, John Rose, M.D. Dependence of Puerperal Convulsions on Toxæmia; Explanation of the more common occurrence of Renal Convulsions in Primiparæ. *London Journal of Medicine*, June, 1849.

4. BLot, M. Hippolyte. De l'Albuminurie coïncidant avec l'Eclampsie. *L'Union Médicale*, Oct. 10, 1850.

5. LITZMANN, Professor (of Kiel). On Bright's Disease,* and Convulsions before, during, and after Labour. *Deutsche Klinik*, May, June, and July, 1852.

6. SIMPSON, Professor J. Y. Albuminuria in Puerperal and Infantile Convulsions, etc. *Monthly Journal of Medical Science*, October, 1852.

7. COSTILHES, Dr. Case of Convulsions occurring seven hours after Delivery. *Gazette Médicale*, October 9, 1852.

Albuminuria in pregnant and parturient women has generally been noticed in reference to convulsions, for the most part occurring in primiparæ. The investigations of Dr. Blot and Professor Litzmann were made with a view to determine its frequency during pregnancy.

Dr. Blot found it present in 41 cases out of 205, primiparæ being chiefly affected.

Dr. Litzmann has examined the urine of 131 females: 79 during pregnancy, 80 during labour, and 80 after delivery. He found albumen present in 37, and absent in 95. Of the 95, whose urine contained no albumen, 53 were primiparæ, and 42 multiparæ. Of the 37 who had albuminuria, 26 were primiparæ, and 11 multiparæ; two were pregnant with twins. Of the 37, the urine of 16 was found to be albuminous during pregnancy: in 10 of these the albumen continued some days after labour: in 4 it disappeared before confinement. In 4 women in whom albuminuria was found after labour, it had probably existed during pregnancy, although the urine had not been examined.

Dr. Litzmann points out that albumen may be present in the urine from vesical catarrh. This can sometimes, but not always, be referred to pressure on the neck of the bladder during labour. It is distinguished from renal albuminuria by the absence of fibrinous casts of the uriniferous tubes, which he found in most of the cases in which the albuminuria had reached a high degree, towards the end of pregnancy.

Symptoms. Nothing certain is known as to the time when the renal affection commences. It usually begins insidiously, and increases slowly: its commencement is, perhaps, rarely denoted by any remarkable symptoms. The only constant sign by which renal disorder during pregnancy is denoted, is the state of the urine. Dr. Litzmann has not observed albumen before the eighth month; but Devilliers and Regnault found it in the sixth. The quantity of albumen is usually very conspicuous, and increases as the time of delivery approaches. In proportion to the intensity and duration of the morbid process in the kidneys, are found casts of the uriniferous tubes in greater or less quantity, the epithelium lining them being sometimes normal, sometimes in a state of fatty degeneration. In the milder cases, the tube-casts are often found just at delivery, or soon after. Careful examination will probably in all cases detect a not inconsiderable diminution of the quantity of urine. Pain in the loins is not diagnostic; but Dr. Litzmann has found tenderness on pressure over the kidneys in nearly all cases—this being absent in pregnant females whose kidneys are unaffected. Dropsy, in many cases, is entirely absent; but more frequently it is considerable. It is favoured by an impoverished state of the blood, and by local impediment to the circulation. The true succession and influence of these causes cannot always be determined. Oedema usually commences in the last four months of pregnancy, mostly in the lower limbs, ascending gradually to the knees, or even higher. Sometimes it is limited to these parts; but oftener extends to the abdomen, and more rarely, as in a case recorded by Dr. Litzmann, to the *labia majora*. A most unequivocal sign of renal disease is oedema of the upper part of the body, the hands, arms, and face; but Dr. Litzmann has several times seen this

* The term "Bright's disease" is very frequently used by continental writers in a wider sense than by the English. They appear to ascribe to it all conditions of the kidney in which albumen is found in the urine, from simple congestion up to advanced structural disease.

when there has been no albumen in the urine, although there have sometimes been even headache and transient disturbance of vision. The oedema in these parts generally appears towards the end of pregnancy: sometimes only after the patient has been some time in bed, disappearing when she arises. In the lower limbs the skin is usually pale and cool, and the finger leaves a depression; in the face the skin is generally warmer than usual, the cheeks red, the eyelids injected, and the skin elastic. The oedema sometimes appears and disappears irregularly; sometimes it increases up to delivery, and then disappears without leaving any trace of renal disease; and that even when the albumen in the urine has gone on increasing.

Mechanical Origin of Albuminuria during Pregnancy. In his paper, of which we have given the title, Dr. Cormack ascribes the frequency of albuminuria (and of convulsions) in primiparae to the greater tenseness and rigidity of the abdominal parietes; the gravid uterus being therefore more apt, by its inward pressure, to produce renal congestion. The tight girdling of the abdomen, often practised by those who become pregnant out of wedlock, probably acts powerfully in producing the same effect; and may, as Dr. Cormack suggests, explain to some extent, why unmarried primiparae are more liable than married primiparae to puerperal convulsions. When convulsions occur in subsequent pregnancies, Dr. Cormack would, believing them to be chiefly toxæmic, ascribe them either to imperfect distension of the abdominal wall, from incomplete gestation on former occasions, to excessive muscular development, to renal disease, or to excessive volume of the uterine tumour, including plural pregnancies. He says that "the gravid uterus, or other tumour, pressing on the renal veins, or in any way seriously impeding the return of blood from the kidneys, must induce more or less inability on their part to perform their emunctory office."

Dr. Litzmann adopts a similar explanation of the occurrence of albuminuria in pregnancy. "In favour of the mechanical explanation of the occurrence of albuminuria in pregnant women, may be adduced its predominance in primiparae—a fact recognised by all observers. The tight and unyielding abdominal wall most naturally causes the uterus to press more powerfully on the structures behind and above it." Two of his patients who had albuminous urine, were pregnant with twins: in others there was a large quantity of liquor amnii, or a large child, or both. In one case, there were periodical spasmodic contractions of the abdominal muscles, especially the recti, pressing the uterus against the spine; in four cases the pelvis was narrow.

Dr. Murphy, in his *Lectures on the Principles and Practice of Midwifery*, objects to Dr. Cormack's explanation—"First, that the pressure exercised by the gravid uterus is of too gradual a nature to cause any great amount of congestion, and the circulation has sufficient time to find new channels for itself, and relieve the emulgent veins. Secondly, the period of the attack would be more frequently at the last month of gestation, or the commencement of labour, than we know it to be." (pp. 379-80.) With deference to so high an authority in matters obstetrical as Dr. Murphy, we do not feel convinced by his arguments. In the first place, the number of cases in which albuminuria has been detected during pregnancy, proves that there must be some impediment to the renal circulation; and we must probably take into consideration not only the unyielding abdominal walls, but also the hindrance to the compensatory circulation through the mammary and epigastric veins, produced by tight stays and other articles of female apparel. Secondly, we find Dr. Murphy himself stating (p. 368)—and this is in accordance with general experience—that the most frequent period of puerperal convulsions is "on the approach, or during the progress, of labour."

Relation of Albuminuria during Pregnancy to Renal Disease. In his paper already quoted, Dr. Cormack, after referring to the frequent abrupt occurrence of convulsions and death in the course of Bright's disease, writes as follows:—"It is quite plain that a pregnant woman, labouring under Bright's disease, even in an early stage, must in this way run a tenfold risk of convulsions. If she have an ovarian tumour, or any other mechanical predisposing cause to renal congestion, besides the gravid uterus, her risk will also be great. In her, too, delivery will hardly bring exemption from the danger of toxæmia from renal non-elimination. Dr. Simpson said, in 1843, that he had been accustomed to teach in his lectures that 'patients attacked with puerperal convulsions had almost always albuminous urine, and hence probably granular renal disease.' This remark of Dr. Simpson's, with deference to so high an authority, I must dissent from. Under proper management, the majority of those

affected with puerperal convulsions quickly and perfectly recover, and in future pregnancies are very rarely affected. Undoubtedly women who have structural disease of the kidneys, are pre-eminently liable to renal congestion, and consequent toxæmia; but then oedema, albuminuria, and convulsions, are not, in the puerperal woman, pathognomonic of any organic disease of the kidney, though in the *fatal* cases we may expect them to be often present. In three fatal cases of puerperal convulsions, Dr. Simpson found, on dissection, a great amount of renal disorganisation. Albumen was looked for in the urine during life, but was not found."

In the *Monthly Journal of Medical Science*, for October 1852, Dr. Simpson expresses a greatly modified, and we think more correct opinion, on the subject. He says:—"Usually, the state of albuminuria which leads to puerperal convulsions is a transitory morbid condition, from which the patient recovers within the course of a few days after delivery; and the affection does not depend on, or result in, any actual change of structure in the kidney."

Professor Litzmann, in the *Deutsche Klinik* for July 17th, says: "The anatomical changes which are found in the kidneys of those pregnant females who have died with Bright's disease, denote, for the most part, only the earlier stages. Even Devilliers and Regnault have not felt themselves justified in assuming the existence of albuminous nephritis in all cases. They generally found the kidneys enlarged in volume; the capsule was rarely adherent. In two cases only was there an undoubted granular appearance in the organ. In three cases, inconsiderable enlargement of the organ was accompanied by slight hypertrophy and paleness of the cortical layer. In two other cases, the cortical substance was highly coloured, while the pyramidal portion was in some parts injected, in others pale. In one case, the deep red of the hypertrophied left kidney contrasted strongly with the paleness of the right; and in another, the hyperæmia and swelling were limited to the cortical substance. Cazeaux and Rayer have observed generally the second, sometimes the third, and in one case the fourth form of the albuminous nephritis of the latter author. In all the cases examined by Frerichs, he found fibrinous casts in the urinary passages and in the urine. In one of the cases described by me, the changes in the kidneys had proceeded unusually far; and this might have been inferred from the severity of the symptoms during life, and the presence of tube-casts in the urine."

Dr. Litzmann believes that there is no case in which renal disease, continuing after delivery, has been proved to have commenced during pregnancy; although women have died of chronic disease of the kidneys some time after labour. It is, perhaps, probable that in certain rare cases the renal affection during pregnancy becomes so intense and extensive, that the impeded circulation is not restored after delivery; on the other hand, there is no doubt that women who have once suffered from renal congestion when pregnant, are liable to its return when again in a similar condition. It by no means follows that the disease should amount to uræmia, for this is not always present even in primiparae.

There is, we think, ample evidence to prove that albuminuria during pregnancy is far from being an indication of *permanent structural renal disease*: but if disease of the kidney already exist, the danger to the patient will be much increased, while delivery will not cause the albumen to disappear from the urine. Dr. Murphy inclines to the belief that "the albuminous state of the urine, taken in connexion with the oedematous condition of the surface, would indicate the existence of renal disease in many instances." Temporary congestion is no doubt disease, in the strict sense of the term; but if Dr. Murphy means permanent structural disease, we think that the statistics of Blot and Litzmann, as to the frequency of albuminuria during pregnancy, as well as the common fact of recovery from it, militate against his opinion.

Prognosis. The prognosis in cases of albuminuria during pregnancy, is, according to Dr. Litzmann, more favourable than when the affection occurs under other circumstances. The danger principally arises from poisoning of the blood with urea: but not unfrequently the renal affection runs its course without any threatening symptoms, so that it might be overlooked, unless the urine were examined chemically and microscopically. The albumen commonly disappears after delivery: often within forty-eight hours. During labour, the secretion of urine commonly increases, as does also the number of fibrinous tube-casts; after delivery, these increase for a time, but soon disappear, even while albumen is still present. The oedema disappears, as the quantity of urine increases.

Relation of Albuminuria to Puerperal Convulsions. The frequent occurrence of albuminuria in connexion with puerperal convulsions, has been fully demonstrated by the observations of Drs. Simpson, Lever, and others. MM. Devilliers and Regnault declare that "chez toutes les femmes éclamptiques, on trouve de l'albumine dans les urines. Cette règle ne nous a pas encore paru souffrir d'exceptions". Reasoning on these and similar statements, Dr. Cormack says: "If it be a fact, then, that albuminous urine and anasarca—the characteristic signs of congestive kidney—be so common in puerperal convulsions, as to be regarded, by the first and most recent authorities, as their constant concomitants, it may, I think, be very safely inferred that the renal congestion is the cause of the convulsions; or, to be more explicative and precise, that the convulsions are direct toxicological effects on the nervous centres, produced by poisonous substances which the unembarrassed kidney could throw off with the urine, but which the congested kidney cannot excrete." And he refers the greater frequency of convulsions in primiparæ to their greater liability to congestion of the kidney, from the mechanical causes already described.

Dr. Litzmann writes as follows: "The principal danger in Bright's disease occurring in pregnant females, arises from the uræmia, which is usually indicated by convulsions. Of the causal connexion between Bright's disease in pregnancy, and convulsions, no one, who will observe it, can remain in doubt; although I by no means deny that exceptional cases of eclampsia may arise from other causes. Lever has observed a case depending on inflammation of the meninges. The first authors who pointed out the occurrence of albuminuria in puerperal convulsions, as Lever, etc., recognised the analogy of the convulsions to the cerebral disturbances occurring in common cases of Bright's disease; and expressed their conviction that they were dependent on the noxious influence of blood poisoned with urea. But they, as well as Devilliers and Regnault, failed in discovering urea in the blood of convulsive patients.* Frerichs, from his observations on patients and experiments on animals, has asserted that the symptoms of uræmic intoxication in Bright's disease do not depend on the existence of urea, as such, in the blood, but on its transformation within the vessels into carbonate of ammonia, under the influence of a peculiar ferment. My observations on the convulsions of pregnant females entirely agree with this theory. In one of my cases, the presence of ammonia in the blood was not ascertained by conclusive evidence; but in three other cases there could be no doubt of its presence, as carefully repeated experiments always gave the same result. On the other hand, when there were no symptoms of uræmic intoxication, though albuminuria existed, the blood appeared free from this poisonous admixture. I have not found urea either in the blood, nor in the serum resulting from scarification of the oedematous parts. In only one case could I detect ammonia in the expired air. In one case just after delivery, the sweat on the forehead had an alkaline reaction".

Although puerperal convulsions are often connected with renal congestion, it by no means followed that they are an inevitable result. Devilliers and Regnault observed eleven cases of convulsions in twenty pregnant females who had albuminuria; Blot found them present in only seven cases out of forty-one. Dr. Litzmann found seven cases with uræmic symptoms, five of whom had convulsions, in thirteen cases described by him.

Other effects of Toxæmia from Renal Congestion during Pregnancy. Dr. Litzmann observes that certain other phenomena, principally connected with the nervous system, which have been usually considered as premonitory of convulsions, may be themselves the only effects of toxæmia; and that this probably occurs when the quantity of urea in the blood is but small. Headache is generally present when there is œdema of the face; and is then probably most frequently the result of simple congestion. The most marked symptoms of uræmia are disturbances of the senses, especially of vision. The patients complain of muscæ volitantes, or see objects coloured yellow or red; more frequently they see dark figures, or only see the half of objects; sometimes there seems to be a dark veil over objects; or the patients may be quite amaurotic. These symptoms are sometimes only momentary: in other cases, when they are more intense, they continue for hours, and days. In the amaurosis, the pupils are little or not at all dilated; but they obey sluggishly, or are unaffected by, the stimulus of light. Amaurosis usually appears before or during labour; but sometimes subsequently. Coma or convulsions are apt to follow it. It is probable that most of the cases of amblyopia and amaurosis,

which occur at the end of pregnancy, disappear after labour, and return in subsequent pregnancies, are to be referred to this head.

Noises in the ears, which authors have named among the forerunners of eclampsia, have never been observed by Dr. Litzmann.

Nausea, a sense of choking, and vomiting, are among the most constant symptoms. The vomiting is not always an indication of uræmia, but is sympathetic with renal irritation, or perhaps more frequently with congestion of the brain. Its connexion with uræmia must be decided by chemical examination of the vomited matters.

When uræmia is developed for the first time during labour, there is often a dulness of the intellect, a certain wildness or melancholy of the patient, and remarkable restlessness and impatience during the labour pains: there frequently are rigors, returning with each pain, (Hamilton, Mc Clintock and Hardy); the pulse is more frequently slow than accelerated.

Eclampsia rarely occurs without any premonitory symptoms: and when it does, it probably arises from a sudden impregnation of the blood with a large quantity of urea.

Dr. Costilhes (*Gazette Médicale*, October 9, 1852,) points out that long continued albuminuria, by impoverishing the blood, may give rise to hæmorrhage from the uterus or other parts of the body.

Treatment. Dr. Cormack writes as follows. "The prophylaxis of renal puerperal convulsions must evidently embrace an avoidance of too long continuance in the supine position; an easy corset, giving free play to the lungs, and not pressing back the womb; moderate exercise; regularity and sufficiency of the alvine evacuations; and a good state of the skin. Mental excitement must also be avoided, as it might, even with a moderately poisoned state of the blood, be the immediate cause of convulsions." In the treatment, he gives the following as the leading indications.

1. Remove pressure from the renal vessels, by interdicting the supine posture, and by unloading the bowels; and, when safe, by emptying the uterus.

2. Relieve congestion of kidneys by purging, by cupping in the loins, or by general bleeding.

3. Venesection, if apoplexy be threatened.

4. Calmatives to soothe the excited nervous system.

The first two of these measures have more especial reference to the condition of the kidneys; the last two to the cerebral symptoms.

Dr. Litzmann observes, that the renal congestion cannot be relieved before delivery: but that it may be mitigated, and more unfavourable symptoms averted, by timely measures, especially the removal of all causes which may assist in impeding the circulation through the abdominal vessels. It is thus important to obviate the constipation so common in pregnant women: and in one case, Dr. Litzmann has not only seen all the symptoms recede, but the albumen in the urine diminish. If the renal disease have set in suddenly, and is accompanied with much pain and tenderness, local bleeding is indicated. It is doubtful whether benefit would be derived from diuretics or astringents before labour: but on this point he has had no personal experience.

With regard to the blood-poisoning, when symptoms of an impoverished state of blood occur, a strengthening diet, with iron, cinchona, etc., are indicated.

In the unmistakable symptoms of cerebral congestion, which almost always accompany uræmia, local depletion and cold applications, timely applied, usually give quick relief, and the secretion of the dry skin may be rendered active by bathing with warm vinegar. Frerichs, acting on his theory of the conversion of urea into carbonate of ammonia within the blood, gives acids, especially the benzoic; and Litzmann has given the benzoic and citric acids, he believes sometimes with favourable results.

If convulsions occur, general bleeding is indicated in strong plethoric individuals. But if the renal disease have lasted some time, and hydræmia is present, this treatment is likely to injure; local depletion must then be employed and repeated as may be required. Large doses of acids must be given, cold wet cloths applied to the forehead, and the extremities bathed with warm vinegar. It is often useful to empty the intestinal canal: but Dr. Litzmann cautions his readers against being led to give large doses of drastics and mercurials; and he acknowledges himself not blameless in this respect, with regard to a case related by him. If all these remedies fail, labour must be induced: and after birth, the state of the kidneys must be carefully watched. Mild diuretics are now likely to be useful, but if albumen continue to be present in the urine, the case is to be regarded as one of chronic Bright's disease.

* In Guy's Hospital Reports, 1849, vol. vi, chap. 12, Dr. Lever appears to have found urea in the blood of an eclamptic female.

MR. I. B. BROWN'S OPERATION FOR THE REMEDY OF RUPTURED PERINEUM.

The principle on which Mr. Brown's operation is founded, and the success which appears to have attended it, entitle it to be well received by obstetric surgeons. We quote the following account from the published proceedings of a recent meeting of the Medical Society of London:—

"The patient should be placed in the position for lithotomy; the knees well bent back upon the abdomen by an assistant to each leg; the parts around should be carefully cleansed of hair, by shaving; then each assistant should hold the sides of the vagina and perineum, so as to insure sufficient tension for the operator to make a clean incision with a scalpel down into the vagina, about three-quarters of an inch on each side, removing carefully and thoroughly the mucous membrane. Both sides being done, there will still remain a space covered with mucous membrane between those two sides, embracing the edges of the rectum where the sphincter is lost; this must also be carefully denuded,—very carefully, because, if there remain the slightest portion of mucous membrane around, or even near to the rectum, then most certainly there will be a recto-vaginal fistula after the restoration of the perineum. Some operators, especially on the Continent, have removed the mucous membrane by the scissors, but Mr. Brown stated that that is a long and insecure method, and that the knife will be found quicker and better. As soon as this stage of the operation is completed, the sphincter should be divided; then the legs should be relaxed, and the thighs brought more in apposition, so as to allow the sides of the vagina to be grasped with the forefinger and thumb of the left hand, while with the right the sutures are passed deeply through each side, as deep as the denuded surfaces of the vagina; the first backwards, as near the rectum as possible without piercing it; the second and third in the same way: the length of the incision should correspond with the scar of the ruptured surfaces; the sutures are double, so as to allow the quill, or, more properly, the piece of elastic bougie, to pass through each suture on both sides. Mr. Brown prefers twine to silk for the sutures, because it is less irritating, and produces, therefore, less suppuration. The forefinger of the right hand should then be passed into the vagina, and the forefinger of the left hand into the rectum, so as to ascertain that there is no opening. After securing the three sutures firmly to the bougies, it is advisable to bring the edges of the incised surfaces together by three or four interrupted sutures; and if this be carefully done, union of the skin will quickly take place, and materially facilitate the adhesion of the deeper surfaces. It has been asserted by many accoucheurs of the highest eminence, that, if the operation be performed immediately after the accident, no good will result, as the lochia will flow in between the surfaces, and thus prevent adhesion and union. This was the opinion entertained by Trogher, who states, in the seventh volume of the *Vienna Journal*, for 1851, among other conclusions drawn from sixteen cases, 'that a favourable issue could only be expected where there was a very moderate flow of lochia': also, 'that it was impossible to protect the margins of the wound from the injurious influence of the lochia'. Mr. Brown believed that these objections are removed by dividing the sphincter; if this is not done, the inner edges of the wound will be gradually drawn apart by the action of that muscle, and the lochia will penetrate; whereas, after division, those edges are perfectly passive, and are steadily kept together by the sutures. Mr. Brown stated, that, for the convenience of discussion, and in order to make his paper more intelligible, he affirmed four distinct propositions, which he hoped to demonstrate by the cases which followed:—Firstly, that the oldest and worst forms of ruptured perineum can be cured by the operation he had already described. Secondly, that the worst forms can be cured by operating immediately after the lesion. Thirdly, that the new perineum is not torn by, or prejudicial to, subsequent parturition. Fourthly, that those forms of rupture where the sphincter is not torn through, should be cured, to prevent prolapsus uteri, etc."

In the discussion which followed the reading of Mr. Brown's paper, several interesting remarks were made by different speakers. Dr. Murphy "was decidedly opposed to—he was almost induced to say, he protested against—the performance of an operation in recent cases as soon as possible after the occurrence of the rupture. It was vitally important for some time after delivery to avoid the accession of inflammation in the

tissues adjacent to the uterus; and if inflammation were set up in the vagina, there was great reason to dread its extension. Besides, it was well known that the laceration of the perineum, which, a few hours after delivery, might appear of formidable extent, would frequently contract, in two or three days, to one of insignificant size, so that an operation practised prematurely, might have been altogether unnecessary. For these reasons, he considered that in all cases of perineal rupture, in which an operation was resolved upon, it would be infinitely better to defer the operation than to practise it immediately after parturition."

Mr. Coulson thought "the chief merit of Mr. Brown's operation consisted, as in most operations, in the perfect adherence to its details. There were four principal features in Mr. Brown's operation to which he would more especially advert. The first, which had been hardly noticed sufficiently in justice to himself by the author, was the large extent of mucous membrane that was pared from the edges of the wound. He (Mr. Coulson) considered this a very important step, because two thick vascular edges were thus gained, which could be accurately and evenly brought into contact with each other. The second was, the lateral division of the skin and sphincter on each side,—a proceeding preferable, in his opinion, to subcutaneous section, and which contributed greatly to the success of the operation, by preventing all traction on the edges of the wound, and affording great relaxation to the skin and cellular tissue. The third point was, the guarding against the possibility of the urine dribbling on the wound; and the fourth, the tranquillity in which the bowels were maintained for some days after the operation, by the liberal administration of opium. Each of these measures was, he conceived, necessary to the success of the proceeding; and if they were put in practice, and the operation properly performed, he had no doubt that the result would be almost invariably satisfactory."

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

LYKION OF THE ANCIENTS, AND THE MODERN USE OF THE SAME DRUG.

PROFESSOR SIMPSON, of Edinburgh, has collected from various sources some curious and interesting information on this subject, which he has published in the *Monthly Journal of Medical Science* for January 1853. Dr. Simpson describes four ancient Greek vases which have evidently been used by the apothecaries for containing Lykion. He remarks, that "the great rarity of such archaeological remains may serve as some apology for the present notice of some specimens of ancient Greek medical vessels or vases. Besides, the vases which I wish to describe are interesting in other points of view. They are all of them intended to contain one and the same drug, as shewn by the inscriptions on their exterior: this drug was derived by the ancient Greeks chiefly from Hindostan—one of the many points of evidence of the former freedom and frequency of the traffic between the south of Europe and India; and at the present day the same drug is still employed extensively and successfully by the native practitioners of the East, for the very purposes for which it was in former times used by the medical practitioners of Greece. The drug to which I allude, is the Indian LYCIUM, or LYKION, the ATKION INAIKON of Dioscorides. In modern collections and writings, I know of four ancient vases or drug-bottles, intended to contain this valued eye-medicine. If our museums, however, were properly searched, perhaps various other Greek vases for the same or for similar medicines would be detected." Dr. Simpson gives drawings of the four vases, and he learnedly describes their shape and the inscriptions which they bear. Passing over that portion of the essay, we come to the following account of the modern use of the drug in India, and of its recent experimental employment in Edinburgh.

"The Lykion, or Lycium, is still used extensively by the native medical practitioners of India, under the Hindoo name of *Rusot* or *Ruswat*. In a learned article on the nature of the *Aukios* of Dioscorides, contained in the *Transactions of the Linnean Society*, vol. xvii, p. 82, Professor Royle has shown, that the Indian Lycium or Rusot is an inspissated extract, prepared from the wood or roots of several species of Berberis, as the *Berberis lycium*, *aristata*, etc., growing on the mountains and plains of Upper India, and principally procured from Nuggur-kote, near Lahore.* 'On inquiring, says Dr. Royle,

* The other variety of Lycium, described by Dioscorides as procured in Asia Minor (*Lycia*, Cappadocia, etc.), is now generally supposed to be an extract from the *Rhamnus infectoria*, or other species of *Rhamnus*.—See Professor Royle, in *Linnean Transactions*, vol. xvii, p. 87; Dr. Adams, in his admirable edition of *Paulus Aegineta*, vol. iii, p. 234.

'in the shops of the druggists in the bazaars of India, I everywhere learned that both the wood (*dar huld*) and the extract *Rusot* were imported from the hills into the plains, and that large quantities continued to be brought from Nuggur-kote as well as other places.' And he adds, 'the *Rusot* is at the present day procurable in every bazaar in India, and used by the native practitioners, who are fond of applying it both in incipient and chronic inflammation of the eye; and in the latter state both simply and in combination with opium and alum. It is sometimes prescribed by European practitioners; and I have heard that it was found very efficacious by Mr. McDowell in the ophthalmia of soldiers who had returned from the expedition to Egypt. I have myself occasionally prescribed it; and the native mode of application makes it particularly eligible in cases succeeding acute inflammation, where the eye remains much swollen. The extract is by native practitioners, in such cases, rubbed to a proper consistence with a little water, sometimes with the addition of opium and alum, and applied in a thick layer over the swollen eyelids; the addition of a little oil I have found preferable, as preventing the too rapid desiccation. Patients generally express themselves as experiencing considerable relief from the application.'

"My friend, Dr. Wise, the author of that learned work, *Commentaries on the Hindoo System of Medicine*, some time ago brought to Scotland with him a small quantity of the Indian Lykion. I have seen one or two cases of recent conjunctival ophthalmia treated by the application of this Lykion, with speedy relief and cure. Dr. Wise has been so good as to furnish me with the following interesting note regarding his own extended experience with it.

"The use (says Dr. Wise) of the mixture of Lykion or *Rusut* is very generally known over Hindostan, where diseases of the eye are common, and probably over Asia and Africa, if we are to believe that this was the black application employed with such success to the diseased eyes of our soldiers in Egypt. It is likewise probable that Dioscorides obtained it nearly two thousand years ago from the East, where the plant is indigenous, and introduced it into Europe. Having found great personal benefit from the application of the mixture of Lykion to my eyes when inflamed, I employed it extensively when superintendent of the Eye Infirmary, Calcutta; and so convinced was I of its efficacy, that I brought a supply with me to Europe with the intention of bringing it to the notice of the profession. I found you investigating the subject; and at your suggestion, Dr. Walker was so kind as to try the medicine, and I am sure will inform you of the results he saw derived from its use. The Indian mixture consists of equal weights of lykion and burnt alum, with half the weight of opium. These ingredients are mixed with lemon juice, and reduced to the consistence of cream, and applied round the eye-lids and over the eye-brow of the inflamed eyes. This mixture is washed off, and again applied twice in twenty-four hours; and it was only when accompanied with fever, that aperients and other parts of the antiphlogistic regimen were required. In less urgent cases the mixture was only applied at night, and produced no inconvenience, unless when it dried, and the lids felt stiff, when it was softened by applying a little moisture. I found the Lykion mixture most useful in all cases of inflammation of the external tunics of the eye. When both eyes were inflamed, it was interesting to mark the advantage this simple remedy had when applied to one eye, while the usual remedies of leeches, blisters, etc., were applied to the other eye. Another most important application of the Lykion is when the ophthalmia is accompanied with severe pain. On such occasions, after applying the mixture, a piece of live charcoal (*gool*) produced the most soothing effect when approached near the eye. With this intention, the charcoal was placed upon an earthen cup, and held on a wooden stand by the patient, and he approached or withdrew it from the eye according to his own feeling. The great relief in this case was in part from the anodyne effect of the opium.'

"Mr. Walker has kindly given me the following note of his experience with the Lykion at the Edinburgh Eye Dispensary:—

"I have used (he writes me) the Indian Lykion in a considerable number of cases of eye disease. The affections in which I found it most useful were those of the conjunctiva, such as the simple, catarrhal, and pustular forms of inflammation. In them its action was well marked and beneficial, the disease generally subsiding in a day or two; sooner perhaps than it would have done under the ordinary treatment. I have had no opportunity of trying it in purulent ophthalmia; but I believe that in it also it would prove of service. Cases of slight rheumatic and catarrho-rheumatic inflammation have been benefited, but not cured, by it alone. In some affections of the eye-lids, as

ophthalmia tarsi and chronic ophthalmia, it did good; but such cases often get well with very little treatment. I applied it to the eyelids in the form of a paste, with opium and burnt alum, as recommended by Dr. Wise. This was repeated two or three times a-day. The patients generally complained of a burning and smarting of the lids after its application, similar to what is produced by a mustard blister."

We would suggest the necessity of making a comparative trial of a paste of opium and alum made *without* and *with* the Lykion, before any opinion be given as to the value of the latter. We strongly suspect that results equally favourable would be obtained from the paste *without* the Lykion: at all events, we can aver that one of the very best applications in chronic ophthalmia, especially in scrofulous subjects, is a paste or ointment composed of opium, alum, and the nitrous oxide of mercury ointment of the Pharmacopœia, the relative quantity of each ingredient depending upon the specialities of the case. We have not used this application without the mercurial, but very probably that ingredient may in many cases be dispensed with.

RENNET IN DIABETES MELLITUS.

Dr. J. GRAY, of Glasgow, has contributed an interesting paper on this subject to the January number of the *Monthly Journal of Medical Science*. As the value of the remedy can only be fairly estimated by taking into consideration all the circumstances connected with the cases in which it was used, we have not abridged Dr. Gray's article.

"CASE I. John Dryburgh, a married man, 44 years of age, one of the foremen employed at St. Rollox Chemical Works, temperate and regular in his habits, had always enjoyed good health until August 1850, when he observed that his calls to make water were more frequent, and the quantity voided much greater, than usual. The increased discharge was accompanied by great thirst. These symptoms gradually increased, until they became so aggravated that, he says, "had it not been for shame, I could have remained constantly by the well, drinking and making water by turns." His appetite was upon the whole good, every article of diet agreeing with him, except cheese. He was habitually costive, and troubled with uneasy sensations about the epigastric region. He had also experienced numbness in the upper extremities, from the elbows to the tips of the fingers; and in the lower extremities, from the knees to the toes; and he likewise had occasionally a sensation of heat rushing along the arm and forearm to the fingers, continuing about fifteen minutes, and then leaving him feeble, and unable to do anything for some time afterwards. He had lost upwards of three stones in weight; and was very weak, low-spirited, and unable for his usual employment. He had tried various remedies, all of which proved ineffectual in giving him the slightest relief.

"On the 7th of July, the countenance was expressive of great anxiety: he was much emaciated: the pulse was 66, full and regular; the respiration slow; the mouth dry, in consequence of which he was unable to articulate distinctly; the tongue coated with a thick yellowish fur; the appetite good; and the thirst excessive, so that he drank upwards of three gallons of liquids in the course of twenty-four hours. The urine was very abundant, of a bright straw colour, sweet to the taste, loaded with sugar, as indicated both by the sulphate of copper and the caustic potash tests, and in density 1045.

"He was ordered a table-spoonful of creasote mixture, to be taken when the thirst was urgent; and ten grains of the alkaline phosphate of soda, three times a-day, in a glass of water. His diet was made to consist of beef, fish, tea without sugar, eggs, bran-bread, butter-milk, and water. Under this course of treatment, and attending to the state of the skin and bowels,—alternating the creasote with tincture of nuxvomica and tincture of colocynth, he continued for three weeks, with little improvement in the general symptoms; during which period the density of the urine varied from 1045 to 1037.

"On July 30th, he was directed to take a tea-spoonful of rennet in a glassful of water after each meal, and to continue the alkaline phosphate of soda.

"On August 3d, the thirst was not quite so urgent, and he thought he did not pass so much water. He complained of distressing pain in the fore-arms and legs. He did not discontinue the animal diet. The urine was paler in colour, and of density 1027.

"On August 7th, he continued gradually improving, the density of the urine having descended to 1025. As the bowels were confined, he was directed to take ten drops of tincture of colocynth every four hours, until the bowels should be acted on."

"On August 13th, he felt easier about the pit of the stomach; the pains in the arms and legs were not so troublesome; the urine was acid to litmus paper; it contained no albumen, but a superabundance of sulphates, chlorides, and uric acid.

"On August 21st, he felt decidedly better; the thirst had greatly abated; the bowels were regular; the tongue clean; and he slept well. The quantity of food and drink now used in twenty-four hours was 3 lbs. of meat, $\frac{1}{2}$ lb. brown bread, seven cups of tea without sugar, eight ounces of water, and half as much butter-milk. The density of the urine was 1024; and there were only slight traces of sugar. The alkaline phosphate of soda was discontinued; and a few drops of muriatic acid were given along with the rennet.

"He had a smart attack of diarrhoea on the 24th. On the 25th, he gave up taking the rennet. The tongue was slightly coated with a yellowish fur, and the stools were black coloured. He slept well. The quantity of urine passed in twenty-four hours was sixty-four ounces, and its density 1022.5.

"I could not detect the slightest trace of sugar by the caustic potash test. The uric acid was present in lozenge-shaped crystals. Lactic acid was found by Pelouze's test; that is, on boiling the urine with caustic potash, it became turbid, and when allowed to stand a deposit fell to the bottom of the test tube, which, when placed on a slip of glass, partially evaporated, and, examined under the microscope, presented numerous crystals, some of them much resembling a sheaf of corn, and others arborescent. This deposit dissolved on the addition of a solution of prussiate of potash.

"On August 29th, the tongue was clean and moist. He had no longer any thirst, and took no more of fluid than he used to do while in perfect health. He was always ready for food, and was using more farinaceous food. He did not feel any uneasiness from being restricted to the diet prescribed. He had gained six pounds in weight. No rennet had been taken for three days. The density of the urine was 1024. The rennet was resumed.

"On September 2nd, he felt daily stronger, had no thirst, and fewer calls to pass urine; slept well; felt no longer pains in the stomach, fore-arms, and legs; was able to work, and did so with pleasure; and had added three additional pounds to his weight. The urine was 1022, and presented slight traces of sugar.

"On September 8th, he still continued to improve, and gained flesh daily. The density of the urine was 1022; it contained lactic and uric acids; but, when boiled for some time with caustic potash, did not change colour.

"On September 13th, he said his health appeared to himself as good as previously to his illness.

"On November 8th, he felt quite well; had gained about two stones in weight. Since commencing the rennet, the urine had a density of 1018, and no sugar could be discovered in it by any test. He was taking the ordinary mixed diet, and continued the rennet.

"December 24th. This patient continues to enjoy good health.

"CASE II. William Clark, aged 29, ship-carpenter, married, of regular habits, had enjoyed good health until within the last three months, about which time he complained much of thirst, frequent calls to pass urine, general debility, and loss of flesh. These symptoms increased so much towards the close of autumn, as to render him unable for his employment.

"When I was first consulted by him on the 11th of October last, I found the urine to contain a large quantity of sugar, and its density to be 1044. He complained much of pain in the legs and forearms. The tongue was furred; and his articulation indistinct. He had lost a stone and a half in weight. The pulse was 78. There had been no cough.

"He was ordered ten grains of the alkaline phosphate of soda three times a day, in water, and to live as much as possible on an animal diet.

"13th. Density of the urine, 1040. A teaspoonful of rennet to be taken after each meal.

"16th. He felt a little easier, and the thirst was not quite so urgent. The density of the urine was 1034. He was directed to continue the rennet and phosphate of soda.

"21st. He was more cheerful, and returned to work. The specific gravity of the urine was 1035. The phosphate of soda was omitted.

"25th. Within the previous twenty-four hours, he passed 252 ounces of urine, and used 196 ounces of liquids, half a quartern loaf, about two pounds of meat, three eggs, and a boiled cabbage. He perspired occasionally, and was frequently troubled with heartburn. The urine was 1030 in density. He had gained two pounds in weight.

"30th. He felt stronger in the arms and chest, and the pains in the legs were entirely gone; but there still remained

a slight cedematous swelling of the ankle. Urine 1034 in density.

"November 5th. For the last twenty-four hours, he had passed 108 ounces of urine. The thirst was now not nearly so troublesome; the swelling at the ankle was gone; he felt stronger for his work; the tongue was clean; the pulse 76; the appetite good; the urine 1030 in density. He was now directed to discontinue the use of wheaten bread altogether, and, as a substitute, to have bread made with six eggs and four ounces of butter, kneaded into a loaf with common bran, and baked in a slow oven.

"10th. Within the last twelve hours, he had only had three calls to pass urine. He had added four pounds to his weight since he was last weighed. He felt much stronger. The density of the urine was 1030; the sugar was greatly diminished, as shown by the tests; but there was a considerable quantity of lactic acid.

"December 24th. Soon after the last report, I directed him to use chlorine inhalation. I was led to make use of this remedy by the following circumstance. Conversing one day with John Dryburgh, he happened to remark, that, when he had occasion to go into the chlorine-room during his illness when his thirst was urgent, a free flow of saliva took place, which immediately afforded him relief. Under the impression that the chlorine might both act on the sugar circulating in the blood, and also in some way on the nervous system, I was induced to try it in Clark's case.

"For ten days or a fortnight before using it, this man passed urine varying in density from 1030 to 1040. In a fortnight after first using it, the density fell to 1020, and every trace of sugar disappeared. During the last four weeks, the quantity has never exceeded fifty-six ounces in twenty-four hours, and the density has been pretty steady between 1018 and 1020; nor have I ever been able to observe any sugar in it. Every symptom of the disease has now left him; he has regained his former weight; and he feels strong, and as able for his work as ever he was. His diet, however, has not yet been changed; but I have no doubt, judging from John Dryburgh's case, that, by and by, he may with safety return to his usual way of living.

"CASE III. I have now (December 24) a third case under my care who has been ill for eight months. He had been treated in the usual way by several medical men, but without success. At first he made seventeen pounds of urine of the density 1037. Now the quantity is four pounds, and the density 1028. He has used both rennet and chlorine. Before commencing the treatment, his sight was much impaired; but it is now quite restored, and he has almost regained his original weight.

"The issue of this case will be reported afterwards.

"REMARKS. I was led to administer rennet, from knowing the effect which it has upon a solution of sugar. I reasoned thus: If out of the body it converts a solution of sugar into lactic acid, it may have a similar effect upon a solution of sugar within the body; and bearing in mind that lactic acid is found in the juice of flesh, and, according to Liebig, is a supporter of the respiratory process, I considered that, if sugar formed in the body of a diabetic patient could be converted by the rennet into lactic acid, it would be burned in the lungs; and that if a larger quantity were formed than could be consumed in this way, that portion would be excreted by the kidneys. In this I have not been mistaken; for lactic acid was more than once detected in the urine of the first two patients.

"It is necessary that the rennet be recently prepared, and a tea-spoonful capable of coagulating a pint of milk in five minutes; as it not unfrequently happens that, by being kept for some time, it becomes decomposed. Its quality should therefore on all occasions be tested with milk before being used as a medicine."

EXTERNAL USE OF COD-LIVER OIL.

In the *Canada Medical Journal* for May 1852, Dr. A. H. DAVID recommends the use of cod-liver oil, as a local application in various cutaneous diseases. In ringworm of the scalp, he has used it in more than twenty cases, some of which, of an obstinate character, were cured in four or five days. He also applied it in a case of psoriasis inveterata, which had lasted three years. The patient was discharged, cured, in seven weeks.

Dr. ARNOLDI has also used it with good effect in cases of extensive burns, and in frost-bites.

In some cases, it has produced burning heat and intense pain in the parts to which it has been applied; and in one case of acne rosacea, Dr. DAVID was obliged, on this account, to discontinue its use on the fourth day.

ASSOCIATION INTELLIGENCE.

NOTICE TO MEMBERS:—PAYMENT OF SUBSCRIPTIONS.

MEMBERS who have not yet paid their Subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Treasurer (Sir CHARLES HASTINGS), or to the Secretary of the Association, at Worcester.

Gentlemen, joining the Association, are required to observe the 24th rule, which states, that "each member is to pay one guinea annually; and that the subscription commences on the 1st of January in each year, and must be paid in advance."

JAMES P. SHEPPARD, Secretary.

NOTICES BY THE EDITOR.

A LIST OF THE MEMBERS of the Association is preparing for publication. It will include all the new members up to date. Gentlemen who have new members to propose, ought, therefore, to do so without delay.

MEMBERS and others are requested to send books, manuscripts, and letters for the EDITOR, to his residence, Essex House, Putney, London; or to the office of the Journal, 37, Great Queen Street, Lincoln's Inn Fields, London.

Dr. CORMACK will attend at the office, to receive members, every WEDNESDAY, from four to a quarter past five, p.m., when not unavoidably prevented by other duties.

THE COMMERCIAL BUSINESS of the JOURNAL is transacted by the publisher, every lawful day, at the office, between the hours of nine A.M., and seven P.M.; and, to prevent delays or mistakes, it is particularly requested that all advertisements and letters connected with the alteration of addresses, or with the commercial department, be addressed to the publisher, Mr. THOMAS JOHN HONEYMAN, and not to the editor.

EDITOR'S LETTER BOX.

EPIZOOTIC DISEASES.

LETTER FROM THE SECRETARY OF THE EPIDEMIOLOGICAL SOCIETY TO THE EDITOR.*

38, Berners Street, Jan. 8th, 1853.

SIR,—I beg to forward to you the Epizootic queries, emanating from the Epizootic Committee of the Epidemiological Society.

The President and Council of the Society, as well as the members of the Committee, would feel much gratified if any notice of the same should appear in your Journal.

I have the honour to be, sir, your obedient servant,
J. H. TUCKER, Hon. Sec.

1. Has the disease, termed *Pleuro-pneumonia*, existed either among your own cattle, or among any which are under your immediate observation?
2. Has it prevailed in your neighbourhood, and, if so, how near to your own premises?
3. Did the disease *first* appear among the "old stock" of the farm, or among the animals which had been recently purchased?
4. Has it attacked any other variety of animals besides oxen?
5. What is the usual health of the animals kept on the farm, their average age and condition?
6. What number of cattle are kept by you, and how many have been attacked by the disease?
7. Were the breeding or the fattening stock *first* affected?
8. Can its appearance in your locality be traced to any special or direct cause, such as the introduction of diseased animals?
9. To what do you attribute its outbreak in your own herd?
10. Have the cows, either in calf or in milk, been more susceptible to the disease than the oxen?
11. Have you any proofs of calves being affected at birth, or very shortly afterwards?
12. What was the state of the weather at the time of the outbreak; and were the animals, when attacked, exposed to, or protected from, its influence?
13. Is it your opinion that the malady is contagious; and, if so, what proofs have you?

14. How long a time has usually elapsed between exposure to infection and the appearance of the disease?

15. Were the losses quickly replaced by new purchases?

16. Did such newly purchased animals have free communication or not with those that had been previously living with the diseased; and, if so, for what period of time?

17. Have these new animals been equally the subjects of disease?

18. Is the malady on the increase or otherwise?

19. What are the symptoms marking the commencement of the attack, and are they easily recognized or not?

20. What are the symptoms which accompany the progress of the disease, and particularly those that indicate the greatest danger?

21. Have any animals recovered in whom diarrhoea has shown itself in an advanced stage of the malady?

22. What number of the cattle have died, and what proportion has been killed, or otherwise disposed of?

23. What are the usual *post mortem* appearances? is effusion of serous fluid into the chest usually present?

24. In how many cases were both lungs diseased? in how many was the right lung alone affected? and in how many the left alone?

25. In what state or condition has the disease left those animals that have recovered from mild or severe attacks?

26. Has it seemed to have any effect in producing abortion?

27. Do you know of any instances in which an animal has become a second time attacked with a mitigated form or otherwise of the disease?

28. What are the causes which you have found to be the chief obstacles to the eradication of the malady?

29. How long is it since the first case occurred in your herd, and how long since the last case?

30. Has the disease steadily progressed, or have there been repeated outbreaks after intervals of freedom from disease?

31. Has prevention been attempted by change of diet, situation, or management; by medical treatment, or any other means?

32. What results have followed the adoption of the preventives employed?

33. Is the general character of the district in which you reside flat or hilly, dry or damp, wooded or open?

34. Are the pasture grounds free from stagnant waters and bogs, and is land drainage generally adopted?

35. Is irrigation of the pasture grounds carried out to any extent?

36. Are the cattle sheds well drained and ventilated?

37. Is the system of "box feeding" adopted either upon accumulating manure, or upon boarded floors placed over pits for the reception of the dung and urine?

38. Did any blight, mildew, or similar affection manifest itself amongst your corn, or other crops, previous to or about the time that your cattle became diseased?

39. Have any epidemic diseases prevailed among the people in your locality, either shortly before, or during the appearance of the malady in question?

40. Does any other epizootic affection besides the one which forms the special subject of this inquiry exist among domesticated animals in your district? and if so, state,—

I. What animals are affected.

II. The leading characters of the disease.

III. The per centage of death it produces.

P.S. The following gentlemen compose the Epizootic Committee of the Epidemiological Society:—

CHAIRMAN, Professor J. B. Simonds, Royal Veterinary College.
HON. SECRETARY, *pro tem*, E. N. Gabriel, Esq., Rolls Buildings, Fetter Lane. MEMBERS: B. G. Babington, M.D., F.R.S.; M. Martin de Bartolome, M.D.; B. Cartledge, Esq., V.S.; Robert Ceely, Esq., M.R.C.S.Eng.; T. B. Davis, Esq., F.R.C.S.; Thomas Foster, Esq., M.R.C.S.; Robert Garner, Esq., F.L.S., M.R.C.S.; W. T. Karkeek, Esq., V.S.; W. Litt, Esq., V.S.; J. F. Marson, Esq., M.R.C.S.; T. W. Mayer, Esq., V.S.; W. Robinson, Esq., V.S.; F. Sibson, M.D., F.R.S.; John Snow, M.D.; W. C. Spooner, Esq., V.S.; S. Mayer Turner, Esq., M.R.C.S.; T. Wells, Esq., V.S.; J. Wilkinson, Esq., V.S.

HOMŒOPATHY IN EDINBURGH.

LETTER FROM WILLIAM OGLE, Esq., TO THE EDITOR.

St. Catharine's Hall, Cambridge, Jan. 23, 1853.

SIR,—As a member of the Royal Medical Society of Edinburgh, and of the Association, I have pleasure in transmitting the

* Vid: p. 28 of last number.

statement which appeared in the Journal of the 14th inst., that "the Royal Medical Society lately refused to place on their library shelves a presentation copy of a work by a homœopathist". I may add, in reference to the University of Edinburgh, at which I was a student from Nov. 1850 to Nov. 1852, that the heresy of homœopathy is fully exposed by more than one professor in his annual course of lectures. I have notes of two lectures by Professor Christison on the subject.

Once more, Professor Henderson is watched; and (as I have understood, for I did not attend his course) no one has yet been able to detect a homœopathic tendency in his teaching. If your correspondent, "Pater", is in fear of any of his friends, let him not, without some better cause than the one assigned, dissuade them from resorting to the Medical School of Edinburgh. A more certain antidote, and more pleasant, surely will be to urge them to attention to the sound teaching of the professors; and to join without delay the young aspirants to fame in their weekly meetings at the Hall of the Royal Medical Society.

Your obedient servant, WILLIAM OGLE.

MONTHLY REPORTS OF THE BENEVOLENT FUND.

LETTER FROM DR. GRIGOR TO THE EDITOR.

SIR,—I was greatly interested by the editorial article on the Benevolent Fund, which you describe as an "integral part of the Association"; but as a new member, I am inclined to beg for more information. Would it not be useful to report monthly the operations of the Benevolent Fund Committee? I would also suggest, that the subscriptions and donations should be occasionally advertised in your columns, so that we might be able to show the list when a favourable opportunity occurred for obtaining subscriptions to a cause, which the public as well as the profession ought to support. I am, sir, your obedient servant,

JOHN GRIGOR, M.D.

Nairn, N.B., 15 Jan. 1858.

[Suggestions very similar to those contained in Dr. Grigor's note have reached the Committee from different quarters, and they are anxious to cooperate with us in carrying them out.]

NEWS AND TOPICS OF THE DAY.

ACCIDENTAL POISONING BY FLEMING'S TINCTURE OF ACONITE, AT THE CONVENT OF THE GOOD SHEPHERD, NEAR BRISTOL: CORONER'S INQUEST.

On Saturday, the 16th inst., Mr. B. Fry, the coroner for the northern division of the county of Somerset, concluded, at the White Hart Inn, Brislington, near Bristol, an investigation touching the death of Emma Forty, an inmate of the Roman Catholic Convent of the Good Shepherd, situated at Arno's Vale. Deceased, it appears, had had administered to her, by mistake, by the sister-attendant, Miss Sophia Ryder, a poisonous dose of aconite, instead of the medicine prescribed for her, and which resulted in her death in about five hours.

This being a reformatory institution, the inmates, on entering, have a fresh name given them, so that, if possible, their real names may not be known to each other. The penitents will therefore be found distinguished in the sequel as Celeste Wilton, otherwise Veronica, etc., the former being the real, the latter the assumed name.

CELESTE WILTON, otherwise Veronica, deposed that the deceased, Emma Forty, otherwise Melanie, came into the infirmary on Monday morning last, at a quarter past 7 o'clock, complaining of sickness, and stating that she had vomited a great deal. Witness administered some salt and water, to bring off the bile, from which she conceived the deceased to be suffering. When asked where her pain was, deceased did not speak, but put her hand to the lower part of the chest. She was alive but motionless when witness left her.

MARY HUTCHINSON, otherwise Aloysius, took up the dinner of the deceased, when she found her dead.

MARY POWER, otherwise Sister Mary of Stanislaus, stated that the deceased was taken ill in the chapel on Monday morning, and was conducted by her to the infirmary. At 9 o'clock witness went to the infirmary accidentally; the deceased appeared ill, but witness thought she would get better by and by. It would not have been her duty to send for a medical man. She left that for the Superioress.

SOPHIA RYDER, the sister-assistant who administered the poison, having been sworn, deposed that the deceased was under medical treatment for tape-worms. Dr. O'Brien ordered for her a solution of pomegranate one drachm, and one grain of quinine, to be taken fasting. She said:—I had made a solution of the pomegranate and put it into a bottle. I am in the habit of dispensing the prescriptions of Dr. O'Brien. We have a large medicine cupboard in a room which is called the *economat*. Any of the sisters might go into the room, but no one would have permission to administer medicine except myself and a sister appointed to assist me. None of the penitents have access to that room. On Monday last, at the usual time, shortly before 7 in the morning, I was to have given to Melanie (the deceased) a dose of the medicine ordered for her by Dr. O'Brien. I went into the *economat* for the purpose of preparing the medicine. I took a bottle off the shelf; I poured a drachm of it, which is about one teaspoonful, into a cup. I put also into it one grain of quinine, and poured water, about a wineglassful, into it. I took the cup into the class-room, and administered it to the deceased. The deceased left the room and went down into the chapel. Five minutes after she asked my permission to leave the chapel to get some water, and left with me. I gave her a cup, and she drank about half a pint. She returned alone to the chapel. About a quarter-past 8, I next saw her in the infirmary. She appeared in pain, and was very sick. Veronica, who was holding her, said, "Mother, I think she is very bilious," and I said, "What shall we give her?" Veronica replied that a little salt and water would do her good. I left the infirmary, and returned about 9 o'clock. She was still sick, and appeared to be in great pain, throwing herself about. I did not feel it necessary to send for a medical man. I went again to the deceased about 10 o'clock. She was then quiet, and lying down. I asked Alphonsine how she was. She said "she has gone to sleep, mother. I think she will be better soon." She did not then appear in pain.

The large bottles in the medicine-cupboard were labelled by the druggist, but the bottle from which I administered this medicine was not labelled. I had given one dose on the Saturday to the deceased from a saucepan on the fire, in which I had made it on the Friday night previous. I poured the remainder of the decoction into a bottle in the cupboard, which was locked up. On Monday morning, when I was about to administer the medicine to the deceased, I took a bottle from the shelf, supposing it to be the bottle in which I had put the decoction of pomegranates. Neither of the bottles was labelled. I took the one from the shelf in which I had been in the habit of placing the dispensing medicines. I did not discover my mistake till many hours after.

I had in my possession a bottle containing aconite and morphine, which I had mixed on the Friday previous as an external application for toothache. I had applied the embrocation with linen to the face of Veronica. She complained that it gave her so much pain she would not have it on again. I knew when I made this mixture that aconite was poisonous. I forgot to label the bottle. The deceased did not say to me I had by mistake given her poison instead of medicine.

The SUPERIORESS deposed to having seen the deceased on Monday last. She was vomiting or retching. She did not consider it necessary to send for a medical man. The sister-assistant afterwards came and said, "a dreadful thought has flashed across my mind, that I have taken the wrong bottle." When Dr. O'Brien arrived, the sister-assistant seemed in a distressed state, and brought the bottle to Dr. O'Brien, and said, "I think I have given the embrocation by mistake." Dr. O'Brien, after tasting the contents of the bottle, confirmed that opinion.

DR. O'BRIEN stated that he had been called in, and satisfied himself that a portion of the contents of a bottle, containing a tincture called "Fleming's Tincture of Aconite," had been administered. He attended the deceased on the 6th inst. for tape-worm, and had ordered her a drachm of the bark of the root of pomegranate and a grain of quinine in water every morning fasting. He diligently inquired into the symptoms that followed upon the administration of the aconite, and they exactly corresponded with those that are known to follow a large dose of that drug, a drop or two being the ordinary internal dose; even that was sometimes followed by specific effects. The deceased died from the aconite.

The inquiry was then adjourned to the following Saturday in order that a *postmortem* examination might be made, which the jury deemed to be absolutely necessary.

DAVID GRANT M'PHERSON, surgeon, stated that he had been called in as the nearest medical man on Monday the 10th. Before the new-Superioress came, he was the medical attendant

at the convent. Asked the Superioress to what cause she attributed the death? She replied that she did not know, but two or three of the family had died sudden deaths. Asked her if the deceased had struggled much before death, and was told she had thrown herself about a good deal, saying she felt the worm in her stomach. Had known several patients who had tape-worm complain of great pain. When he attended the penitents they often complained of pain; he could find no cause for it, and therefore did not make much account of it. He told the Superioress that deceased seemed to have died from an irritant poison, such as copper. Miss Ryder showed him a few drops of a dark-coloured fluid, saying that was the remains of the medicine she had administered. He was surprised at seeing it so dark, and tasted it, and the whole of the afternoon and evening his tongue and lips were tingling from the effects of the medicine, and he was made quite ill. To the best of his knowledge, none of the inmates expressed to him their opinion that the deceased had been poisoned. When he was medical attendant, he always dispensed medicines of a dangerous character himself.

Dr. O'BRIEN deposed that he had assisted in making a *post mortem* examination of the body. The brain was healthy, so were the lungs and heart. The stomach contained a little fluid, and its membrane presented diffused marks of congestion over the large curvature. The *duodenum* presented appearances of very active inflammation of its lining membrane, which was softened and in patches dissolved. Some spots were so dark, that if life had endured sufficiently long they would have ended in mortification, the inflammation was so great. In the small intestine he found a very large tape-worm, dead. The *sphincter ani*—a very unusual occurrence—was relaxed. He never dispensed medicine at the convent, he only wrote prescriptions, even if the drugs were dangerous. He never ordered internally any dangerous medicine in that house. Messrs. Ferris and Score supplied the drugs to the convent. The bottle sent by Messrs. Ferris and Score containing aconite had not the word "poison" written or printed on it, and only the words "Fleming's Tincture of Aconite." He went to inquire the reason why the word "poison" was not put on a medicine so dangerous as that; and they replied that they understood the medicines would be dispensed by a medical man. I had a conversation with Miss Ryder, and she said it would have been a great assistance if that word had been upon it. When I found it necessary to prescribe the tincture of aconite for neuralgia I entered such prescription in a book, and wrote "for external use"; and, in addition, I made Miss Ryder, as I thought, perfectly acquainted with the power of the drug, and the manner and quantity in which it was to be used.

Dr. AUGUSTIN PRICHARD, one of the surgeons of the Bristol Infirmary, and lecturer on anatomy at the Bristol Medical School, who had assisted at the *post mortem* examination, corroborated the evidence given by Dr. O'Brien as to the appearance of the body. He had no doubt that death was produced by an irritant poison, first acting upon the stomach and intestines, and then on the nervous system. A teaspoonful of the tincture of aconite in a glass of water would be sufficient to produce the appearances described, and to cause death. He was not aware of any chemical tests by which tincture of aconite could be ascertained in such a mixture as was contained in the stomach. He examined the surface of the stomach, to see if there were any traces of metallic poison, and found none.

SOPHIA RYDER was recalled, and said that the deceased was treated kindly in the establishment. There was not a penitent in the house but loved her,—she was such a sweet child. Deceased had never been corrected for any misconduct, and, as far as witness knew, had never expressed a wish to leave the establishment. As far as she knew, deceased came to the establishment of her own free will.

The CORONER could not conclude this examination without giving the witness a caution never again to place herself in such a painful position. He implored her never again to administer dangerous medicines of which she had no knowledge.

The SUPERIORESS having been called, the CORONER said that she ought not to permit any one in her establishment to administer medicines of so dangerous a character. It was necessary that they should have a medical man to administer all medicines. Here was a poor young woman deprived of life through carelessness. He did not wish to wound her feelings, but it was his duty to caution her, and he hoped that this might act as a warning on all future occasions, to her and others.

The jury returned the following verdict:—"That the death of Emma Forty was occasioned by the administration of aconite, a poisonous drug, given to her by Miss Ryder in mistake for

medicines prescribed for her. The jury wish also to express their opinion that much blame is attributable to the authorities of the convent, for allowing a practice which prevails of permitting persons to dispense medicines who, from the want of the necessary education, are ignorant of their nature. The jury further express a hope that in future such practices will be discontinued."—The jury also concurred in the cautions and censures of the coroner.

Mr. GILLON, a medical gentleman connected with the establishment, undertook that the present practice should be discontinued in this convent.

[We have abridged from the *Times*, of Monday last, this melancholy case, because it is one well calculated to call attention to the great risks which are constantly being run, not only in convents and schools but by the public at large, from two very easily remediable causes:—viz., the dispensing of poisonous drugs by ignorant persons, and the unnecessary strength of many of our tinctures and other medicinal preparations. A less potent tincture of aconite ought for safety and convenience to be substituted for those now in use.]

A SURGEON COMMITTED FOR MANSLAUGHTER. A very painful sensation has been created in Bedford, by the committal, under the following circumstances, of Mr. Robert Hicks, the highly respected surgeon of Toddington. It appeared, that as Mr. Hicks was passing the house of a Mr. Ward, he was called in, and requested by Mrs. Ward to examine her son's leg, which she suspected had been severely injured by a fall. After examining the leg, Mr. Hicks said that the small bone was broken, and applied to it a diachylon plaster, bandaging the limbs—the mother having told him he could not set it that night. The child, who was four years old, was brought to him the following morning, when he substituted pasteboard for the plaster. The child getting worse the next day, Mr. Hicks, jun., attended, and expressed a fear that a gathering was taking place under the knee; whereupon he and his father consulted, and applied a bread poultice to the whole limb. That evening Mr. Benson, surgeon, was sent for, but he could do nothing for deceased, who died that night. Mr. Benson, before the coroner's jury, stated, that he performed the autopsy, and found no fracture of the leg, but that under the knee joint, some matter, which filtrated through the muscles of the leg, had escaped. In his opinion, death resulted from congestion of the brain, produced by the pressure of the bandage. Mr. Hicks' treatment was injudicious. Mr. Thompson, surgeon, corroborated Mr. Benson. It further appeared, that Mr. Hicks gave a certificate of death, stating that deceased died from an inflammation of the bowels and knee-joint. The jury returned a verdict of "Manslaughter" against Mr. Robert Hicks, who was accordingly committed to jail, under the coroner's warrant.

[The above probably contains many inaccuracies; but there can be no mistake as to the absurdity and injustice of the verdict.]

A CORONER BROUGHT TO HIS SENSES. At the sessions of Longford, for December, 1852, Dr. Nicolls obtained a decree against one of the coroners of said county for 2*l.* 2*s.*, a *post mortem* fee, which sum the grand jury had disallowed, the barrister, Thomas O'Hagan, Esq., Q.C., holding that the 30th section of the coroner's act made it obligatory on the grand jury to present such sum as would reimburse the coroner.

"Well done, Dr. Nicolls!" exclaims the *Dublin Med. Press*, "if every one acted in this way, we should have less to complain of."

REDUCING THE SALARIES OF POOR LAW MEDICAL OFFICERS. A parliamentary paper has just been printed respecting the Tewkesbury Union. The board of guardians carried resolutions to reduce the salaries of the medical officers, on account of the "cheapness of provisions." The officers appealed to the Poor Law Board, and the reasons were required from the guardians that induced them to pass the resolutions. They urged that the value of agricultural produce had been diminished at least 30 per cent., that the rates had decreased, and that food was cheap. The Poor Law Board replied, that they had "never recognized the principle that the price of the articles and of the produce referred to are to be the criterion by which the amount of salaries ought to be estimated and regulated, or that such salaries should be liable to vary as the price of food fluctuates." The Poor Law Board thought that no sufficient reason had been assigned for the reduction, declaring that the fixed salaries of the medical officers remunerated them only for their ordinary duties, and the board did not see that sufficient grounds had been adduced for diminishing the salaries of the officers referred to in the resolutions of the guardians.

PATHOLOGICAL SOCIETY OF LONDON. At the Annual Meeting of the Society, recently held, it appeared that thirty-five new members had joined the Society, while ten names had been removed from the list on account of death or resignation. The following gentlemen were elected officers for 1853. **PRESIDENTS:** B. G. Babington, M.D., F.R.S. **VICE-PRESIDENTS:** P. M. Latham, M.D.; James Copland, M.D., F.R.S.; Thomas B. Peacock, M.D.; H. Bence Jones, M.D., F.R.S.; Caesar Hawkins, Esq.; John Avery, Esq.; William Fergusson, Esq., F.R.S.; Edward Stanley, Esq., F.R.S. **TREASURER:** Alexander Shaw, Esq. **COUNCIL:** John Hall Davis, M.D.; C. J. B. Williams, M.D., F.R.S.; Edward Bentley, M.D.; W. Jenner, M.D.; Henry Fuller, M.D.; W. Brinton, M.D.; Charles John Hare, M.D.; C. Handfield Jones, M.D.; Joseph Ridge, M.D.; T. Ogier Ward, M.D.; Mitchell Henry, Esq.; Edwin Canton, Esq.; James Dixon, Esq.; John Gay, Esq.; W. Coulson, Esq.; Barnard Holt, Esq.; Charles Brooke, Esq., F.R.S.; William Adams, Esq.; Robert Woollaston, Esq.; Carsten Holthouse, Esq. **HONORARY SECRETARIES:** Richard Quain, M.D.; George Pollock, Esq.

MEDICAL BENEVOLENT COLLEGE. The building operations are now going on in the neighbourhood of Epsom. On the 1st of December last, the Council formally took possession of the land on which the College is to be built. The site is about a mile to the south-east of the town of Epsom, on an elevated position, and commanding a beautiful view of the surrounding country. The soil is dry, with a substratum of chalk, but there will be no difficulty in procuring a plentiful supply of good water. The placing the first stake in the ground by J. W. Freshfield, Esq., M.P., was followed by a prayer by the Rev. George Pocock, one of the Council. The College is intended, first, to furnish an Asylum for 100 legally qualified medical men, or their widows, who have at least 15l. a-year each; secondly, to furnish a superior education to the sons of medical men, at 25l. a-year each, or about one-half the usual cost. Many orphans will be entered as Foundation Scholars, and educated and maintained entirely at the expense of the Society. The first outlay is estimated at 20,000l., and the yearly expenses at 2,000l.: 12,000l. has been subscribed.

After taking possession of the land, the party proceeded to the Spread Eagle Inn, where about eighty, including the leading tradesmen in Epsom, sat down to a splendid dinner.

J. W. Freshfield, Esq., was in the chair, and John Probert, Esq., 6, New Cavendish Street (the founder of the Institution), vice-chairman. Amongst the company were the Rev. G. Pocock, Dr. John Conolly, Dr. Sieveking, Dr. Gibson, Dr. Goodfellow, Dr. Tukey, Dr. Price, Dr. Power, Dr. Sempile, and H. Pownall, N. Clifton, G. T. Dale, W. Self, John Lewis, R. D. Edgcombe, John Chippendale, S. Roots, G. Pilcher, T. Hunt, W. Carr, C. F. J. Lord, W. C. Meates, Robert Dunn, John Ince, George Curtiss, J. F. France, P. Martin, W. Hart, W. T. Iliff, John Harris, E. Clifton, T. J. Ryder, G. W. Driver, H. T. Davies, F. Crew, T. J. Clarke, Esqrs.

The festival concluded at about ten o'clock, and the majority of the company returned to town by a special train, highly delighted by the proceedings of the day.

NUMBER OF MEDICAL STUDENTS INCREASING. Commercial prosperity, cheap food, and emigration to the gold-fields of California, have lately, both in France and England, enabled an unusual proportion of parents to give a liberal education to their children. The consequence has been a great influx of recruits into the professions, and particularly into the too crowded ranks of medicine, which, however, does not at once suffer by this unneeded accession, as many who were struggling for existence as medical practitioners have abandoned the weary contest and followed the multitude to the diggings, thereby in the mean time slightly relieving those left behind from the evils of undue competition. It is not easy to ascertain the number of students at the different schools in London; but as far as we can learn, it is greater now than for some years past. At Edinburgh, pupils are also more abundant. The *Edinburgh Monthly Journal* of December says:—"It is once more our pleasing duty to record an increase in the number of medical students attending classes in the Edinburgh University. The numbers of the matriculated on first December, 1852, were 497, being an excess of 73 over 1851." We are afraid that the statement conveyed in the sentence which follows the above is not correct, and that the exodus to the diggings, in place of diverting students from metropolitan or other schools, is at this moment powerfully contributing to fill their benches. "We may add," says our contemporary, "that for some years past, the increase has been progressive, and that too in spite of the allurements of the 'diggings'—which are said to have diverted no small number of students from the benches of the metropolitan schools." We sincerely regret that we cannot congratulate our brother prac-

tioners upon any such hope of relief, as is here indicated. It is in Paris, however, that the present influx into the medical profession is most remarkable, as will appear by glancing at the subjoined statement of the number of inscriptions at the Faculty of Medicine during the last twelve years:—

YEARS.	INSCRIPTIONS.	YEARS.	INSCRIPTIONS.
1840	879	1847	859
1841	749	1848	784
1842	791	1849	880
1843	746	1850	1,223
1844	800	1851	1,300
1845	851	1852	1,437
1846	903		

The extraordinary increase during the later years, especially during 1852, may not perhaps entirely depend upon real abundance of capital, but partly upon the artificial means adopted during recent political changes to create an easy system of credit, and a free circulation of money among the speculative classes. However the facts may be explained, they deserve to be recorded, and considered with the light of future years.

MEDICAL STATISTICS OF FRANCE. The *Gazette des Hôpitaux* states that in France there are 11,217 physicians, 7,221 *officiers de santé*, and 5,175 *pharmaciens*. These numbers give one medical attendant for every 1,940, and one *pharmacien* for every 6,914 of the population. What is singular is, that the richer departments have fewer doctors than the poorer; thus in those of the north there is one practitioner for every 2,490 persons, while in the south there is one for every 1,619. It is still more singular, that there are nearly 600 towns or communes, with populations varying from 2,000 to 8,000 souls, which have neither medical practitioner nor *pharmacien*.

The commission appointed to examine into the state of the lodgings occupied by the poorer classes in Paris has just published a report. The investigations of the commission have embraced three categories of habitations; the lodges of porters, private houses and lodgings, and furnished lodgings. Among the first category, there are many which are really infectious holes. Their insalubrity arises from various causes: from the dampness of the walls, and from want of space, air, and light. The commission has been able to remedy many of them by enlarging the lodge and opening windows; but in many cases all improvement has been found impossible, and the commission has required from the owners that no one should be allowed to sleep in them. In the second category—private houses and lodgings—the commission found the same causes of insalubrity, and ordered similar measures for rendering them more healthy. As to the external causes which still more increased the insalubrity of different houses, such as piles of rubbish, stagnation of water in courts and alleys, want of proper drainage, exhalations from cesspools and waterclosets, and the bad state of the staircases and passages, the commission has found no difficulty in removing them, as an application to the owners has been almost always promptly attended to. The furnished lodging-houses have excited the particular attention of the commission. The commission caused the most urgent measures to be adopted, such as ordering the number of beds in each room to be diminished, and prescribing the observance of more cleanliness. The number of private houses visited by the commission amounted to 100, of which 42 have been pronounced to be in a healthy state, and 58 have had improvements made to render them so.

The quarters St. Jacques, Jardin des Plantes, and St. Marcel contain many narrow streets, into which the rays of the sun never enter, and which, being built on a steep, receive the infiltration from the ground above them. These quarters remain just as they were in the middle ages; and their unfavourable situation, which is rendered more unhealthy by the careless habits of the inhabitants, is such that only the most general measures can be adopted. It is to remedy this state of things that the city has decided on opening the new street called the rue des Ecoles, which will tend to admit more air into this part.

BATHS AND WASH-HOUSES FOR THE POOR OF PARIS. The following paragraph appeared in the *Moniteur* of the 17th December:—"The Emperor has just decided upon establishing, in three of the poorest districts of Paris, three model institutions for public baths and wash-houses. The expenses of these establishments are to be defrayed from the private purse of his Imperial Majesty." *L'Union Médicale*, in quoting the above, remarks that mere sanitary advice does very little good; and that hygienic measures can only be brought into operation by being imposed upon the people by example and by law. Our contemporary adds—"Conseiller est bien, agir vaut mieux encore, et l'Empereur agit."

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION. From the *Athenæum* of Jan. 15th:—"A meeting of the London Members of the Provincial Medical and Surgical Association was held last Tuesday, at the Hanover Square Rooms, for the purpose of constituting a Metropolitan Counties Branch. This Association—which was first formed with a view to bringing together provincial medical practitioners, and in some measure counteracting the exclusive London interest of the great medical corporations—has succeeded in a remarkable manner, and presents a powerful organization for carrying out measures of interest to the medical profession. Its success has tempted it to storm the capital itself. Already it supports a Medical Journal, published in London; and from the hearty co-operation which it experiences on the part of a large body of London medical men, we should think this Association bids fair to become the representative of the medical profession throughout the British Empire. Such a union has been greatly wanted, and would promote those legislative measures which are so much needed to place the medical profession in this country in a position suitable to the demands and requirements of the age."

MEDICAL BENEVOLENT COLLEGE. We have great pleasure in announcing, that the Lord Bishop of Oxford has kindly fixed the 8th of May next for advocating the claims of this national undertaking, in St. Peter's Chapel, Vere Street; the Rev. EDWARD SCOBELL, the incumbent, having granted the use of his pulpit for that occasion. In addition to the land recently purchased by the Council at Epsom, a piece adjoining has handsomely been presented to the College by JAMES GADESSEN, Esq., of Ewell Castle; as well as a donation to the funds of £25.

ST. GEORGE'S HOSPITAL. Mr. CESAR HAWKINS, the President of the Royal College of Surgeons, has just presented to the Pathological Museum of this hospital a collection of nearly 600 preparations, illustrative of some of the rarest forms of disease that come under the notice of the surgeon. The collection is increased in value by the addition of a descriptive catalogue.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were members of the Association.]

- AGAR, Staff Assistant-Surgeon Rowland, at Tangalle, Ceylon, on 28th October, after a long illness from fever.
 DRANE, Assistant-Surgeon Henry, of the Bombay Army, at Bombay, on November 8th.
 *FOSTER, Thomas Wood, Esq., M.R.C.S.Eng., Surgeon to Wortley Union, at Ecclesfield, Yorkshire, on 18th Dec. 1852, in consequence of a fall from his horse.
 GRAY, Surgeon Peter, at Bombay, on November 10th.
 LESLIE, Patrick, M.D., of 27, Wilton Place, Belgrave Square, London, at Folkestone, on 31st Dec. 1852, aged 62. Dr. Leslie was 18 years in the medical department of the H.E.I.C. Service, Bombay.
 *MARTIN, William, Esq., House Surgeon to the County Hospital at Winchester, lately.

APPOINTMENTS.

[*An asterisk is prefixed to the names of members of the Association.]

- *BAIRD, A. W., M.D. (late of Ipswich), was elected, on the 4th inst., one of the Physicians of the Dover Hospital and Dispensary.
 *BARRETT, John, Esq., F.R.C.S., elected Surgeon to the Western Dispensary, Bath.
 FOOTE, R. F., M.D., appointed Resident Physician to the Norfolk County Lunatic Asylum.
 WADHAM, —, M.D., elected, on 23rd December, Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, at Brompton.
 *WAKE, Robert, M.D., of Southwold, Suffolk, one of the Council of the Provincial Medical and Surgical Association, has received by Royal Letters Patent, the appointment of High Steward of the Borough, Town, Manor, and Lordship of Southwold. Dr. Wake has exercised magisterial functions as a J. P. for many years. He has lately retired from practice, after having been actively engaged for thirty years in the exercise of his profession.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. IV.

LONDON: FRIDAY EVENING, JANUARY 28, 1853.

NEW SERIES.

ARE THE MEDICAL CHAIRS IN THE SCOTTISH UNIVERSITIES TO BE RESERVED FOR MEMBERS OF THE ESTABLISHED CHURCH OF SCOTLAND?

A MAJORITY of the clergy of the Established Church of Scotland have not only boldly answered this question in the affirmative, in Presbyteries, Synods, and General Assemblies, but have been for some time past, and are at the present moment, strenuously endeavouring to obtain for their communion this extraordinary monopoly; a monopoly which, if allowed to be created, would dangerously cripple the Scottish Universities, and ultimately destroy them as medical schools.

Fortunately, but few of the lay adherents of the Established Church of Scotland have become infected with the intolerance which has reappeared among their clergy; and we rejoice to find the tolerant lay party of that communion headed by some of the most eminent members of the medical profession, and—what is more important as regards the issue of the struggle—represented in the upper House of Parliament, and in the Cabinet Council of Her Majesty, by a Scottish nobleman, generally recognized as one of the most rising and most honest statesmen of the day. As might be expected, the liberal and patriotic speech of his Grace the Duke of Argyll, recently delivered in the House of Lords, upon the Religious Tests in the Scottish Universities, has excited alarm among the narrow-minded clerical faction to which we have referred. A notable manifestation of this dismay lies before us in the form of a pamphlet, by "The Rev. Adam Duncan Tait, minister of Kirkliston." It is entitled a "*Letter to his Grace the Duke of Argyll on the proposed abolition or modification of the Tests affecting the Chairs in the Universities of Scotland.*"* The production is a prosy and rapid sermon upon a misapplied text printed upon the title-page, viz.: "Remove not the ancient landmark which thy fathers have set." (Prov. xxii, 28.)

Mr. Tait's letter has no claims upon our attention, except the circumstance that it speaks the sentiments of that majority of the Scottish established clergy, who wish to resuscitate an old and obsolete enactment, passed by the Scottish parliament in troublous times, when the respective partisans of Presbytery and Prelacy were ranged against each other in fierce and unrelenting antagonism. Long ere the recent disruption in the Church of Scotland, time had smoothed down these unhappy animosities; and the secular chairs had been *de facto*, though not *de jure*, thrown open to men of learning and of genius, even though adherents of that very episcopacy against which the Test barrier was first erected. At the moment when we write, a majority of the secular chairs in the University of Edinburgh are filled by episcopalians, and other dissenters from the established church; and, as

the Lord Advocate (James Moncrieff)* stated in the House of Commons, upon the 27th of April last:—

"The truth is, that the Scottish Universities are happily for ourselves *absolutely studded with episcopalians*—to the great scandal of the law, no doubt, but to the great benefit and gratification of the country. If," (he continues) "the Crown were now to purge out heretical professors, our (Scottish) Universities would be deprived of their brightest ornaments. Sir David Brewster would be dethroned from his principality of St. Andrews; Forbes and Kelland would be lost to science and Edinburgh; Ayton to literature; such men as Simpson and Miller to the Medical School; in short, not to detain the House with details, out of about eighty professors in the Scottish Universities, twenty-four, or more than a fourth, are admitted contrary to law. In Edinburgh, the Test is almost in desuetude; in Glasgow and the other Universities it is taken as a form. I know not which is to be the more lamented—that a law should stand on the Statute-book and be perpetually contemned, or that the Test should be taken by honourable men, a pledge binding them to submission to a church they disown, a vow on paper which is powerless on their consciences."

In addition to the eminent professors above named by the Lord Advocate, (and whom the reverend pamphleteer and his friends would exclude from the Scottish Universities), are at least two members of our ASSOCIATION,—men who are bright ornaments of their University, and champions of the departments of science which they represent. We mean Mr. Syme, professor of Clinical Surgery, and Dr. Balfour, professor of Botany in the University of Edinburgh. Both of these gentlemen are, we believe, episcopalians.

Upon a future occasion, we intend to glance at the history of the Scottish Universities, and to point out the position which they occupy in relation to the Established Church. In the mean time, we would draw particular attention to the fact, that the Test was originally devised by the friends of the "Covenant" who gained the ascendancy at the close of the seventeenth century, when prelacy was abolished as an "unsupportable grievance to the nation." In 1690, an act was passed by the Scottish parliament, which provided that none should be admitted as professors "who shall not subscribe the Confession of Faith, swear and subscribe the Oath of Allegiance, and submit to the government of the Church now settled by law." The act thus obtained in these excited times, was intended to exclude *episcopalians* from the University chairs; but the modern intolerants wish, it cannot be concealed, to resuscitate this obsolete enactment, less for the purpose of excluding *Prelatists*, than *sturdy Presbyterians*,—men, who hold and preach the very same doctrines which they hold and preach, who adhere to the same form of Church government, and who actually have, as their theological standard, the same Calvinistic Confession of Faith,—men, who claim to be considered as

* Bro., pp. 56. Paton and Ritchie, Edinburgh, 1853.

* Mr. Moncrieff, the present Lord Advocate, is a Member of the Free Church, and is generally returned as a "lay elder" to its supreme court, or "General Assembly"; which sits annually in Edinburgh, and is composed of clerical and lay representatives from the different Presbyteries.

the true representatives of the Covenanters,—men, who in fine (rightly or wrongly, we say not), in 1842 relinquished their state pay from conscientious scruples, and, as they conceived, “to preserve the ancient landmark which their forefathers had set”; and who, thereby, *without any change of creed*, became unable to “submit to the government of the Church now settled by law”. The new zeal which has sprung up among the Scottish established clergy, in favour of securing “godly” teachers by rigidly applying this Test to all secular professors, is either miserable cant, or it is a lamentable illustration of the proverbial truth, that the slightest points of difference, the fiercer and more intolerant is the tone by which ecclesiastical controversies are characterised.

The revived application, the modification, or the repeal of the Scottish University Test, are questions far too important and too extensive to admit of summary discussion. They have important bearings upon the interests of religion, science, and of general education in the northern division of the empire; but it is chiefly as involving the future destinies of the medical schools of Scotland that we have thought it necessary to call attention to them. It is our earnest hope that every one who loves his profession, and wishes to see the onward progress of medical science, will, within his own sphere, make known and denounce to the utmost of his ability the monstrous and mischievous monopoly which ecclesiastical bigotry, oblivious of the spirit and requirements of the age, is now seeking to create in Scotland.

ABUSE OF HOSPITALS AND DISPENSARIES, A MONSTER EVIL OF THE DAY.

Among the many evils which impede the progress of the medical man struggling with the world, there is none, which to a greater extent renders difficult even moderate success in practice, than the enormous increase of charitable medical institutions, and the indiscriminate manner in which advice and medicines are there supplied to all comers. Far be it from us to deny the great value and importance of Hospitals and Dispensaries, both to the profession and to the public, when proper rules are observed as to the class of patients admitted: but the truth must be spoken, and attention called to some prominent evils which arise from the present prevalence of indiscriminate medical charity.

That the labourer is worthy of his hire, is recognised by the public as a truth which offers but one exception, that exception being the Honorary Medical Officer of a public charity: he is called upon to devote his time and his talents to the patients placed under his care, and to be rewarded by a merely formal vote of thanks at an annual meeting, while the donation of a ten or twenty pound note, from the richest man in the county, is ostentatiously advertised, that the rustics may admire his munificent liberality. The toil-worn doctor who gives his gratuitous services, is supposed only to do his duty: but the wealthy donor, who suffers no inconvenience, is paraded as the poor man's friend.

Again, let us look at the remuneration offered to House Surgeons and Apothecaries at many of the metropolitan and provincial hospitals, and ask ourselves whether these hard-working servants of the public are not miserably underpaid.

We maintain that while hospitals and dispensaries, where

the number of patients is not too numerous, have been the means of doing good to the deserving poor, indiscriminate admission to the crowded out-patients' room has been productive of a vast amount of evil to the profession, and of little benefit to the majority of the applicants, on whom often only a minute or a fraction of a minute can be bestowed.

1st. The *out-patient system* diminishes the earnings of the physicians, surgeons, and general practitioners, practising within the sphere of the operations of a hospital. The yeomen of the neighbouring villages are in the habit of resorting to the nearest county hospital for medicines and advice: thus the rural practitioner loses his patient, and the hospital physician or surgeon is deprived of his legitimate consultation fee. In the metropolis, similar evils are equally rife. Gentlemen's servants, clerks, and well-to-do tradespeople with their wives and children absolutely encumber the waiting-rooms of the London hospitals: and it is chiefly in the Union Infirmaries that the really destitute sick are ministered to. Our larger hospitals and dispensaries are degenerating more and more every day into institutions for furnishing gratuitous medical advice and medicines to the servants and dependents of subscribers; while the minor establishments for special diseases are used principally (and often most unblushingly) as mere pretexts for advertising.

2nd. It tends to reduce the extra allowances of the poor-law medical officers. Boards of Guardians, in their advertisements, make a great flourish of trumpets with regard to these allowances; yet in many districts all extra cases that can be removed are at once transmitted to the neighbouring hospital; thus in a large Union, a subscription of two or three pounds saves fifty, the parish surgeon is deprived of his proper cases, and the hospital surgeon for his skill and attention receives nothing.

3rd. It tends to diminish the public estimation and proper money value of professional advice. This is self-evident.

4th. It injures the prospects of the rising men who practise in the neighbourhood. Of this we could furnish many painful illustrations. The young surgeon fresh from the schools seeks a large town, in which he has connexions, and in which he thinks that by industry and attention he may work out a practice; but he finds an opposition there which he little expected, in the county hospital, where a shabby exterior is all the recommendation required to obtain advice and medicine gratuitously; thither resort all the petty tradesmen and servants; while the Dorcas society provides their wives with gratuitous accoucheurs; and this opposition arises from the abuse of institutions, which, without the gratuitous assistance of his professional brethren, could not exist at all.

All honour to the men who gratuitously serve an ungrateful public! but we would ask them to pause in their work, to inquire whether they are not, by supporting the present system in its manifold abuses, injuring the profession as a body. It is the out-patient system against which we chiefly rebel; the indiscriminate admissions we would abolish, refusing assistance (except in cases of accident), to all not in needy circumstances. We would commence by driving forth, with indignation, from the waiting-rooms, the overpaid and pampered menials of the pseudo-charitable subscribers.

We have hitherto only glanced at some of the more patent evils of the present system as they affect our profession; but in a social point of view, the present mis-

chievous constitution of our hospitals and dispensaries has a still more momentous bearing : it *destroys or prevents the formation of provident habits among the poorer classes*. The man who knows that a charity is open to him whenever he wants a dose of medicine, is not likely to save money ; with him, sufficient for the day is the evil thereof ; and thus when his family are laid aside by sickness, the dispensary doctor is struck with the poverty of the den or garret, which, had not indiscriminate charity existed, might have been a comfortable home.

It may be said, that these growing and long-continued evils admit of no immediate or adequate relief. We would suggest a remedy, by asking two plain questions.

Why should the medical officers of public charities work gratuitously ? Why do they not combine together to memorialize the various committees and boards of governors to stop the present wholesale distribution of medicines and advice to out-patients ; or to adopt the alternative, of paying their physicians and surgeons a suitable salary for their attendance, and adequately increasing their number, so that the advice given, instead of being, as it now too often is, only nominal or routine, may be founded on an efficient examination of the patient.

We feel certain that there is scarcely a body of gentlemen acting as a hospital or dispensary committee, who would not feel that they were imperatively called upon to confront and reform existing abuses, were they to be thoroughly convinced of their actual magnitude.

SHABBY TRICKS OF THE GUARDIANS OF THE LEDBURY UNION.

THE mean devices by which "guardians" of the poor strive to snub, crush, and despoil Union Medical Officers, are so well known, as to have become proverbial ; yet that is no reason why we should not occasionally call attention to the tactics of these parties. Abuses must be unceasingly exposed, so long as they remain unredressed.

Before us lies, in the *Medical Times* of the 22nd instant, an advertisement of the Guardians of the Ledbury Union, in which, after stating the salaries they propose to give to their medical officers, they state ;—"The guardians will provide all drugs and appliances, and a competent person to dispense the same ; they also purpose subscribing to the Hereford and Worcester Infirmaries. No extra fees will be allowed." In other words, the subscribers to these charitable institutions are to be burthened with the maintenance of all the paupers who may sustain severe surgical injuries, while the hospital staff gratuitously attend to them, in order that they may save the ratepayers the paltry fees sanctioned by the Poor Law Commissioners to be paid to Union medical officers. We unhesitatingly declare, that county hospitals are not intended for such purposes ; and that their surgeons are not appointed to minister to such cases. The system cannot be defended ; and we think that if a firm remonstrance from the Association, or its Council, were made to the committees of these infirmaries, lasting beneficial results might flow to the Poor Law Medical Staff of the whole kingdom.

The numerous letters which we receive, bearing more or less on this point, constrain us to publish that this is a matter which requires more than statements and appeals in these columns. It demands decided, organized, and persevering action.

THREATENED RE-IMPOSITION OF THE INCOME TAX.

THE threatened re-imposition upon medical practitioners of their present unjust share of the Income Tax, ought to rouse not only their indignation, but their energies. On the 10th of February, Parliament meets ; and before that day there is abundance of time for the medical profession in every town in the kingdom to prepare petitions to both Houses, similar to those which have already been adopted at Torquay, and which we print at p. 93, along with a prefatory letter from Dr. Nankivell. The labours of Mr. Hume's committee have clearly proved the practicability of a more equitable adjustment of the tax ; and as it must at no very distant period be either revised or abolished, we call upon our colleagues to be up and doing.

ORIGINAL COMMUNICATIONS.

ON INFLAMMATIONS OF THE SCLEROTICA.

By WHITE COOPER, Esq., F.R.C.S.Eng., Ophthalmic Surgeon to St. Mary's Hospital, etc.

INFLAMMATIONS of the Sclerotica having been particularly rife during the last autumnal and winter months, I propose to offer a few practical remarks upon them.

The reason of their frequency in autumn, may be the action of the damp and cold then prevailing, on systems still feeling the effects of the summer heat. During the hot months the perspiration is active, but is checked by the chilly nights of autumn. If the atmosphere be *dry*, cold, no matter how intense, will not set up rheumatic inflammation ; but a cold fog is, as every one knows, especially favourable to its development. The electrical condition of our nervous systems is much influenced by moisture, and when the air is loaded with moisture, the insensible perspiration cannot be carried off with the same freedom as when the air is dry ; thus effete particles are retained which ought to be removed. In some persons, there is a tendency in the fibrous structures to take on inflammatory action under such circumstances, and the sclerotic, as one of them, evinces this in the affection Scleritis : and when this membrane has once been the seat of inflammation, the morbid action has a tendency to recur again and again when the exciting cause is in operation.

The tough, fibrous sclerotic has little sensibility in its normal state ; but when the vessels composing its areolar tissue swell under inflammation, the membrane yields to the distension slowly, obstinately, and with grievous pain. To a superficial observer, the inflammation appears much less severe than in conjunctivitis ; for in place of the bright crimson of the latter, the eye has a generally diffused pink hue, caused by the minute capillaries of the white sclerotic being gorged with red blood. On close inspection, there will be seen a series of straight vessels running from the periphery of the globe towards the cornea, separately at first, but inosculating at acute angles as they approach it ; these are manifestly deeper than the more tortuous vessels, which may always be seen coursing over the surface.

Whenever the sclerotic is inflamed, there is deep-seated pain of an aching, throbbing character. The globe feels too large for the socket, and is tender to the touch ; the pain is not confined to the eye, but extends to the temple, which is bruised and sore ; in severe cases the whole side of the head, even to the occiput, together with the brow and cheek, participate in the suffering. This is aggravated at night, and it is supposed that in true rheumatic cases the periorbital lining the orbit participates in the inflammation. Be that as it may, the patient is generally awakened about two in the morning by a paroxysm of pain, which gradually increases up to a certain point, and then as gradually subsides ; and this is repeated night after night, till the sufferer,

though jaded and weary, dreads the approach of bed-time, and the morning finds him tossing, feverish, and unrefreshed.

When the great vascular communication which extends from tunic to tunic of the eye is considered, we may readily conceive that inflammatory action commencing in the sclerotic is speedily extended to the other membranes. Accordingly, within a few days after the pinkness of the sclerotic manifests the presence of inflammation, the conjunctiva will redden, and the iris will be slightly changed in colour; for instance, a blue iris will assume a slight greenish tinge without perceptible dulness, and about the same time the patient complains of some mistiness of vision;—the pupil too will be rather contracted, and will not act freely. These symptoms indicate that the iris and choroid participate in the morbid action. When the iris becomes involved, the characteristic zone around the cornea becomes strongly marked, being gradually shaded off into the general pink of the sclerotic, above which a pretty close network of inflamed conjunctival vessels can be seen.

At the first onset of scleritis the whole membrane is not suffused at once; a patch, generally near the cornea, first becomes injected, and from this the inflammation, if not checked, rapidly extends.

Being desirous of ascertaining the relative frequency of scleritis in different places, I have compared the reports of the Liverpool, the Bristol, and the Moorfields Eye Infirmarys; and taking the average of three years, 1846, 1847, and 1848 for each, I have found that the proportion of rheumatic cases was to the whole number of cases as follows:—

At Liverpool	1 in 128.29
Bristol	1 in 71.53
Moorfields	1 in 53.64

According to M. Cunier, the proportion of rheumatic cases in Belgium is about twenty-two per cent.—an enormous proportion, fully bearing out his statement that, in order of frequency, rheumatism stands next to scrofula as a disease of the poor in that country; and we cannot fail to remark, that the proportion is greater in London than in either Bristol or Liverpool.

Besides the simple form of scleritis which is excited by local influences, there is another which is really the development of rheumatic inflammation in the eye, and is independent of local causes. During the last spring, I was requested to see a patient of Dr. Sibson's in Victoria-ward, St. Mary's Hospital. On a bandage which covered her eyes being removed, I recognised acute rheumatic inflammation of the right eye; and on inquiring for what disorder she was admitted, was informed that she was then confined to bed by acute rheumatism of the joints, and that the inflammation of the eye had come on since her admission, being, in fact, metastasis to that organ. It is, however, more common to find the eye affected after the general attack has passed away. Mr. Middlemore thus describes the conditions which usually govern the invasion of rheumatic scleritis.

"Rheumatic scleritis," says he, "takes place most commonly independently of the present existence of any rheumatic affection, but not independently of the former existence of rheumatism; and in very many instances it would seem to be vicarious of rheumatic inflammation elsewhere, for, although rheumatism in some other part of the body may have been somewhat severe at the time of its occurrence, its severity has declined as the disease in the eye has progressed, and when fully established in that organ, it has wholly disappeared in its original site. I have known a severe attack of rheumatic scleritis supervene upon an acute rheumatic affection elsewhere, and continue in both situations with great severity; but this is very unusual, and presents a rare exception to the general rule upon this point. In other instances, rheumatic scleritis has distinctly alternated with rheumatism in some other part, the one texture resuming, or, to use a familiar phrase, taking up the action the other texture had declined."*

The following cases illustrate these positions.

CASE. On the 14th of last September, a member of Par-

liament, about 36 years of age, consulted me under the following circumstances. During the late Session of Parliament, he had suffered severely from the currents of hot and cold air, which play in a most eccentric manner on the members of the House of Commons, giving rise, in his case, to general rheumatism of the muscles of the body; so that, as he expressed it, "Whether sitting or lying, there was no posture in which he was not in pain." After trying a variety of treatment he went to Buxton, and had derived considerable benefit from the bathing there, when suddenly, and without apparent cause, his right eye became attacked with inflammation, which for a fortnight completely bade defiance to the active general measures, and local sedatives and astringents, with which he was treated. At this point I shall leave the case, referring to it again when speaking of the treatment of rheumatic inflammation.

CASE. On the 6th of the present month, Susan Jandrell, a spare woman, 78 years of age, applied to me at the North London Eye Infirmary. Her right eye presented a well-marked example of rheumatic scleritis. On asking how long she had had it, she replied, "Oh, sir, this is one of my old attacks: for the last seven years I have every autumn had an attack of rheumatism, and as soon as my limbs get well my eye always becomes bad." I might adduce many more examples, but these are sufficient for my purpose.

The symptoms in rheumatic inflammation differ in no great degree from those which have been described as characterising the simple form; the colour is perhaps more dull, more brickdust-like, and the redness more patchy than in ordinary scleritis, but according to my experience the rheumatic form is by far the most troublesome to deal with. In the first place, its obstinacy is great. The surgeon is sent for to a patient labouring under this disorder; his treatment is attended with the most pleasing improvement, and the eye gets nearly well. He congratulates himself on the speedy cure effected; when, on calling, he finds the room again darkened, and the eye bound up. "Oh," says the patient, "my eye is as bad as ever: I've had a dreadful night; I went to bed quite comfortable, but awoke about two, and have not had a wink of sleep since." The examination of the eye quite confirms the assertion of the patient, that the inflammation is as bad as ever, and the whole battle has to be fought over again; and this will sometimes happen twice or thrice, until the patient is utterly disheartened, and the medical attendant perhaps not less so.

There is another feature of rheumatic scleritis, which is very troublesome. After the inflammation has existed some days, a little ulcerated furrow, surrounded by a slight haze, is seen near the margin of the cornea. This is very apt to extend, until there is a troublesome superficial ulceration, attended with considerable haziness, involving, perhaps, half the surface of the cornea, and materially interfering with vision. I believe this is most frequently found in persons of feeble constitution, and whose systems are debilitated either by disease or by excesses. In such, weeks and even months will elapse before the eye perfectly recovers, as in the following case.

CASE. On the 11th of last May, I was sent for to a lady, seventy-one years of age, who had during the last seven years suffered from four attacks of rheumatic inflammation of the left eye, two of which had respectively lasted three months, and three months and a half. The outer half of the sclerotic was of a dull red, the eye felt bruised and sore, and there was pain of the brow. Six leeches were applied to the temple, frequent fomentations ordered, and after the secretions had been corrected, bark and soda with colchicum were prescribed. The eye gradually became better; and on the 20th, I took my leave.

On the 24th, I was again sent for, and found a slight return of the inflammation, but so trifling, that I again took my leave on the 26th, the eye being apparently well.

On the 31st, I was again summoned, and this time found a rather sharp return of the inflammation, with ~~business~~ and several small superficial ulcerations on the ~~cornea~~; but by the 10th of June, all had subsided, with the ~~eye~~.

* Middlemore, "Treatise on the Diseases of the Eye", vol. 1, p. 568.

tion of slight haze, which was gradually disappearing, in the cornea.

A month afterwards, the eye experienced a slight return of inflammation, and the abrasion of the cornea reappeared, nor did it yield readily to treatment. The weather was at this time oppressively hot; and being satisfied that change of air would be beneficial, I sent this lady to the Isle of Wight. Within a day or two after her arrival there, an improvement in the symptoms was apparent. It continued, and the eye gradually recovered; so that when I saw it at the expiration of five weeks, the faintest possible haze alone marked the seat of the troublesome ulceration of the cornea.

In connexion with this case, I may mention a little incident so characteristic of the late Duke of Wellington, that I will venture to relate it.

Soon after the second attack of inflammation had subsided, but whilst the eye was still uneasy and intolerant of light from the ulceration, my patient said to me one day on making my call, "Mr. Cooper, the Duke of Wellington and I are very old friends; and hearing that I was suffering from my eye, he called yesterday, bringing with him a bottle of eye-water, which he said he was quite sure would cure me if I would use it, for he had used it himself daily for twenty years, and entirely attributed the preservation and strength of his sight to it, but I said I would not apply it without your permission."

I smiled, and asked if her ladyship knew its composition?

"Oh, yes," said she, "the duke told me that it was equal parts of vinegar and rose-water; and the way he uses it is this:—he dips his finger in it every morning, and sweeps the moistened finger round the eye two or three times, not letting any of the eye-water get into the eye; and he is perfectly confident that if I will do the same, my eye will soon be well."

I told her ladyship that so far as I was concerned, she was at perfect liberty to use it in the way described; but I had great misgivings as to the favourable result so confidently predicted by my illustrious rival.

There is a peculiar condition of the eye occasionally seen in old persons who have been martyrs to chronic rheumatism, especially that form in which the joints of the fingers have been slowly disorganized, giving these extremities the appearance of birds' claws.

Without other pain than dull aching, a morbid action will be set up in one of their eyes, of which the appearances are as follows. The sclerotic gradually loses its natural appearance, and assumes a purplish dingy brown hue, most marked in the neighbourhood of the cornea; after the lapse of many months, it may be seen to bulge a little—not equally, but more on one side than the other. The iris becomes dull and rather discoloured; a few purplish vessels may be seen ramifying on the surface of the sclerotic, and the patient complains that the sight has become very imperfect. In such cases there has been chronic inflammation, giving rise to effusion, which effusion, causing absorption of the sclerotic, permits the dark hue of the choroidal pigment to be seen through the attenuated membrane—whence the colour. The same pressure, at a later period, produces the bulging projection. I believe that the choroid is always implicated in these cases, and that the local changes being in connexion with constitutional mischief, are very little amenable to treatment.

Authorities differ widely as to the line of treatment proper for scleritis; but perhaps too much attention has been paid to verbal distinctions, and too little to the broad principles which should guide us. We ought not to consider ourselves bound down to one line of treatment for scleritis, to another for conjunctivitis, to a third for iritis, or to yet a fourth for choroiditis. A practitioner who allows himself to be trammelled by mere names, places himself in a false position. We should first look to the affected organ, and carefully ascertain the extent to which the inflammation has proceeded. Having satisfied ourselves on this point, we should not less carefully examine into the general condition of the patient, obtaining all the collateral

information as to constitution and habits that can be acquired; and on the combined information obtained in this manner, we should direct our proceedings, irrespective of mere names. I have been led to these remarks by the different directions laid down in books as to the treatment of scleritis. One authority would treat it exclusively by attacking the morbid condition of the system; another would confine its treatment to local measures; then, again, some would bleed from the arm very copiously, whilst others condemn even the moderate use of leeches. The truth is, that every case ought to be made a study of itself, and should be treated according to its requirements. As a general rule, there can be no doubt that judicious depletion, by cupping or leeching, is beneficial. The vessels are thereby unloaded, and brought into a favourable condition for responding to the action of medicines; and I may remark, that the mastoid region is preferable to the temple for the abstraction of blood. The bruised and tender feeling of the temple, which is characteristic of scleritis, renders cupping on that spot a very painful proceeding, and leeches occasionally cause much irritation and erythematous swelling, when applied there; these objections do not apply to the mastoid region, and the relief is equally great when the blood is taken from thence.

As regards general treatment, much will, of course, depend on the condition in which the patient is found. The bowels should be well cleared in the first instance, but afterwards mere purging does little good. The point to be held in view, should be correction of the secretions, and regulation of the bowels, rather than active purgation: no less important is it to maintain an action of the skin, by doses of Dover's powder, or James's powder, where the surface is dry. A valuable medicine, after the tongue has become clean, is bark and soda, five grains of each of which, combined with two of powdered colchicum, or without the colchicum, may be given thrice a day with the happiest effect. The iodide of potassium, too, often exerts great influence over scleritis, especially after it has become chronic. From three to five grains thrice a day, in a light bitter infusion, as that of hop, will often remove the lingering inflammation with great rapidity.

Space will not admit of my dwelling upon the treatment, but I must, in conclusion, allude to a remedy which, at the suggestion of my colleague, Mr. Ure, has recently been employed by me. I mean benzoic acid; and I will briefly narrate the circumstances under which it was tried. It was in the case of the Member of Parliament already referred to. His condition, when I first saw him, on the 14th September, was as follows. The conjunctiva and sclerotic were intensely inflamed, the corneal zone being strongly marked. The iris, naturally blue, had a green tinge, but was not otherwise altered; the pupil was contracted, and sluggish; the globe excessively tender; he had much mistiness of vision, intolerance of light, and profuse discharge of scalding tears. There was great supraorbital pain, involving the whole side of the head, and greatly aggravated at night. This state of things had existed a fortnight, and he was very low, with cold skin, and feeble pulse.

The history of the case, and the symptoms, indicated rheumatic scleritis, which had gradually involved the iris and the choroid; and I thought it a favourable opportunity for trying benzoic acid. Six leeches were first applied to the mastoid, and he was then ordered to take half a drachm of powdered benzoic acid thrice a day. He began this on a Tuesday. On the Thursday there was a manifest improvement: he had passed a good night, and could face the light; whilst the local inflammation had materially decreased. The powders were stopped on the Friday, as he complained that they made him sick; the improvement, however, continued. The only other medicine ordered, was a little grey powder; and on the Monday following—the sixth day after fairly commencing this treatment—the patient left town with his eye almost entirely free from redness, and with merely some haze of vision, all which symptoms, I subsequently learnt, disappeared in the course of another week.

19, Berkeley Square, January 1853.

REQUIREMENTS IN METEOROLOGICAL TABLES.

By W. ADDISON, M.D., F.R.S.

THE quarterly returns of marriages, births, and deaths, contain mean readings of the thermometer, barometer, etc.; but, in order to estimate correctly the influence of weather upon sickness and mortality, it seems to be the extremes, which often occur within very short periods, that are required.

It is generally understood, that sudden alterations in the weather are prejudicial to health; nor can there be any doubt of this fact; yet such alterations are frequently obliterated by averages and means. The means of a month or a week may come out nearly alike to those of the preceding week, or of the corresponding month of the preceding year, and yet include very extensive thermometric changes, which are thus placed out of view. Every one, in his own person, is acutely sensible of a change of temperature from 50° to 24° , and *vice versa*. This may occur, and has occurred, without altering the averages of the month more than 1° or $1\frac{1}{2}^{\circ}$. In projecting a meteorological diagram, the mean curves are rounded off and depressed; whereas, what seems to be required are the extreme limits and the time.

I will give one or two examples of my meaning, from a manuscript meteorological journal now before me, embracing observations made four times a day.

It is at night, when going to bed, and in the morning, when we first encounter the outward air, that sudden changes in the weather are most acutely experienced. Let us take, then, 9 o'clock A.M. for our illustration.

On the 6th of January, 1835, at 9 in the morning, the thermometer out of doors stood at 34° F.; on the 7th, at 27° ; on the 8th, at 24° ; on the 9th, at 40° ; on the 11th, at 48° : the barometer falling, in the same interval of time, eight-tenths of an inch.

Turning to the bills of mortality for the metropolis, to find the effect, if any, of this sudden change, we find, in the week ending January 6th, the deaths from scarlet fever, 7; from measles, 15; and from hooping cough, 15; whereas, in the week ending the 23rd (when the influence of the vicissitudes of temperature between the 7th and 11th of the month might be expected to appear in the mortality table) we find the deaths from scarlet-fever, 14; from measles, 23; and from hooping-cough, 18. In the two former instances, the mortality was doubled. The inference is, that cases of sickness were both aggravated and largely increased.

Again, in April 1835, we meet with another remarkable example of a sudden depression and rise of temperature, and of the dew-point, as ascertained by Daniell's hygrometer. On the 14th of the month, the dew-point, at 9 A.M., was 50° ; on the 16th, at the same hour, it was 25° ; on the 17th, 28° ; and on the 18th, 42° . The thermometer, in the same period, ranged from 61° on the 14th to 28° in the night of the 16th—a range of 33° .

Turning again to the bills of mortality, we find, in the week ending the 28th April, an increase in the burials, as compared with the preceding week, of 332. The deaths from consumption were double: fever, scarlet-fever, measles, hooping-cough, and inflammation, being the other heads under which there was a large increase.

April we expect to be a month of genial, warm, moist, spring weather; but, as above shown, it is subject, for 24 or 48 hours, to a temperature and a dew-point appropriate only to the depth of winter. Sudden and temporary these changes may be, and are: and this is the point of the present communication. They are so sudden and temporary, that they disappear in the monthly means; and may even be lost sight of in the average of a week; but they are not so sudden or short-lived as not to have a powerful influence upon the origin and progress of epidemical distempers.

It is concluded, from the facts stated, not only that sudden atmospherical vicissitudes have a great influence upon the progress of sickness and the amount of the mortality,

but also that meteorological tables do not fulfil their proper function with reference to epidemic diseases, unless they show the full extent or the extreme points of all the most prominent or sudden atmospherical changes, and define or give a measure of the time they include.

Maldstone, Jan. 15th, 1835.

ON THE NATURE AND CAUSES OF THE PHYSIOLOGICAL PHENOMENA

COMPRISED IN THE TERM "MOUNTAIN SICKNESS"; MORE ESPECIALLY AS EXPERIENCED AMONG THE HIGHER ALPS.

By STANHOPE TEMPLEMAN SPEER, M.D.

(Concluded from p. 53 of last number.)

THE abnormal sensations constituting mountain sickness may thus be classed in a tabular form, according as they affect the different functions.

Of the nervous system.	{ Vertigo. Cephalalgia. Somnolence.
	{ Dyspnœa. Increased rapidity of the respiration. Sense of thoracic constriction.
Of the respiratory and circulatory systems.	{ Occasional oozing of blood from mucous surfaces. Syncope tendency. Cardiac palpitation. Throbbing of the vessels within the cranium. Increased rapidity of pulse.
	{ Anorexia. Nausea and vomiting.
Of the digestive functions.	{ Thirst. Constriction below the epigastrium. White tongue.
Of the locomotive functions.	{ Muscular pains. Paralysed sensation in the lower limbs.
Of the tegumentary system.	{ Harsh skin. Suppression of the cutaneous transpiration. Pallor of the surface. Cyanosed appearance of the countenance.

It must not be supposed that all these symptoms are to be met with in every individual, upon his attaining a considerable elevation; but in one instance or another, they have each and all been noticed in ascending the Mont Blanc. While, in the different accounts given by those who have reached its summit, we meet with many different opinions relative to the physiological phenomena there observed, some asserting that nothing unusual was felt, others, that this or that symptom was the most prominent and unpleasant, all such diversities of opinion as regards personal sensation are to be estimated at their real value, and not to be set down as indicative merely of the workings of imagination. No one doubts the influence of the sea upon those unaccustomed to it; but if a given number of such persons be taken promiscuously, there will be a great probability of receiving from them at least three or four different versions of its effect. One individual will complain of excessive nausea, without the relief afforded by vomiting; with another it will be exactly the reverse, fits of vomiting occurring, with perfect ease during the intervals; in a third, diarrhoea and abdominal uneasiness will be the prominent symptoms (of this I know several examples); a fourth will complain chiefly of severe headache, with or without gastric complication; a fifth may suffer from a combination of the above miseries; while a sixth, without obvious reason, will enjoy a complete immunity from them all. But further, these varieties in the effects produced by the motion of a vessel at sea are not only met with in different individuals, but they may occur in the same one, at different times, and under different circumstances, according to the state of health he may have previously enjoyed.

Upon the same principle may be explained the diversity of symptoms, and at the same time the occasional immunity from them, at a given elevation which may exist in differ-

ent individuals. Reference is to be made to their physical peculiarities and antecedents.

The causes which give rise to the phenomena of mountain sickness, next claim attention.

The earliest attempt to explain the occurrence of these symptoms, was made by De Saussure; he asserts that they are due, not to the difficulty of breathing in such an atmosphere, but to the relaxation of the vessels, which arises from a diminution in the compressing power of the air. After ascending the Mont Blanc, he says, "the respiration is inevitably accelerated in a rarefied atmosphere, by the necessity of supplying the lungs with the same quantity of air in a given time", and he adds, "this forced acceleration of the respiration is the cause of the fatigue and distress experienced at great elevations, for, as the respiration becomes quickened, the circulation becomes so likewise." He further says, "the muscular exertion, moreover, produces, in a rarefied atmosphere, an acceleration of the circulation and respiration, extremely annoying to certain temperaments."

In a paper published by M. Brachet, in which he endeavours to elucidate the causes which give rise to certain of the phenomena occurring upon lofty mountains, it is justly observed that, in America and Asia, the effects of a rarefied atmosphere are only first perceived at the limits of perpetual congelation, although these limits differ considerably in point of elevation according to the latitude of the locality. In the opinion of this author, the lassitude and dyspnoea are explicable upon the following theory. "During the act of locomotion, those muscles which are contracting remove the oxygen of the blood which traverses them more rapidly than those which are at rest; hence the necessity for an accelerated respiration, in order to supply the deficiency produced by such movement, more especially in a rarefied atmosphere, and the relief from the dyspnoea thus produced upon taking rest, when the blood, losing less of its oxygen in the muscles, requires less in the lungs."

"On the other hand, as the muscles can contract only under the influence of arterial blood, it follows that, when the blood which reaches them has become venous, they are struck with a certain degree of paralysis; and hence the difficulty, amounting at length almost to an impossibility of locomotion, when on lofty mountains the muscles which perform this function, and consume at the same time a considerable quantity of oxygen, receive at length blood containing but little oxygen, and all but venous in its character."

From the above theory it would appear, that the physiological phenomena in question are attributed solely to changes in the quality of the blood. Such a view, however, is somewhat too exclusive.

It is here worthy of remark that, after attaining a height of 13,000 feet and upwards, the necessity for a frequent halt will arise in one person from extreme dyspnoea, rather than from fatigue, while another will halt less from want of breath than from a loss of power in the lower extremities, and a conviction that a fall would be the result of an attempt to proceed further. Rarely indeed is the dyspnoea so urgent but that it would permit of a few more steps being taken, were it not that muscular power fails entirely.

To those who have known what it is to make protracted extension upon a fractured limb, to compress an artery during a tedious operation, or to engage in the exercise of fencing, this species of muscular incapability will be familiar. While, under the above circumstances, the respiration may be unembarrassed, the individual ere long will perceive in the contracted muscles a painful sense of fatigue, and the fingers would soon refuse to do further service, were their strength not recruited by being allowed to relax somewhat. The same result takes place at a great altitude, only with greater rapidity; but it is possible (as will be seen) to become so accustomed to a rarefied atmosphere, as at length to feel no unpleasant effect therefrom: and were this muscular incapability the result of increased venosity

of the blood, from habitual deficiency of oxygen at such heights, it is doubtful whether it would be so easily and rapidly removed by habit, nor would such a condition be accompanied by actual pains in the limbs.

It is probable, therefore, that this painful species of fatigue depends upon sanguineous congestion, occurring in those muscles which are in the act of contraction: and the general character of the phenomena, which result from rarefaction of the atmosphere, appears to corroborate this view.

In proportion to the rapidity of the circulation, does the tendency to active congestion increase; now, at a great elevation, this increased rapidity does actually take place, as evinced by the greater frequency of the pulse, without any reduction of its strength; in such a case, the liability to congestion is sufficiently evident. Upon refraining, however, from exertion, or at least by diminishing the amount of effort, the proper equilibrium may be recovered and maintained, in persons of a tolerably robust constitution; but upon again moving, the contracted limbs become, *de novo*, the seat of congestion, and this increases in proportion to the acceleration of the circulation. It may here be remarked that, in a rarefied atmosphere, those whose muscles have been most exercised are less liable to these sensations.

That the pains felt in the back and loins under such circumstances are due to congestion, is, I conceive, rendered still more probable by their similarity to those which are felt at the commencement or cold stage of a febrile paroxysm,—a period when there in reality exists a congested condition of the internal organs.

The dyspnoea and semi-paralysed condition of the extremities thus produced, are usually associated with certain other phenomena, the *ensemble* of which alone deserves the appellation of "mountain sickness"; these are nausea, anorexia, a syncopal tendency, experienced especially when the trunk is not inclined forward, severe headache, oozing of the blood from the gums, as noticed by Humboldt, etc., etc.; and these symptoms may (like the dyspnoea and muscular debility) be attributed in a great degree to the same cause—irregularity of the circulation, with congestion of the cranial and abdominal viscera.

The usual result of ordinary muscular effort is to produce a stasis of blood in the capillaries, and a condition of active congestion in the brain, lungs, and muscles. Upon making a series of such efforts without intermission, as, for example, when indulging in violent gymnastic exercise for some minutes consecutively, in running hurriedly up a long flight of stairs, or a steep ascent, the same effect is produced to a still greater extent; and if such exercise be at all prolonged, the sight becomes dim and troubled, giddiness and vertigo supervene, with a painful sensation of lassitude and complete failure of the muscular powers. If, however, repose be taken before the effects of pulmonary and cerebral congestion have attained their maximum, there occurs a reflux of blood towards the heart, evinced by sudden paleness of the countenance, a sensation of faintness, troubled vision, and even complete syncope; unless the precaution of assuming the horizontal posture be immediately taken.

Such are the ordinary consequences of violent exertion, as occurring within the scope of general observation. They are evidently due not merely to the inordinate stimulation of the muscles by a surplus of arterial blood, in their earlier stage, or to the paralyzing effect of venous blood at a subsequent period, but likewise to the cerebral excitement produced by an increased afflux of that fluid towards the brain, its rapid subsidence from which leaves the sensory and motor powers in a state of comparative collapse.

Upon comparing these phenomena, evidently arising from temporary sanguineous congestion and its sequelæ, with those observed at great altitudes, the similarity becomes apparent, and in fact unmistakable; with this difference merely, that the rarefaction of the air, in accelerating the movements of respiration, even during repose, contributes to develop the ordinary results of exertion with greater rapidity than in the plain.

The next most prominent symptom, noticed as occurring

at great altitudes, is a condition of the stomach resembling in a great measure that which is familiar to all who have experienced the pitching motion of a steam-vessel in a short cross sea. It is this phenomenon to which the term "mountain sickness", in contradistinction to that of "sea sickness", is especially applicable, as constituting frequently the most prominent and distressing symptom during the ascent of a lofty mountain. It is true that it seldom attains such a degree of severity as that felt at sea; but it nevertheless produces, when well marked, the greatest prostration, and that sense of general depression which accompanies nervous headache with gastric derangement.

It is evident that the causes giving rise to this condition of the stomach cannot be classed under the same head as those to which the analogous phenomena of sea sickness are attributable. In the latter case, it is probable that the real cause lies in a disturbance of the brain, produced by the continued motion of the vessel, and affecting the sense of vision in a manner to which it had been previously unaccustomed. In sea sickness, therefore, the stomach would appear to be secondarily implicated as the result of a morbid impression transmitted to the brain; and that such is the actual explanation of this distressing affection, seems warranted by the peculiar nature of its premonitory symptoms, which are evidently of cerebral origin, and by the fact that the same phenomena in a modified form are experienced by some individuals, upon looking at an object perpetually moving before the eyes. I have, in my own person, while steadfastly gazing at one of the long moving panoramas so popular at present, perceived at length a dimness of vision, with the same trifling giddiness and even tendency to nausea, which usher in sea sickness. These ceased, however, upon closing the eyes; and the efficacy of this measure at sea, more especially if accomplished through the intervention of sleep, would afford further grounds for presuming that in sea sickness the unaccustomed impressions, received by the eye and transmitted to the brain, should, through the well known sympathy existing between these organs, secondarily affect the stomach.

But while the mountain sickness resembles, in a mild degree, that felt at sea, its explanation must be otherwise sought for; and while saying that the two conditions resemble each other, it is necessary to add that in some particulars they differ. The cerebral symptoms are less prominent in the mountain variety,—there is less nausea, and actual vomiting is not common, unless the stomach have been previously deranged; nor is there that extreme sense of prostration and wretchedness which characterizes severe sea sickness, and which renders the sufferer totally careless, for the time being, as to what may be the result.

In an ordinary state of health, there exists in the intestines a certain quantity of gas, intended to counteract the pressure of the external atmosphere upon the parietes of the abdomen. At a given height this pressure becomes diminished, the gas undergoes gradual dilatation, and, according to the theory of M. Maissiat, by its pressure upwards upon the stomach, produces those symptoms of gastric derangement previously mentioned.

To this theory of Maissiat it might, as M. Le Pileur remarks, be objected, that these gastric symptoms are not accompanied by colicky pains, nor any marked sensation of abdominal uneasiness, such as often occur in ordinary cases of gaseous distension. It should, however, be remembered that those cases of flatulence are the most distressing, in which unaccustomed gases, or those occurring naturally in small quantities, such as sulphuretted and carburetted hydrogen, are largely developed within the intestinal canal; pure nitrogen and hydrogen may exist to a considerable extent without producing much abdominal uneasiness, more especially if, as is usually the case, they are secreted gradually. In the present instance the distension is not the result of the abnormal increase of irritating gases, but arises rather from the suddenly augmented bulk of those innocuous gases, which even in a natural condition are tolerably abundant within the intestines.

It has been by some supposed, that this gastric derangement is attributable to a general condition of the system, analogous to that which precedes an ordinary febrile attack. Others, on the contrary, deny this; they argue that the occurrence of the symptoms at a certain height, without appreciable cause, and their disappearance upon regaining a lower level, prove their non-dependence upon aught of a febrile nature. They assert that, beyond the disordered condition of the stomach, there are no feverish symptoms, the whiteness of the tongue and the acceleration of the pulse excepted; that the latter, moreover, presents no irregularity, or other peculiarity, further than that which occurs after taking moderate exercise, and that the whiteness of the tongue is attributable to the small amount of food taken on such occasions. They who deny the analogy between the two conditions, also affirm that during these ascents, there is never experienced that *malaise, sui generis*, which precedes a febrile paroxysm; and they explain the occurrence of thirst, by the evaporation which takes place with great rapidity in the upper regions of the atmosphere.

It would, I think, appear from this, that those who have advocated the non-identity of the physiological states giving rise on the one hand to the mountain sickness, and on the other to the congestive stage of an ordinary febrile attack, must have shut their eyes to the real facts of the case; for the very attempt to explain away each symptom which is known to attend the incubation period of a fever of non-specific origin, is a proof of the force with which the idea must have suggested itself. The symptomatic analogy between these two conditions may be seen by placing their respective phenomena in juxtaposition. I chose ephemeral fever as being the type of an ordinary febrile paroxysm.

Prodromic Phenomena of Ephemeral Fever.

1. General feeling of languor and distaste for motion.
2. Muscular pains in the loins and lower extremities.
3. Nausea, anorexia.
4. Headache, throbbing of temples.
5. Thirst.
6. White tongue.
7. Dry, rough blanched skin.
8. Acceleration of pulse.
9. Ditto of respiration.
10. Diminished general secretion.

Phenomena of Mountain Sickness.

1. Prostration with loss of power.
2. Muscular pains in the lower extremities.
3. Disgust for food, nausea and vomiting.
4. Headache, throbbing of carotids; vertigo.
5. Thirst.
6. White tongue.
7. Cold dry state of the cutaneous surfaces.
8. Increased rapidity of pulse.
9. Ditto of respiration.
10. Diminished secretion.

The above shews clearly the close resemblance which exists between the early symptoms of an ordinary feverish attack, and those which characterize the mountain sickness; but this is still further demonstrated, when the conditions of the system which accompany each, are taken into account.

In the early stage of ephemeral fever, which, as the type of simple fever, is best suited to the comparison in question, the symptoms point to a deficiency of blood in the external parts of the body, and, as a consequence, its accumulation in the deeper seated organs.

With the predisposing cause of this condition of the circulation in the prodromic period of a fever, we have nothing to do: various theories have been suggested to account for it. What may be looked upon as tolerably certain is that (whatever be the cause) there exists, as the prominent feature in the phenomena of mountain sickness, a congested condition of the internal organs, with a deficient cutaneous circulation; or that, in other words, while the two affections agree as regards symptoms, they each present an analogous state of the circulation sufficient to account for such symptoms.

The idea here suggests itself, that were it desired to produce such a pathological condition in a healthy individual, there could scarcely be a more efficacious mode of doing so than by suddenly removing him from a temperature of between 70 and 80 degrees of Fahrenheit, to one in which

he would be surrounded by fields of snow and masses of ice; in fact, to the regions of perpetual winter; and this in reality occurs in the case of those who attempt to ascend the loftiest of the Alps. At a height of between 1,000 and 2,000 feet, the traveller possibly spends a few days, buried as it were in a deep valley, suffering from intense heat and constant copious transpiration: upon leaving the valley he ascends rapidly, and in a few hours enters upon a region of eternal ice and snow, the vital heat being rapidly abstracted by the frozen material under his feet, and the power of advancing with sufficient rapidity to sustain the equality of the circulation, becoming hourly less and less.

This leads to a consideration of the somewhat singular fact, that the mountain sickness commences only at the limit of perpetual congelation, whatever that limit may chance to be.

Albeit liable to exceptions, the rule holds good in the majority of instances; for it may be seen, by referring to the narratives quoted previously, that among the Andes and Himalaya, the phenomena of mountain sickness are first noticed at an infinitely greater height than among the Alps, where the snow level is considerably lower.

The following is the most probable explanation of this anomaly.

In all mountainous countries, the habitations of men are to be met with, up to within a short distance of the line of perpetual congelation. To reach this limit from the sea-level, often requires, especially in the Andes and Himalaya, some days; upon attaining it, a short time is usually allowed to elapse, previous to entering upon the ice-bound desolate regions which now present themselves, and in this manner, an opportunity is afforded for becoming habituated to the increasing rarefaction of the atmosphere; but as, upon leaving the domain of man, it is necessary to achieve the remainder of the ascent as quickly and with as few stoppages as possible, it is evident that the rapid elevation through 5,000 or 6,000 feet, from a point where already the effects of a rarefied atmosphere were slightly felt, must produce marked results. It must tend at once to develope rapidly those abnormal sensations which had previously remained in abeyance, owing to the more gradual atmospheric transitions experienced in ascending from the level of the plains, across the succession of table-lands and lower mountain ranges, which lie at the foot of the loftiest and steepest summits.

It is for this reason that some of the Alpine passes, the St. Bernard to wit, give rise, not unfrequently, to an amount of mountain sickness and indisposition, scarcely explicable upon the grounds of absolute elevation. In this case, a height of 7,473 feet is attained in one day; and the traveller, a few hours after leaving the valley of the Rhone, sleeps at a height of $1\frac{1}{2}$ mile above the level of his previous night's resting-place. The sudden change in the density of the atmosphere between the two points, is quite sufficient to produce the phenomena in question, more especially in the uninitiated.

That it is not so much the absolute as the relative elevation attained, which causes the mountain sickness to be felt at much lower points among the Alps than among the Andes, is evident from facts, which show the possibility of individuals living without discomfort at heights, where, if suddenly removed to them, they would have experienced the most distressing sensations.

On the Thibet side of the Himalaya mountains, are to be found villages of 13,000 feet above the sea level; and likewise upon the slopes of the Andes, at 11,000 feet; and M. Humboldt mentions the fact of having lived for some time at a height of 12,303 feet, on the Antisana, without suffering in any way from the rarity of the atmosphere, the effects of which he was not sensible, until he had attained an elevation of 16,800 feet upon Chimborazo.

In M. Agassiz's travels and excursions among the higher Alps (*Excursions et Sejours dans les Hautes Alps*), he describes the mode of life led by himself and his companions, at a height of 7,800 feet, during the space of several weeks. From being frequently in the habit of ascending the neigh-

bouring peaks, they were at length enabled to reach the summit of the Jungfrau, without being annoyed by the rarefaction of the air. And D'Orbigny, in speaking of the sufferings he endured among the Andes, tells us that persons born in these lofty regions feel no inconvenience, while those who, after leaving the plains, reside for any length of time among them, suffer, it is true at first, but recover their usual health ere long, of which he himself afforded a personal and convincing proof.

In the accounts which we possess of some of the most remarkable mountain ascents, comparatively little notice appears to have been taken of the condition of the pulse. Not a few have been contented with asserting that it was somewhat quicker than usual, or did not vary to any great degree. Of the value of such loose statements, little need be said.

To the indefatigable De Saussure, however, we are indebted for some interesting remarks upon this subject. After remaining for several hours on the summit of Mont Blanc, he made some observations upon the pulse. His guides, as well as himself, were entirely free from the exhilarating influence of spirituous liquors; they had for some time been in a state of rest, and suffered merely from prostration and nausea. The pulse of De Saussure himself was found to be 100; that of his servant 112; and that of Balmat, his chief guide, 98. At Chamounix, the following difference was noted:—

	Chamounix.	Summit of Mont Blanc.
Saussure	72	100
Servant	60	112
Balmat	49	98

The same observer, at the close of his sojourn upon the Col du Géant, upwards of 11,000 feet in height, examined the ratio between the pulse and the respiration in his own person. In the morning, when at rest, he found the respirations 17, and the pulse 79, per minute. The next day, at noon, the pulse beat 82 in the erect, 83 in the horizontal posture.

Among those who ascended the Mont Blanc in company with Dr. Clark, it is said that the average variation of the pulse was from 4 to 30 pulsations per minute, at a height of 7,299 feet; and that this variation appeared in no way to depend upon the natural muscular powers of the individual.

Dr. Parrot, the well-known Russian traveller, in his ascent of Mount Ararat, reports that his pulse, which in the plains was about 70 per minute, was, at a height of 4,752 feet, 80, and at a height of 11,739 feet, 110 per minute.

In attempting to scale the Monte Rosa, Zumstein, who was accompanied by seven hardy mountaineers, varying from 20 to 60 years of age, found that at a height of 13,662 feet, the mean average for the seven was 85 pulsations per minute. He has unfortunately, however, omitted to mention the average of the pulse in these men before leaving the plains.

In the account given (*Annales de Chimie et de Physique*, vol. lii.) of the celebrated balloon ascent of M. Gay Lussac, we find that in Paris his pulse beat 62 per minute; that of his companion, 79. At a height of 6,786 feet, the pulse of the former beat 80, that of the latter 111 per minute.

In the year 1823, a French traveller, named Roulin, made some observations relative to the variations of the pulse, upon some men who for several months had been living at a height of 7,929 feet, upon the table-land of Santa Fe de Bogota. They were all of sound constitution, and aged respectively, 27, 26, and 23 years. On leaving Santa Fe, their pulses beat, in the above order, 69, 71, and 67 per minute; but upon descending into the plains, the pulse of each, so far from progressively diminishing in frequency, merely varied in an irregular manner, being sometimes even more frequent than at Santa Fe. The result, however, of Roulin's experiments, shows that as the atmospheric pressure between St. Martin and Santa Fe diminishes in the proportion of about 9 to 7, the average acceleration of the pulse between the same localities is as 6 to 7.

It would appear from the experiments of M. Roulin, that while the pulse becomes considerably accelerated at a great elevation, a protracted residence in such a locality has not the effect of maintaining this condition; but that, on the contrary, it ere long regains its natural frequency.

The same observer made another series of experiments upon three individuals, aged respectively twenty-eight, seven, and thirteen years. The two former had inhabited the plateau of Santa Fe for eighteen months previously.

The points of observation chosen by M. Roulin were Guaduas, 3,069 feet, and Santa Fe, 7,929 feet above the sea level; and the periods chosen were, first, the moment of awaking, the individual being in the recumbent position; and, secondly, the interval between the moment of rising and the morning meal—this observation being made in the upright posture.

Between these two stations, the mean of atmospheric pressure was found to be 0.78, and the average of the pulse at each locality shews that there exists no regular definite proportion between the increase of atmospheric pressure and the diminished frequency of the pulse.

In a memoir published by M. Le Pileur, to which I am indebted for much information on the subject in question, there are some excellent observations relative to the frequency of the pulse at great altitudes. These experiments were made during the ascent of the Mont Blanc, and from their accuracy of detail are well worthy of note. The tables containing the results of these experiments are here introduced, as affording at a glimpse a summary of the information thus acquired.

The opposite table contains a series of observations made upon the frequency of the pulse, at different heights, by different travellers.

Experiments upon the Frequency of Pulse at different Altitudes.

Locality.	Name of Observer.	Number of Pulsations per Minute.			Remarks.
Chamounix, 3650 ft. above sea level.	Saussure	Saussure 72	Balmat 49	Tetu 60	Four hours after arriving.
Summit of Mont Blanc, 14,760 Ft. feet above ditto.	ditto	100	98	112	Four hours after reaching the summit.
Col du Géant, 10,578	ditto	79 83			In the morning In the afternoon; recumbent. Ditto, upright.
Grand Plateau, 11,730 feet	Hamel	82 128			
Rochers Rouges, 13,800 feet	Clissold	Clissold 100 to 150			While in the act of ascending.
Pierre de l'Echelle, 7,008 feet	Sherwell	Sherwell 108	Guides 84 to 104		After eating.
Monte Rosa, 9,939 feet	Parrot	Parrot 110			
Noversch, 4,752 feet	ditto	80			
In the Plain . .	ditto	70			
Monte Rosa, 12,662 feet	Zumstein	Zumstein 76	Molindi 108	4 Guides, average 84	
Balloon Ascent, 7,806 feet	Biot	Biot 111	Gay Lussac 80		
Paris	ditto	79	62		

The following observations on the frequency of the pulse at different periods of the day and under various circumstances, were made by MM. Le Pileur and Martin at Paris, previous to their expedition to the Mont Blanc, with a view to establish a standard of its comparative frequency between the level of that city and the summit of the mountain.

Experiments on the frequency of the Pulse at Paris, by M. Martin.

LE GRAND PLATEAU ; 11,733 feet above the sea level.

July 31st	4-15	Slept the night previous on the Grands Mulets, arrived here this morning ; felt much indisposed, physically and morally ; posture horizontal : pulse barely perceptible	82 80 78	July 31st	4-0	Very little indisposition ; appetite tolerable ; tendency to sleep ; pulse moderately strong	100 98 98 100
Aug. 28th	3-0	Left Chamounix at midnight, arrived here at 11 A.M. ; posture horizontal.	83	Aug. 28th	2-0	Slight fatigue after cleaning the tent of snow ; observation made in the upright position.	100 104 102 102
29th	6-40	Observations made previous to rising.	78 80 81 84 80 84	29th	6-55	Slept well ; pulse feeble but regular.	88 86 86
30th	9-0	Gentle ascent for two hours before breakfast. Several alterations of position during the observation.	68 65 65 69 75 79 75 71 66 69 68	30th	7-50	Little sleep, having suffered from sciatica.	90 88 86 84 88
				30th	1-10	Took some food ; fatigue felt ; no mountain sickness while tranquil ; pulse moderately strong, not very compressible. Sitting posture.	78 80 84 80 82
Sept. 1st	7-15	Observation made in the recumbent posture.	74 70 67 67 66 67 68 67				
		Daily average	73-74			Daily average	90-80

SUMMIT OF MONT BLANC, 14,760 feet above the sea level.

Aug. 20th	4-0	Reached the summit at 1-45 P.M. ; during the first hour experienced nausea and vomiting ; pulse feeble	81 83 84	Aug. 29th	3-0	Observation made in the sitting posture ; pulse strong.	94 88 88 86 85
		Average	82-66			Average	88-20

It would appear from these tables that, after attaining a certain elevation, the frequency of the pulse is invariably increased. The level, however, at which this acceleration commences, evidently varies in different individuals; while in some, there is reason to believe that the influence of diminished atmospheric pressure may, within certain limits, be counterbalanced by concomitant circumstances capable of reducing the frequency of the pulse even while under such influences.

The pulse of M. Le Pileur was much less frequent at Chamounix than at Paris, although in the former locality there was everything in the approaching expedition calculated to produce nervous excitement. At Chamounix, it beat 60 per minute, and at Paris 67·25, notwithstanding the superior elevation of the valley.

In the case of M. Martin, on the contrary, the average frequency of the pulse was greater at Chamounix than at Paris, being 62·04 in the latter, and 69·00 in the former locality.

These same observers, having likewise made experiments upon the pulse of three guides who accompanied them to the summit, found the following differences in point of frequency between the level of the Valley of Chamounix and the highest point of the mountain :—

	Average of the pulse at Chamounix.	Do. at the summit.
Mugnier, aged 36	63·12	94·40
Coutet, " 34	77·75	117·83
Simon, " 27	69·22	111·06

It is worthy of note, that in these men, born among the Alps, the acceleration of the pulse was greater than in the case of MM. Le Pileur and Martin, who were habitually residing on a comparatively trifling elevation above the sea level, and but little accustomed to mountain air and exercise.

A *resumé* of the foregoing remarks may, I conceive, lead to the establishment of a few propositions relative to the affection which I have here designated by the term "mountain sickness".

1st. That in mountainous districts, and upon attaining a certain elevation, a series of physiological phenomena manifest themselves, which differ widely from the standard of health, and exist as long only as the exciting causes are in activity; disappearing upon a return to the ordinary level of human habitation.

2nd. That the discrepancy existing among travellers relative to these phenomena, is to be accounted for by their variability both in nature and degree; this variability being itself dependent upon conditions, referable on the one hand to the individual, and on the other to the locality.

3rd. That, on the part of the individual, the following circumstances may modify the nature and intensity of the "mountain sickness": idiosyncrasy, previous condition of health, the habit of fatigue (especially that produced by ascents), and previous residence in a rarefied atmosphere.

4th. That, as regards the locality, the phenomena in question are most strongly marked where a considerable elevation above the previous residence of the individual is attained in a short space of time; as on the Pass of the St. Bernard, the Col of the Mont Moro, and the Col de St. Theodule, in the Alps.

5th. That the mountain sickness is characterised by the following symptoms, the entire category of which, however, is seldom, if ever, united in one individual: vertigo, headache, somnolence, dyspnoea, constriction of the chest, palpitation, syncopal tendency, occasional oozing of blood from mucous surfaces, increased rapidity of pulse, anorexia, nausea and vomiting, thirst, febrile tongue, muscular pains, sense of extreme debility in the lower limbs, with general prostration of strength.

6th. That these symptoms may be referred to a threefold source, viz., a gradually increasing congestion of the deeper portions of the circulatory apparatus, increased vascosity of the blood, and loss of equilibrium between the pressure of

the external air and that of the gases existing within the intestines.

7th. That these exciting causes of mountain sickness are themselves the result of a change from a given atmospheric pressure and temperature, for one in which both are greatly and suddenly diminished.

Cheltenham, Nov. 24th, 1852.

ON INTERNAL UTERINE HÆMORRHAGE.

By GEORGE KING, Esq., Surgeon.

It may be remembered that I have drawn the attention of the readers of the former series of the *Provincial Medical and Surgical Journal* to the subject of internal uterine hæmorrhage, which seems to have escaped the notice of practitioners, as well as teachers and writers on obstetric practice; at least I have, like many others, searched in vain for information on this important subject, and for the records of such cases.*

The case reported in the number of the *ASSOCIATION MEDICAL JOURNAL*, for January 7th, as a "*peculiar case of accidental uterine hæmorrhage*," by Isaac Harrison, Esq., of Reading, was, I consider, one of internal uterine hæmorrhage. Being, I believe, the first who has directed the attention to this peculiar kind of uterine hæmorrhage, it is natural that such a case as Mr. Harrison's should attract my notice, and that I should make some remarks on it.

In directing attention to an occurrence which I consider has often till too late been neglected, internal uterine hæmorrhage during the period of gestation, I wish it particularly to be understood, that I do not mean to say that there is no external appearance or sanguineous discharge from the vagina: there often is in such cases; but it is so slight, and frequently at such lengthened intervals, that it passes unnoticed by both patient and doctor. This state of things goes on, until the patient herself begins to feel its debilitating effects on her constitution; and the practitioner is unconscious of the mischief going on, until his suspicion is excited by the constitutional symptoms. There is a universal paleness, which is first discovered in the face; the pulse becomes quicker and weaker; the abdomen is discovered to be much distended; the patient becomes restless and faint; her friends are anxious; and the *accoucheur* begins to see the danger, and feels his responsibility. All this may take place at almost any period of gestation, and without there being any external discharge. The danger does not so much depend on the quantity of blood lost, as it does on the velocity with which it is lost. In these cases, we cannot, by any means that I know, judge for a certainty either as to the quantity or velocity. All we know is, that frightful external hæmorrhage may occur; floodings may last for days; and even gushes of blood may be poured out from the vagina, without exciting much alarm for the safety of the patient; yet with even the slightest internal hæmorrhage, this insidious dripping within the cavity of the uterus may continue some time, and produce the most serious constitutional derangement, demanding the most prompt and energetic treatment, without our having any visible sign, or the slightest indication or knowledge of the cause, or the point from which it is emitted. We have yet to learn why the powers of nature should give way and often sink from such apparently trifling sanguineous discharges, and linger and survive a much more profuse one; and also why the uterus, a muscular substance, an organ only designed for the purpose of generation and the perfection of the fœtus (though it may be very vascular during gestation), should become a sponge to sop up the vital fluid of the mother as well as of the child, so that the life of both frequently is destroyed. As practitioners, we have to do with the symptoms, conse-

* I regret to find on referring to the index of the last volume of the *Provincial Medical and Surgical Journal*, that the word "internal" is left out in reference to the cases and treatment published by me.

quences, and treatment; and this is a very painful position to be placed in, as our resources are very limited, and the remedial measures are very few; and all those medicines which are called specifics in stopping hæmorrhage, are as futile as incantations. There is no medicine in the *Materia Medica* that can have a styptic effect in these cases; but we must do something, and all that can be done must be done mechanically, by removing the contents of the womb, or by external applications, employed as I have stated in another paper on this subject. The only means to be depended on as a remedy in these desperate cases, is cold water, a small hand, and the blunt hook. I have given directions for the application of cold water over the abdomen in such cases. If we can make the surface of the body contract, the internal parts will by sympathy contract likewise. Three out of four patients are lost in uterine hæmorrhage, mainly for want of being delivered when there was a possibility of delivering them, and a chance of saving their lives. The difficulty in such cases is not in what we ought to do, but when we should do it. I am not a disciple of the mystical German school, nor do I believe in the hydropathic method of treating diseases; but I do believe that in internal uterine hæmorrhage, the wet sheet may be very beneficially applied.

I have been led to these remarks by reading the case of accidental uterine hæmorrhage by Mr. Harrison, as the case published by me at p. 38 of No. 11, New Series, which I sent previously to the date of Mr. Harrison's paper, is so similar.

Mr. Harrison asks, "Could a more accurate diagnosis have been arrived at? and if so, could the treatment have been materially modified?" This would imply that he wished to have the opinion of others, and that he sought information on the subject, as to the diagnosis.

With such symptoms, it was natural to suppose that there was some great mischief going on within the walls of the abdomen; and, in the patient's condition, the uterus would be suspected to be the seat of the disease or disorder, and the existing cause ought to be removed; but how and when was this to be done? Without having seen the case, it is very difficult to say what ought to have been the treatment; and it may be considered presumptuous to say, that anything that was done ought not to have been done, or that anything was left undone that ought to have been done, as there might have been some peculiar idiosyncrasy of constitution, or many special circumstances, that could be only judged of by those who were present. Still, a remark or two on the general treatment of such cases may be useful to those who may be so unfortunate as to meet with similar cases in their practice.

After the rupture of the membranes, a full dose of the secale cornutum might, I think, have excited the contracting power of the uterus, and, by its stimulating quality, have kept up the failing powers. The mode of delivery I do not consider to have been the most safe and proper. The blunt hook would have been a much safer instrument, and more applicable than the perforator or forceps. As there was no propelling action of the uterus, and the head presented, there would have been no difficulty in introducing it, and of getting a good hold. The child, I suppose, was dead, and it would not have been of much consequence to what part we had fixed it. The chin, occiput, and mouth, were to be easily got at, and there appears to have been no rigidity of the os uteri, resistance, or want of repose. There was only a lack of physical power: this the blunt hook would have safely and easily supplied. The operation of craniotomy can never, in my opinion, be justifiable, unless there be a hydrocephalic head presenting, or an unusual degree of ossification of the entire bones of the cranium, or a very great degree of deformity and contraction of the pelvic orifice, or a dying patient. I believe it would not be considered orthodox to let a woman die undelivered. The powers of action in this case did not seem to have been exhausted, as she survived some hours after the loss of some quarts of fluid blood. Its being fluid is, I consider,

a clear proof that that was not the cause of the previous symptoms; but that the clots resulted from the internal hæmorrhage going on before delivery was attempted. We thus possess two means or ways of restraining uterine hæmorrhage; firstly, by exciting the power of contraction; and, secondly, by promoting the formation of coagula. Mrs. G. must have sunk from the loss of the quarts of fluid blood. I never lost a patient from hæmorrhage after delivery, who survived it an hour.

Bath, January 14th, 1853.

SUDDEN DEATH FROM COLLAPSE IN A CASE OF RUPTURE OF THE BLADDER.

BY ALEXANDER HENRY PATERSON, M.D.

CASE. January 15th, 1853, M. Corr, æt. 45, a labourer, was, at half-past eleven, P.M., slightly intoxicated, and engaged in a quarrel with another man. On receiving a blow on the chest, he fell, but appeared not much hurt. He was separated from his antagonist, and walked a short distance. The two men then met, and renewed their dispute; and collaring each other, rolled down together, Corr falling on his back, and his antagonist upon him. As Corr was rising, his antagonist, who had regained his feet, ran towards him, and kicked him in the lower part of the abdomen. The blow was the more violent as the man had wooden clogs on. Corr fell back, and died immediately.

On making a *post mortem* examination, on the 17th, I found the brain healthy, though congested; the heart was free from disease, but much distended with black, feebly coagulated blood. The abdomen appeared healthy, and free from all injury. On scratching aside the peritoneum from the pelvis, my finger passed into the bladder, through a rent almost two inches in length. There was some bloody urine, perhaps an ounce, effused into the cellular tissue. The injury occurred on the left side of the body of the bladder. That organ and the urethra were healthy, and the peritoneum was uninjured. The body did not exhibit any internal marks of violence.

REMARKS. I have not met, either in Beck's or Taylor's Jurisprudence, with a similar case; and though I have seen several fatal instances of laceration of the bladder, death has not occurred for some hours or days.

It appears to me clear, that in this case death resulted from the shock to the sympathetic system; and that the rupture of the bladder had nothing to do with it. The darkness and fluidity of the blood, and the congested state of the brain, lungs, and especially of the heart, all confirm this view.

Altrincham, Cheshire, January 1853.

BIBLIOGRAPHICAL NOTICES.

A TREATISE ON TUBERCULOSIS, THE CONSTITUTIONAL ORIGIN OF CONSUMPTION AND SCAFULA. By HENRY ANCELL, late Surgeon to the Western General Dispensary, etc. pp. 778. London: 1852.

THE object of this very able and elaborate work is to draw attention to that state of the constitution which is characterised by the term *tuberculosis*, and on which Mr. ANCELL is satisfied that *scrofula* and *consumption*, in all their varied manifestations, depend.

"Tuberculosis is herein regarded, strictly, as a blood disease. I have endeavoured to collect all the most important facts relating to the physical and chemical properties of the blood, the aberrations observed in the phenomena of cell-growth and nutrition, the histology of tubercular deposits, and the special pathological anatomy of the tissues and organs, and have referred them to the primary affection as sequences, or results. Those maladies which are but local manifestations of the same

bid condition of the blood, as phthisis, hydrocephalus, hydrarthrus, and scrofulous caries, are thus exhibited according to their natural relations, but in a novel and more connected manner: and the whole subject is treated upon an original plan." (Preface, pp. 9-10.)

The work is divided into Eight Chapters.

Chapter I treats of the Tuberculous Predisposition. Under this head are noticed, in succession, the state of the blood, physically, microscopically, and chemically; the state of the fluids which supply the blood—lymph and chyle; the blastema; structural characteristics, as exhibited in the various tissues and organs of the body; functional characteristics, as shown in the digestive, respiratory, circulatory, secretory, excretory, and animal and nervous functions; and the concluding section of this chapter exhibits a general summary of the state of the constitution in the tuberculous predisposition. The facts show, that in tuberculosis there is a disturbance in the development, and an irregularity in the form of different parts of the body, particularly of those which have cell-growth for their basis: but the whole, or even the majority, of these peculiarities, are by no means always present; but few may be observed, and none can be said to be constant.

"From all that has preceded, the tuberculous predisposition is not a mere aptitude to be more easily affected by the causes of tuberculosis. Short of internal disease, it is an abnormal state of the constitution, both in its solid and fluid constituents, and in its vital power, of the same nature as tuberculosis. Where the predisposition ends, and where tuberculosis as a disease begins, it is most difficult, if not impossible, to determine. Nor does the predisposition necessarily pass into disease. Many have been deemed consumptive throughout life, from having exhibited this constitution in a well-marked form, and have nevertheless attained longevity, and died from some other malady. It by no means follows from this circumstance, that their blood was never tuberculous, and that they were never subjects of the predisposition: but it shews that, under favourable circumstances, the predisposition may never pass into actual disease, and that the blood has either been in a tuberculous state in a slight degree only, or, if more intensely affected during the period of growth and development, that it has recovered the standard of health at a later period of life. Even the conformation of the osseous skeleton, as of the bones of the chest, will improve if the constitution of the blood be improved; a circumstance which has been occasionally observed to happen without obvious cause. Again, tuberculosis may attack not only individuals of this particular habit, but even the robust, with a complete physical development, well formed chest, and great muscular power." (pp. 58-9).

In Chapter II, we find an exposition of the Signs and Symptoms of Tuberculosis. The subjects here discussed are *anæmia*, which is one of the earliest symptoms; atrophy, one of the most general structural changes; direct debility of the various organs and functions; diminution of the power of sustaining animal heat; and febricula. In his general summary at the end of the chapter, Mr. Ancell refers all these states to the morbid condition of the blood, which is deficient in vitality, with defect of red corpuscles and vitiated liquor sanguinis. He believes the phenomena of the predisposition to the disease, and its symptoms, to show—

"1. That from the earliest invasion, the sum of the vital forces is either below the standard of health, or it is relatively low as respects the structure and organisation of the individual.

"2. That this diminution in the sum of the vital force depends especially upon diminished vitality of the blood and of the cellular, gelatinous, and muscular tissues produced and nourished from an imperfect blastema derived from the diseased blood.

"3. That, as tuberculosis advances, the sum of the vital force for the whole system continues to diminish; this loss of vital force being exhibited not only in the defective manifestation of voluntary and involuntary muscular powers, but in the diminished resistance of the vital powers of the blood, and of the cellular and muscular tissues to the change of matter in the animal body: hence, in tuberculous subjects, the rapid diminution of the red corpuscles of the blood, the deterioration of the vital qualities of the liquor sanguinis and of the blastema, the

diminished plastic power of the cells, the low calorific power, and the emaciation.

"4. That frequently, but by no means universally, the nutritive powers of the blood, as respects the nervous tissue, remain undiminished, this tissue not requiring for its nutrition compound principles identical with itself to be introduced into the blood with the food, and having a nutrition peculiar to itself. Hence the diminution of vital force is not exhibited in the nervous system, but, as the conductor of the force generated by the change of matter in the whole system, the nervous system remains intact. The particular condition of the vital force is, nevertheless, manifested through the nerves; hence activity and action without power, morbid irritability, etc." (pp. 109-10).

Chapter III is devoted to an examination of Tuberculous Deposits; under which head are included tuberculous or scrofulous pus; more solid deposits, including cicatrices; tubercle, the history and pathology of which is very ably given, and which the author believes to be without doubt a substance *sui generis*; and melanotic matter.

In Chapter IV, Mr. Ancell enters very fully into the subject of the Special Pathological Anatomy of Tuberculosis. The forms under which tubercle is developed in each organ and system of organs in the body, are elaborately but clearly described; and the chapter is concluded by some general observations and deductions from the facts developed. Among these deductions, we find the identity of tuberculous and scrofulous affections again impressed on our attention.

Chapter V treats of the Causes of Tuberculosis. The author first makes some remarks on the imperfect nature of our statistics of the disease, showing that the absolute frequency of tuberculosis is by no means determined by the statistics of the mortality of its most aggravated and fatal forms. Hereditary transmission, and the various predisposing and inducing causes of tuberculosis, are very fully examined, in a manner which renders it impossible for us to do justice to the author by attempting to give an abstract. There is a highly instructive section on the influence of climate, on which subject the author's views appear to agree very closely with those of Dr. Burgess, as developed in his work on the *Climate of Italy*. In the summary at the end of the chapter, we find the following remark:—

"The true cause of the disease is still unknown. There are certain external agencies which, in the present state of physical science, it would be unphilosophical to overlook, while it is impossible to assign the relation they bear to the etiology, such as the abstraction of the genial influence of the solar rays, and the operation of the forces of electricity and magnetism; and it is necessary, in continuation of the inquiry, to bear in mind the laws of electro-physiology, the magnetic properties of oxygen gas, the correlation of the physical forces as respects each other, and the correlation of the physical and vital forces." (p. 347).

In Chapter VI, we find an examination of the Essential Nature and General Pathology of Tuberculosis. Mr. Ancell first gives a brief view of the numerous theories which have been propounded with regard to this subject, from Hippocrates down to the writers of the present day. He then describes more fully the following doctrines:—

1. Theories of tuberculosis, in which the disease is referred to some error in primary digestion: (*a*) generation of an acid in the primæ viæ (Mr. Carmichael); (*b*) plethora of the vena portæ in its roots and branches (Dr. Todd); imperfect development of the chyle and lymph granule (Professor Schultz).

2. Theories referring tuberculosis to a special morbid condition of the lymph (Charmetton, White, Baumes, C. Hufeland, J. Simon, etc.).

3. Theory of defective respiration imperfectly replaced by the liver (M. Luigi Parola).

4. Theory of the essential inflammatory nature of tuberculosis.

5. Theory of debility of the organic nervous power (Dr. Copland).

6. Theory of a poison in the blood (Dr. W. H. Madden).

7. Theory of malnutrition: (*a*) vitiation of the blood in the process of respiration (M. Baudelocque); (*b*) disturb-

ance of the healthy relations of the oily and albuminous principles, and an excess of the latter (Dr. Hughes Bennett); (c) retrograde morphology (Dr. W. Addison).

Mr. Ancell "has no hesitation in declaring his opinion, that Dr. Hughes Bennett has advanced furthest in the investigation of the real nature of the disease".

Two instructive sections on the diagnosis and prognosis of tuberculosis follow; and the author then comments on the relation of tuberculosis to other blood-diseases: viz., scorbutus, cancer, gout, diabetes, granular disease of the kidney, cyanosis, typhus and typhoid fevers, and intermittent fever. The relation of tuberculosis to the last-named disease is very carefully examined, and the opinions of the various writers on the subject compared; and Mr. Ancell arrives at the following conclusions, which we transcribe, leaving it to our readers to determine how far they are in accordance with what they have been able to observe:

"1. The morbid condition of the blood produced by the malaria or poison of intermittent fever, is totally distinct from the morbid condition of the blood which attends tuberculosis.

"2. The intense and permanent poisoning of the blood by malaria renders it insusceptible of the morbid condition which constitutes tuberculosis.

"3. A slight degree of poisoning with malaria, or the casual occurrence of intermittent fever, does not render the blood insusceptible of tuberculosis; and its degree of insusceptibility bears some relation to the degree of impaludation.

"4. Individuals affected with tuberculosis in a high degree, either with or without the manifestation of local disease, are not cured by residing in a malarious district.

"5. The blood of individuals poisoned by malaria, recovers from the effects of the noxious influence after removal from the malarious atmosphere; and then, however complete the insusceptibility to tuberculous disease may hitherto have been, the susceptibility returns, and tuberculosis actually occurs on exposure to the inducing causes.

"6. In accordance with the position laid down at (4); individuals so acquiring tuberculosis are not cured by a return to a malarious atmosphere.

"7. In Great Britain, and many other countries, where complete impaludation of any very extensive district is not now likely to occur, it is not probable that the antagonistic influence of the paludal poison will exert any great effect on the amount of tuberculosis occurring in any district.

"8. It is probable that the fevers known as intermittent, remittent, or continued, occurring in different countries, have their origin in different kinds of poison introduced into the blood, some of which may produce antagonistic effects, and some not.

"9. The beneficial effects, as far as a tuberculous state of the blood is concerned, of a residence in a malarious atmosphere before the manifestation of local disease, or in its incipient stages, is highly probable; but, looking to this effect on the medical statistics of large numbers of individuals, as of troops serving at malarious stations, it cannot be held that the human race would gain anything by poisoning the blood with malaria to a sufficient extent to cure tuberculosis." (pp. 615-16).

In Chapter VII, Mr. Ancell treats of the Forms and Varieties of Tuberculosis; and in Chapter VIII, he gives an elaborate view of the Treatment of Tuberculosis. The indications of prophylactic and curative treatment are—

"1. To prevent the hereditary transmission of the disease.

"2. To prevent, in the propagation of the species, the production of the disease, or of those states of the constitution which act as predisposing causes.

"3. To prevent the development of the disease in the fetus.

"4. To correct the predisposition, and to prevent the development of the disease after birth.

"5. To cure the tuberculosis, and thereby to prevent the deposition of tubercles, or to render them innocuous when deposited." (p. 655).

We had hoped to give an analysis of some of the instructive remarks made by the author in this chapter; but find that we must be content with heartily recommending it, as containing valuable precepts.

We have thus attempted to give a slight sketch of a work which is truly a luminous encyclopædia of the subject of which it treats. It exhibits the marks of profound medico-

historical research; and contains the opinions, in a well digested form, of nearly every accessible author who has written on consumption and scrofula, from Hippocrates downwards. Mr. Ancell combines and compares these opinions, and deduces from them his own conclusions; hence the great principle which he seeks to prove, is never lost sight of—that tuberculosis is the common constitutional origin of consumption and scrofula, and is a blood-disease.

HOUSEHOLD CHEMISTRY; or, Rudiments of the Science applied to Every-Day Life. By ALBERT J. BERNAYS, F.C.S., Lecturer on Chemistry, Derby. New edition. 12mo. pp. 276. London: 1853.

THE practical turn given to chemical studies in the present day is very apparent; and in nothing is this more apparent than in the application of the rigid principles of the science to the elucidation of the phenomena of the kitchen and the dining-room. Liebig opened the way in this direction in his *Familiar Letters on Chemistry*, in which are recorded facts and principles, divested, to a great extent, of the uninviting aspect of a dry, technical nomenclature. The author of the work before us follows in the same path, and usefully and simply unfolds the theory and practice of Household Chemistry, which ought to be better understood than it now is. The work is essentially popular, and is neither intended for medical men nor for scientific chemists; but it is precisely such a book as we have often desired to put into the hands of intelligent patients, when we have wished them to comprehend, a little better than we could explain in a hasty conversation, some of the reasons for our dietetic prescriptions and cautions. We subjoin a short extract, as a specimen of the author's style and matter.

"The best method of BOILING MEAT intended for food is to introduce it into *boiling water*; if the boiling be kept up for five minutes, and then so much cold water added as to reduce the temperature to 165°, and the whole kept at this temperature for some hours, all the conditions are united, which give the flesh the quality best adapted for its use as food. When it is introduced into the boiling water, the albumen immediately coagulates from the surface inwards, and in this state forms a crust, which no longer permits the external water to penetrate into the interior of the mass of flesh. But the temperature is gradually transmitted to the interior, and there effects the conversion of the raw flesh into the state of boiled. The flesh retains its juiciness, and is quite as agreeable to the taste as it can be made by roasting. When the temperature of the interior of a piece of meat has not reached 144°, it presents a blood-coloured or underdone appearance.

"The flesh of poultry is sooner done than meat, because it contains little blood, and therefore requires a lower temperature.

"The use of lard in roasting is to prevent the extraction of the tasty constituents from the flesh by its juices, and evaporation of the water, which causes hardening.

"Now, although the introduction of the raw meat into boiling water is the best process for dressing it, it is the worst for obtaining soup. If the raw meat be placed in cold water, and this brought very gradually to the boiling point, there occurs, from the first moment, an interchange between the juices of the flesh and the external water. The flesh loses, while the soup gains in sapid principles, and extracts both lactic and phosphoric acids,—two most important constituents of the gastric juice.

"The best method of preparing so-called beef-tea, is to take finely-chopped raw beef, to mix it with its own weight of cold water, and, after the lapse of about three minutes, to heat it slowly to boiling. It should be allowed to boil for two or three minutes, and should then be strained through a cloth; when an equal weight of the most delicious and strong beef-tea (such as cannot be obtained by boiling for many hours), is at once obtained. When properly seasoned, it forms the very best soup that can be made.

"It has long been customary to ascribe to the gelatinous matter dissolved during boiling, which gives to concentrated soup the property of forming a jelly, the chief properties or peculiarities of the soup; but Liebig has shown that the

mistaken notion. The simplest experiments prove that the amount of dissolved gelatine in well-prepared soup is so small, that it cannot come into calculation in explaining its nutritive properties. Gelatine (isinglass is pure, glue impure gelatine) is, in itself, quite tasteless, and consequently the taste of the soup cannot be derived from it. Boiling water, when allowed to act for five hours on finely-chopped flesh, does not dissolve more than the fifth part of the matter soluble in cold water, even after the albumen has been separated by heating the cold infusion; and this fifth part, besides, does not consist of pure gelatine, but contains all the products dissolved out of the muscular fibre by long boiling.

"It is equally customary to ascribe great strength to dark-coloured soups. A little burnt sugar (caramel) or burnt onion, will give depth of colour to the beef-tea prepared after the above prescription."

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

PASTE MADE WITH SULPHURIC ACID AND SAFFRON AS A NEW CAUSTIC IN MALIGNANT ULCERATION OF THE FACE.

M. E. CAZENAVE, of Pau, relates, in *L'Union Médicale* for 22nd January, two cases of malignant ulceration of the face, in which he has successfully employed a local application, made from sulphuric acid and powdered saffron. The remedy is formed by pouring the acid on the saffron, and applying it in the form of a soft paste. Its corrosive action is immediately manifested on the diseased tissues: the paste dries, and falls off in two or three days, in the form of black crusts, which carry with them the eschar. The application is made several times: the wound assumes a healthy red tint, and cicatrization takes place. In one case, a year has elapsed, and in the other two years; and the disease has not returned.

The efficacy of this treatment is evidently dependent on the sulphuric acid; which, we believe, would succeed equally well if made into a paste with common flour, or any ligneous powder, as with saffron. A paste of sulphuric acid and flour would be worth trying in obstinate cases of phagedenic ulceration.

ELECTRIFIED OXYGEN, OR OZONE, IN THE TREATMENT OF ALBUMINURIA.

At the meeting of the Academy of Sciences in Paris, on January 17, M. ROBIN made a communication, with the view of showing that electrified oxygen, or ozone, mixed with air, might be of advantage in the treatment of albuminuria, by favouring combustion.

The author said that, at the time when his researches, and those of others, showed the extreme importance of slow combustion in the maintenance of the vital phenomena, other experiments had pointed out ozone as much more appropriate for maintaining combustion, than oxygen obtained by the ordinary chemical processes. Hence ozone, either pure, or mixed with air, would be a valuable agent in cases of asphyxia, in scrofula, in cases of poisoning in general, and in all circumstances where it is either desired to support the powers, or to stimulate combustion when reduced below its normal standard, or especially as a reanimating agent in cases where air and ordinary oxygen are found of no service.

Electrified oxygen is easily obtained, by the decomposition of water by the galvanic pile. It may be mixed with air, by causing a current to flow into the tube through which the oxygen is inhaled.

Two birds were rendered insensible; one was then introduced into ordinary oxygen, the other into pure ozone. The one which was introduced into the ozone recovered more rapidly, but manifested much agitation; while the other recovered quietly.

FOWLER'S SOLUTION OF ARSENIC IN CHOLERA.

Dr. O. SAEMANN, in the *Deutsche Klinik* for October 30, 1852, states that the observation that, in cases of pernicious intermittent fever, arsenic has been found of great service, led him to imagine that it might also be useful in cholera. He had no opportunity himself of giving this medicine; but Professor Burow, to whom he communicated his views, gave to twenty-

nine cholera patients, doses of four drops of the arsenical solution every hour or half-hour; and only one of them died. It is to be observed, however, that Dr. Burow also gave valerian, nux vomica, and opium, and sometimes also quinine.

Dr. Saemann thinks the subject worthy of further investigation. It must, however, be fairly tested by using the medicine as much as possible *per se*.

SURGERY.

ENTRANCE OF AIR INTO THE SUBCLAVIAN VEIN: APPARENT RECOVERY: DEATH IN THIRTEEN HOURS.

M. A. GIRBAL relates the following case in the *Gazette Médicale de Paris*, for January 22. It affords a good example of those cases in which death takes place from secondary causes, and not from the mere mechanical distension of the right side of the heart.

CASE. On June 20, 1850, he assisted Dr. Bertrand at Tarascon, (Bouches du-Rhone), in removing a scirrhus tumour from the neck and upper part of the chest of a gentleman, fifty years of age. Chloroform was administered, the tumour was removed, and the vessels were tied.

The operator, observing a small portion of diseased tissue behind the clavicle, endeavoured to detach it with the handle of his scalpel. It was removed without any traction; when a sudden flow of venous blood took place from the spot, and there was at the same time heard an acute and prolonged whistling sound. The patient was not at the time under the influence of chloroform. His face instantly became colourless, his countenance changed, and he uttered a slight plaintive cry. His extremities became cold; the pulse could not be felt; and the chest was covered with a cold sweat. Intelligence, speech, sensation, and motion were entirely lost. On examination of the heart, M. Girbal heard for about a minute a sound of *gargouillement*, distinctly masking the natural sounds. The resonance of that part was notably exaggerated. These symptoms continued three or four minutes; during which time, M. Bertrand compressed the opened vein by means of a sponge. The chest and limbs were rubbed; and alcohol and ether were held to the patient's nostrils. The syncope having closed, the sponge was left in its place, with some pieces of amadou on it, and the wound was dressed. In an hour, the pulse was almost normal, the heat of the body natural, the breathing free, speech easy; and the heart and lungs apparently healthy. This satisfactory state continued for thirteen hours, when the patient was suddenly seized, during the night, with dyspnoea, oppression, heat of the head, and redness of the face; and he died in an hour.

TUBERCULAR DISEASE OF THE VERTEBRÆ DIAGNOSED BY PERCUSSION.

Tubercular disease of the spinal column often causes sufficiently obvious external signs; but sometimes the swelling of the bones lies internally, causing no visible projection, and the only marked symptom is weakness, gradually amounting to paralysis, in the lower limbs. In such cases as these, M. Piorry, (*L'Union Médicale*, January 20, 1853), believes that he can form a diagnosis by means of percussion. This is performed with the patient placed in the prone posture, with a pillow under the abdomen. In this way, the situation and limits of the swelling can, according to M. Piorry, be accurately defined; and some cases are related, in which the nature of the affection under which the patients laboured, was thus diagnosed.

With M. Piorry, as is well known, percussion is the great means of diagnosis; but, while we allow that this is a valuable aid, we think that he rides his hobby a little too hard; and that the attempt to keep pace with him would end in a terrible downfall. In saying this we do not wish to discourage our readers, if they have sufficient power of appreciating sounds, from employing M. Piorry's plan in cases where they feel that their usual guides in diagnosis fail to aid them.

The treatment used by M. Piorry consists of rest, principally in the horizontal posture; avoidance of a long continuance in the erect position; nourishing diet, good wine, pure air, and light; iodide of potassium; and phosphate of lime internally. He has great faith in the phosphate of lime, on account of its being deficient in the bones. We are, however, disposed to ascribe any favourable results to the hygienic treatment and the iodide of potassium.

DISEASES OF CHILDREN.

CASE OF EXTENSIVE VISCERAL INFLAMMATION,
AND APOPLECTIC EFFUSION, OCCURRING IN
A FÆTUS IN UTERO.

In the *Deutsche Klinik* for November 27th, Dr. C. Hüter, of Marburg, after referring to several authors who have written on the subject of intra-uterine inflammation occurring in the fœtus, relates the following case, which we abridge.

CASE. U. M. H., aged 28, of small, weak conformation, was delivered, on March 28, 1852, after a tolerably easy labour, of a female child, apparently of the full period. It was apparently dead; but gasped several times while attempts to resuscitate it were carried on. These attempts, however, proved quite unsuccessful.

Post mortem Examination. Much blood escaped on making an incision into the back, and also from the vertebral canal. Beneath the dura mater, in the neighbourhood of the cauda equina, there was a clot of the size of a pea, and a larger one near the foramen magnum. The medulla oblongata was surrounded by coagula. A quantity of blood flowed from the vessels of the arachnoid, especially near the cauda equina. Between the skin and the galea aponeurotica, the whole skull, as far as the cheeks, was covered with a gelatinous effusion, here and there containing extravasated blood; and there was a general excess of blood in these parts. The cerebellum was surrounded with coagulated blood; and between it and the tentorium, were numerous small clots: blood was also extravasated in the tentorium itself. Within the cerebellum, there were six coagula, each of the size of a pea. The cerebrum was also very full of blood, and contained several extravasations. On the right side of the longitudinal sinus, there was a coagulum in the form of a leech. In the right choroid plexus, a varicose vessel was found. In the vicinity of the lateral ventricles, there was so much blood effused, that the cerebral mass could not be distinguished.

On opening the chest, much gelatinous exudation was found under the skin; but there was no serum in the pleura. The thoracic viscera, taken together, swam in water; the right lung swam in water, the lower lobe tending to sink; the left lung sank to the bottom of the vessel. The bronchial tubes in the right lung yielded some frothy mucus on pressure; those of the left less. The upper lobe of the right lung was firm to the touch, crepitated on incision, and yielded greyish frothy matter, but little blood: when it was incised under water, small bubbles of air escaped. The lower lobe was firm, crepitated less, but yielded frothy mucus on pressure. On section, white firm spots were found in this lung. The left lung felt firmer, and knotty, and was mostly non-crepitant. In the vicinity of the lower surface of the upper lobe, and the upper part of the lower lobe, it crepitated a little, and contained a little air.

There was not any increased quantity of fluid in the pericardium. The cavities of the heart contained firmly coagulated blood, which extended into all the openings, even through the foramen ovale, and adhered firmly to the walls of the organ. Some of the trabeculae in the right side of the heart were of a yellowish grey colour, and hard. On cutting through the septum, it was found to have degenerated into a yellow hard mass, from about three lines from the apex as far as the auricles, for a breadth of three or four lines. In the midst of this degenerated portion was found a cavity the size of a pea, from which purulent fluid escaped on incision; and nearer the apex there was a smaller cavity. On microscopic examination, pus corpuscles were observed.

Between the abdominal muscles and the abdomen, were found gelatinous masses. The umbilical vessels contained no blood. The intestines were glued to each other, and to the peritoneum, by plastic exudation. The peritoneal cavity contained a large quantity of serum. The large intestine was thickened, and contained much meconium. The small intestines contained thin, mucus-like masses. The mucous membrane was easily separated. The liver and spleen were very sanguineous. The right Fallopian tube was cemented by exudation matter with the small intestines, but was not itself inflamed. The muscles of the limbs were pale.

The mother was discharged well on the 8th April.

EDITOR'S LETTER BOX.

ON THE CASE OF POISONING BY ACONITE, AND
THE INQUEST AT THE CONVENT OF THE
GOOD SHEPHERD.

LETTER FROM DR. O'BRYEN TO THE EDITOR.

SIR,—As few complete cases of poisoning by tincture of aconite are on record, may I beg insertion in the *ASSOCIATION JOURNAL* of the following remarks, in addition to, and in explanation of, the account of the inquest which appeared in the number of last Friday, p. 71. The conduct of the jury and of the coroner were so unusual as to claim attention from the profession.

I was requested, on the 5th of this month, to visit some patients at Arno's Court, near Bristol, an establishment for the reformation of unfortunate females. Two were suffering from severe neuralgia of the face, and one (the individual whose case I am about to describe) complained of tape-worm, with which she had been afflicted for some years. I ordered her to take one drachm of the bark of the root of pomegranate, and one grain of quinine in water, every morning, fasting; and, after a week, to take half an ounce each of spirit of turpentine and castor oil, also in the morning. I directed for the other two proper diet, a mild aperient, and thirty drops of the following embrocation, to be applied externally over the seat of pain:—Tinct. aconiti (Flem.) ʒss; acet. morphiae gr. iv.; to be marked. "The embrocation for external use only; a piece of linen, the size of half a crown, to be wetted with thirty drops, and applied over the seat of pain, covered with oil-silk, and a bandage." Unfortunately, at 7½ o'clock, A.M., on the 10th inst., the pomegranate being prepared in water, and placed in a bottle next to the embrocation, the lady who undertook to administer it, poured, by mistake, rather more than a teaspoonful of the embrocation into a cup, and then half filled it with water, and gave it to E. Forty; who drank it at once, and in a few minutes became very thirsty, and complained of a great burning and pain in her stomach and throat, and drank two tumblers of cold water, and in fifteen minutes began to vomit violently, which she continued to do for two hours. At first, she stood up to vomit; on a second attempt, she fell back in the arms of an attendant, helpless as if dead. She was very restless; the pain in the epigastric region increased. After the first hour, she was unable to do more than turn her neck and head a little, and to vomit. She now had tenesmus and convulsive movements of the muscles. At nine o'clock, she began to look stupid, complained of vertigo, and was covered with cold sweats. At ten o'clock she was quiet as if asleep; at a quarter to eleven she was still conscious, replied to questions, and said, "Lord, have mercy on me"; she then apparently went to sleep, and was not discovered to be dead until half-past eleven o'clock, A.M. There were no general convulsions observed. Pain in the epigastric region was very marked up to the last.

Jan. 14th. My friend Mr. Prichard made the *post mortem* examination with me. We found the face looking swollen and dark-coloured, as well as the lips; the muscular system rigid; the pupils rather dilated; the eyes very bright. The expression of the countenance was that of a person who had died a violent death. The membranes of the brain were congested, but the brain itself firm and healthy. The lungs were also healthy, with some *post mortem* congestion from gravitation; when the thorax was opened, they did not fill the cavity. The heart was flaccid, and the walls of the ventricles were rather thin. The uterus was rather congested; the bladder empty; the sphincter ani was relaxed, and the anus very open. The stomach contained some mucus, and the membrane lining the large curvature was injected in patches, but otherwise natural. The abdomen contained thickened mucus, and the mucous membrane was in a high state of inflammation, abraded in patches; the membrane being in them dissolved and broken down. There were many spots of a very dark colour. The small intestines contained a large tape-worm, many yards long.

As I did not see the patient whilst suffering under the effects of the aconite, I have collated these symptoms from the very imperfect information of non-medical persons: pain in epigastric region, thirst, vomiting, vertigo, muscular prostration (as evidenced by her inability to stand), cold sweats, irregular convulsive movements of the muscles, some stupor of the countenance two hours after the dose was swallowed; in three hours, apparent sleep, but consciousness and speech to within half an hour of death. The state of the abdomen shows well the

irritant action of the poison. The grain of acetab morphine the deceased took with the aconite, neither appeared to produce sleep nor stop the pain.

I was summoned by the coroner to attend as a medical witness at the inquest, the deceased *having been attended by me* a few days before her death.

The conduct of the jury and coroner in this case deserves a few remarks. When the jury met at Arno's Court to view the body, they directed it to be undressed for them to examine it. The coroner informed me that *the jury could not permit me to be present, as they desired to make remarks they did not wish me to hear*. One of the jury insisted on taking the case out of my hands, and on nominating another surgeon to make the *post mortem* examination, without any reference to me. This gentleman the jury had agreed to appoint; but I declined to meet him under the circumstances, and intimated that I would retire at once. Such conduct appeared to me to be in contravention of the Medical Witnesses Act, 6 & 7 of William IV, c. 89, 1st clause, to which I beg to refer. After some discussion, my friend Mr. Prichard was ordered by the jury to make the post-mortem examination, and I was requested to assist. In the third place, I was ordered to leave the court during the *whole time the witnesses were examined*, without reason assigned, against which I protested, but in vain.

The effect of the jury taking the place of the medical witnesses in examining the body for themselves, was, that two spots of commencing decomposition on the abdomen were taken by them for marks of violence, and insisted on, even against my positive evidence to the contrary; and they apparently yielded when Mr. Prichard demonstrated the absence of the effects of violence in the tissues, and otherwise corroborated my statement. I say apparently, for Miss Ryder was recalled, and sworn to the fact, that no violence had been used to the deceased.

What shall I say of the exclusion of the medical witness from the court?—*a hitherto unheard-of proceeding*. I was thus prevented from hearing and judging of the facts of the case which might come out in evidence, and which, in most cases, would materially assist in deducing just conclusions. I had, however, taken care to examine all the witnesses myself, and had quite made up my mind that Emma Forty had died from the effects of about seventy drops of Fleming's tincture of aconite, given by mistake.

JOHN O'BRYEN, M.D.,

Physician to St. Peter's Hospital, Bristol.

Clifton, Bristol, January, 1853.

[We intend in an early number to draw attention to Coroners and their Inquests.]

PETITION TO PARLIAMENT AGAINST THE INCOME-TAX, FROM THE MEDICAL PROFESSION IN TORQUAY.

LETTER FROM DR. NANKIVELL TO THE EDITOR.

SIR,—The enclosed petition has been signed by all the medical men practising in Torquay; and at a meeting of the Medical Society, Dr. BATTERSBY and myself were deputed to forward it to Sir J. B. YARDE BULLER, one of the members for South Devon, and to request him to present it to the House of Commons; but, as Parliament had adjourned to the 10th Feb., when it is most probable the budget will have been decided upon by the Ministry, Sir J. B. YARDE BULLER was requested to suggest some mode, by which the petition might be laid before the Chancellor of the Exchequer earlier than the meeting of Parliament. In compliance with this request, he has kindly recommended the following plan:—

"Have a copy made of the petition and its signatures, with a note to the Chancellor of the Exchequer, telling him that a petition, of which that is a copy, has been placed in my hands for presentation to the House of Commons; and respectfully call his attention to it. These two documents I will forward to the Chancellor of the Exchequer; and in this way, I think, your object will be attained."

Our professional brethren here, I have no doubt, in common with all members of the profession throughout the country, think and feel the income-tax to be a great and grievous injustice to them; and they have considered it especially important at the present moment, to raise their voices against its re-enactment in its existing form, from the fact, that the Chancellor of the Exchequer has expressed an opinion against any alteration in its adjustment, though he states that the subject is open to further consideration. They likewise hope that you will have the kindness to insert their petition in our ASSOCIATION JOURNAL, as the surest means of bringing the subject before the

profession at large; and of inducing our brethren in all the large towns throughout the kingdom, to send similar petitions to the House of Commons, and in this way express the united voice of the profession against the continuance of a heavy burden and a flagrant injustice, which they have hitherto borne with too much patience.

I am, sir, your obedient servant,

C. B. NANKIVELL, M.D.

Torquay, Jan. 19th, 1853.

"The Humble Petition of the undersigned members of the medical profession, practising in Torquay and St. Mary Church:—

"This petition sheweth,—That your petitioners only derive from their professional exertions most uncertain and precarious incomes, and which of necessity cease under impaired health, in advanced life, and at death.

"That your petitioners are, for the most part, married men, with families, for whose education and present and future support, under the contingencies of illness, advanced age, and death, they have to provide by these uncertain and precarious incomes.

"That your petitioners feel it a great grievance, and cannot but consider it most unjust, that their professional incomes, thus precarious, should be taxed at the same rate as incomes derived from realized property, which are not affected by the health or age of the possessors, and which descend to their families after their death.

"Your petitioners, therefore, humbly pray that, in re-imposing the Property and Income Tax, your honourable House will so alter its adjustment as to press less grievously upon them, in common with all others alike depending upon temporary and life incomes.

"And your petitioners will ever pray," etc.

PARLIAMENTARY REPRESENTATION OF THE UNIVERSITY OF LONDON.

LETTER FROM DR. SNOW BECK, SECRETARY TO THE FRANCHISE COMMITTEE OF THE GRADUATES OF THE UNIVERSITY OF LONDON, TO THE EDITOR.

SIR,—In a recent number of the Journal (Jan. 7th), a letter appeared from Mr. Allen, Secretary to the York School of Medicine, in which we are informed, that "at a meeting of the lecturers of the York School of Medicine, the representation of the University of London in Parliament was thought highly desirable, inasmuch as the medical profession might thereby obtain a more direct voice in public affairs." The lecturers also inquire, "the opinions and intentions of the Committee of Graduates, as to whether the franchise should be conferred on the teachers of the Provincial Schools, irrespectively of their being graduates of the University."

When, in the autumn of last year, it was considered advisable to take active steps for procuring representatives in Parliament for the University of London, a "Franchise Committee" was formed at the public meeting of the 30th December, consisting of the principals and professors of the affiliated colleges, several members of Parliament, and the Graduates Committee, for the purpose of carrying out this object. The question for admitting the principals and professors of the affiliated colleges, both medical and general, into the franchise, became a subject of careful consideration, and, at present, remains undecided. However, the decision did not rest with the "Committee of Graduates", but with the "Franchise Committee", composed as above, in which the interests of the professors are fully represented. And without wishing in any way to anticipate the decision which may be come to, I may state, that some of the professors, who at the commencement of the movement most warmly supported the introduction of the "professorial element" into this franchise, have now given it up; whilst the inquiries of the "Franchise Committee" have led to the development of difficulties in the working of the scheme, which no means have yet been devised to surmount.

I feel that I am expressing the opinion of the Franchise Committee, when I say, that they will be much gratified to know they have the influential support of the medical profession in the provinces, as well as in London, in their endeavour to obtain representatives in Parliament for the University of London.

I am, etc.,

T. SNOW BECK, M.D.,

Secretary to the Franchise Committee.

January 14th, 1853.

NEWS AND TOPICS OF THE DAY.

AMALGAMATION OF THE ORDNANCE AND LINE MEDICAL DEPARTMENTS. There is a rumour, that the Medical Departments of the Line and Ordnance are very shortly to be amalgamated. Such a change will be one of convenience and economy to the Service. It has occurred to us that a very good opportunity would be afforded at this time to remove an expense which medical officers of the Line, rather unjustly, as it would seem by comparison with others, have long been subjected to. In accordance with present regulations, assistant-surgeons of the Line have to provide, at their own expense, a pocket case of instruments, and regimental and second-class surgeons, in addition, a capital case of instruments, for the public use. The latter case of instruments, according to regulation, costs about 30*l*. But the singular part is, that on promotion to the first class, the surgeon is no longer required to have this case of instruments, but is provided with one at the public expense. Now, in the Ordnance department, the assistant-surgeons and surgeons have always been provided with the required instruments at the public cost, just the same as holds in the Navy. Surely this appears only just, and equally ought to apply to the medical officers of all branches of the Service, all being made alike responsible for the proper care and keeping of the public property alluded to.—*United Service Gazette*.

ST. GEORGE'S HOSPITAL: MR. KEATE'S RESIGNATION. Mr. KEATE, who has so long and so ably filled the office of Surgeon to St. George's Hospital, has tendered his resignation of that post. It is believed, that Mr. C. H. Johnson, at present one of the Assistant-Surgeons, will be appointed to succeed him; and that Mr. Pollock will take the place of Mr. Johnson.

GLASGOW MEDICAL JOURNAL. There is at present on foot a project for reviving the Glasgow Medical Journal, under the editorial auspices of Dr. Weir, one of its former conductors.

THE COMMISSIONERS IN LUNACY. There has just been printed, by order of the House of Lords, a paper containing the report made to the Lord Chancellor by the Commissioners in Lunacy, of visits to insane persons during the six months ending the 4th of August last. Dr. Turner made 123 visits, saw 6,237 patients, and travelled 3,973 miles. Dr. Hume made 152 visits, saw 5,511 patients, and travelled 5,604 miles. Mr. Gaskell made 137 visits, saw 7,708 patients, and travelled 4,676 miles. Mr. Proctor made 100 visits, saw 5,515 patients, and travelled 3,809 miles. Mr. Mylne made 158 visits, saw 7,808 patients, and travelled 5,819 miles; and Mr. Campbell made 131 visits, saw 7,073 patients, and travelled 4,320 miles.

DR. J. DE CARRO, OF CARLSBAD. By the Carlsbad papers of the 12th instant, we learn that his Majesty, Otho I., king of Greece, has conferred the Order of the Saviour upon Dr. de Carro, as a mark of his esteem for this veteran physician, and in particular as a testimony of his services to humanity, in having introduced vaccination into Greece.

OBITUARY.

BRUCE, Samuel Barwick, M.D., of Ripon, Yorkshire, for many years Surgeon to the Forces, at Victoria Square, Grosvenor Place, London, on 24th Dec. 1852, aged 66. Dr. Bruce was born on 8th January 1786. He was the second son of Mr. Barwick Bruce, and the grandson of the Hon. J. O. Bruce, of Garilet, county of Clackmannan (who was some time judge of the Court of Common Pleas, in Barbadoes), by Jane, the daughter of General Samuel Barwick, who was governor of that island. Dr. Bruce entered the medical department of the army in 1804, but saw some of his earliest service afloat under Lord Nelson, in 1805; he was present at the capture of the Danish islands of St. Thomas, St. John, and St. Croix, in 1807, and he subsequently served at the siege of Fort Desaix, Martinique (for which he had a medal and clasp); at the capture of Les Saintes, near Guadaloupe, at the bombardment, and driving from their anchorage of the French fleet, in 1809; at the capture of Guadaloupe (for which also he received a medal and clasp), as well as at the capture of the adjacent islands, in 1810. Dr. Bruce served in the Peninsula in 1813, in America in 1814 and 1815, and was present at the severe actions before New Orleans, in January 1815; at the capture of Fort Boyer, etc. He joined the army in the Netherlands, under the Duke of Wellington, in May 1815; was present at

Waterloo, and at the subsequent capture of Paris. He died very suddenly, after an apoplectic seizure.

PEREIRA, Jonathan, M.D., F.R.S., on Friday, January 21st, at his residence in Finsbury Square, in his 40th year. He was Physician to the London Hospital, and an Examiner in Materia Medica and Therapeutics to the University of London. About five weeks ago, Dr. Pereira visited the College of Surgeons for the purpose of consulting Professor Quekett on a microscopical investigation; and whilst descending the stairs leading to the new building now erecting, missed his footing and fell heavily to the ground, thereby rupturing the tendon of the patella. In all probability, at the same time some internal injury was sustained by the heart or larger vessels; but no indication of this was evinced until twenty minutes before his death, when he felt a sudden and violent throb in the region of the heart, when he became fully aware that a speedy termination to his life was at hand. He sent for a medical friend in the immediate neighbourhood, informed him that he was dying, and requested him to remain with him and his family until life had passed away. Dr. Pereira was a man of portly bearing, good-humoured, and of great frankness of manner. Few men were possessed of such general and sound knowledge of subjects connected with his profession with so little affectation. He was an excellent observer in Pharmaceutical Microscopy and Chemistry. He had a good idea of what was practical; his literary judgment was very sound. He was author of *Elements of Materia Medica and Therapeutics*, a work of universal reputation,—the concluding portion of the Third Edition he was actively engaged on up to the time of his death. He also wrote a treatise on *Food and Diet; Selecta à Prescriptis*; and *Lectures on Polarised Light*,—the best familiar exposition of that abstruse subject in our language. He also contributed numerous articles to societies, journals, reviews, etc. His death has left a great void in English Pharmacology, as no one in England had a greater amount of knowledge on that subject. As a lecturer, he secured the attention of his class by an earnestness of purpose, aptness of experimental illustration, and the practical bearing of his remarks. Like John Abernethy, he was fond of introducing jocose anecdotes into his lectures, not only to secure attention, but as aids to memory. To those students who evinced a desire for information, he was ever most liberal in affording assistance, often devoting valuable time in making them thoroughly acquainted with the subject of their inquiries. Dr. Pereira was, at the commencement of his medical career, apprenticed to a general practitioner—attended the Aldersgate Dispensary—became its Apothecary—took his degree in medicine, and became Lecturer on Chemistry and Materia Medica at the Dispensary, where his lectures attracted many students from neighbouring schools of medicine. He continued there till the disruption of the medical staff of that establishment. He afterwards became Lecturer at the London Hospital, which post he resigned about three years since. He was also one of the physicians to that hospital up to the time of his death. He also lectured at the Pharmaceutical Society, and was Examiner on Materia Medica to the London University for many years. He attained his high position in the profession ENTIRELY through his own industry and acumen.

EDITED BY JOHN ROSE CORMACK, M.D.

No. V.

LONDON: FRIDAY EVENING, FEBRUARY 4, 1853.

NEW SERIES.

VERDICT OF MANSLAUGHTER RETURNED AGAINST MR. HICKS, BY A CORONER'S JURY.

THE verdict of "manslaughter", brought in against Mr. Hicks, surgeon, of Toddington, Bedfordshire, is so startling, and so suggestive of evils that ought to be speedily remedied in medical jurisprudence, that we feel ourselves impelled to comment on the details of the case.

The facts are these:—Mr. Hicks was called to attend a boy who, it was supposed, had injured his leg by a fall. As Mr. Hicks at first believed that the fibula had been broken, the limb was bandaged, and pasteboard splints were applied. Afterwards, as Mr. Hicks, jun., suspected that an abscess was forming under the knee, the splints were removed, and a poultice was applied to the whole limb. Next, Mr. BENSON, surgeon, of Luton, was called in; but not until the patient was all but moribund. This gentleman, assisted by Mr. TOMSON, made a *post mortem* examination, and found no fracture, but some pus infiltrated among the muscles below the knee-joint. On these evidences, they founded their very decided opinion, that *death resulted from disease of the brain, produced by the pressure of the bandage*. The jury, ruled by such a positive and unqualified assertion, returned a verdict of *manslaughter*; and, accordingly, Mr. Hicks was committed to prison under the coroner's warrant!

Surely, this is a rather important case for the consideration of medical men, who value life, liberty, and reputation; for it immediately suggests the query, "Who is safe?" Commitment for "manslaughter" may be, it seems, easily brought about, any day, for any practitioner who has the ill fortune to find two professional brethren ready to give a positive opinion against him, and a non-medical coroner disposed to respect dogmatic assertions. With less respect and more suspicion, we shall now say a few plain words about this rather portentous inquest.

Admitting the mistake in diagnosis, and that the first treatment of the case was quite improper for an abscess, still we do not feel ourselves compelled, by the authority of Messrs. Benson and Tomson, to leap, in their very agile style, to the conclusion that death resulted solely from the wrong treatment. We have seen cases of deep-seated abscesses in the neighbourhood of joints, which have terminated fatally, though the best mode of treatment had been employed. Absorption of matter often takes place, without any pressure from bandages. Whether the effect of accident or not, it is evident that there was local mischief, and, if not the result of the accident, the same cause which produced that local mischief in the limb *might* also lead to fatal mischief in the head. Or, is it not *possible* that the cerebral disorder may have been merely a coincidence, not in the least dependent either on the injury of the knee, or on the plan of treatment adopted? Who can say that the cerebral disease would never have manifested itself, but for the injury of the limb? We do not see anything in the

evidence to set aside these doubts, though Messrs. Benson and Tomson did not hesitate in stating their belief, that the cerebral disease must be attributed *solely*, as an effect, to the treatment pursued by Mr. Hicks. Surely, where so much room for modest and reasonable doubt existed; where the reputation of a fellow-practitioner was at stake; and where they knew that their mere opinion would be the main evidence in the case,—it would have been more becoming, in every respect, if the medical witnesses had been rather less dogmatical.

But, again, admitting the mistake of treatment, there is, or there ought to be, a wide distance between a mistake in medical practice and "manslaughter", which implies, as we think, a criminal degree of ignorance or neglect in the treatment of a case. Again comes the question—"Who is safe" if inquests are to be conducted in the above-mentioned style? Not, we reply, the most eminent and the most honest practitioners. We have known celebrated hospital surgeons who have unhappily punctured a distended bladder for ascites—who have opened an aneurismal tumour for abscess—who have even plunged the lancet into a hernial swelling—and who have committed many other fatal errors. We remember that "to err is human". We will even go so far as to say that Messrs. Benson and Tomson—clear, rapid, and positive as they seem to be in coming to conclusions—that even they themselves have sometimes made mistakes; that, if the veil which hides unknown errors could be lifted, it would disclose some few errors, even in their practice, as in that of the most skilful and conscientious of our profession. If great men, then, have made great mistakes, we can conceive it possible that Mr. Hicks, of Toddington, may have concluded that the fibula was broken after a fall; and that, on the faith of such a conclusion, he applied the usual splints and bandages, without being guilty of *manslaughter*.

We must now add a few facts, on which we shall not comment at any great length. Mr. Hicks, it appears, has been in practice more than forty years, and claims a legal right to practise, as having practised before the Apothecaries' Act of 1815. He has a son now studying at one of the London schools, who will shortly have finished his medical education; and another son is apprenticed to the father at the present time. It also appears that he has been called in by some of the patients of the two medical witnesses against him in this case. Mr. Hicks and his sons were *not invited* to the *post mortem* examination, *nor had they any intimation of it* until the day of the inquest! This is strange, to say the least of it; and sufficient, in itself, to impair the medical evidence of Messrs. Benson and Tomson. The coroner should have summoned the attendance of an impartial medical man, having no local associations in the neighbourhood; or, at any rate, he should have insisted on having two sides to the case, by the presence of some one to protect the interests of the accused party.

The practical lesson to be deduced from the whole affair is this—we want a fair and honourable code of medical

ethics, for the general guidance of the profession in many delicate cases where it is commonly found that the most incompetent are the most positive in their own opinions; and we also want impartial and thoroughly-educated MEDICAL CORONERS. Where a coroner's legal knowledge avails once, his knowledge of medical science would avail a dozen times. We venture to say that, had this painful case come under the notice of a *medical*, instead of a *legal* coroner, the evidence given by Messrs. Benson and Tomson would have been so qualified and abated, that we should have been spared the pain of commenting on a verdict, which we, last week, designated as manifestly "absurd and unjust."

It is said that, in Abyssinia, though the people are really fond of physic and addicted to begging for it, the practice of medicine is unpleasant for a nervous man. A Mr. Johnstone, while travelling there, had given some harmless pills to a chief who was ill. Afterwards, on awaking in the night, the amateur doctor was surprised to find his tent surrounded by natives armed with spears, and under the command of the wife of the patient. On asking the reason of this hostile display, he was quietly told that "the medicine had not yet operated well; and, as it was thought probable that the chieftain might die before morning, it was resolved, in that case, to send the doctor after him as quickly as possible." Luckily, the sick man recovered; but Mr. Johnstone was afterwards rather shy about dispensing physic in Abyssinia. There is something rather Abyssinian in the late rapid decision at Toddington.

Seriously, we must have some code of ethics among ourselves; or we must seek the aid of the legislature to prevent the recurrence of such cases. For, if inquests are to be conducted in the style on which we have commented; if mistakes in diagnosis are to be metamorphosed into manslaughter; if *post mortem* examinations on our fatal cases are to be made by our competitors closeted together; if their *ipse dixit* is to pass as law with coroners; then our profession may be styled a dangerous one *par excellence*. We may envy the safety and peace of mind of coal-miners and engine-drivers; for every morning as we go forth to our perilous duties, we must be haunted by the thought that, some day, our professional neighbours, assisted by a non-medical coroner, may kindly suggest to Government the propriety of inflicting upon us—emigration in the compulsory style.

THE STUDY OF BOTANY.

We propose to bring before the notice of the profession from time to time, some of the more interesting discoveries in Botanical Science which appear to have a bearing on Medicine in its Anatomical, Physiological, Therapeutical, and Hygienic departments. It has too often been the habit of some practitioners, especially in the surgical province, to deny the merits of the sciences which are collateral to medicine. Their condemnation proceeds upon an erroneous view of the value of these sciences, as well as of the mode in which they should be prosecuted. In the case of a medical student, the sciences must be viewed not merely as regards their bearings on the actual treatment of disease, but also as regards the influence which they exercise on his mental development. One of the most important uses of botanical science, for instance, to the student, is to train him to correctness of observation and accuracy of diagnosis; qualities which are most essential for the successful prosecution of his profession. Hence we argue that such studies should be

preliminary to his entrance on the more practical parts of his professional career, so that their influence may extend over the whole period of his studies.

No one can be a scientific physiologist, who does not embrace in his researches both the animal and the vegetable kingdom. The examination of vegetable tissues and organs, with their mode of development and their functions, has led to most valuable results in human physiology. The modern doctrines relative to cell-life in all its stages have been founded in the first instance on the phenomena observed in plants; and the subject of embryogeny has been elucidated in no small degree by the labour of vegetable physiologists.

The influence which climate and soil produce on the properties of plants must be studied by the scientific therapist, if he desires to know the qualities of the remedies he employs. The medicinal products of plants are materially affected by these circumstances. Look, for instance, at the difference between the secretion of the hemp plant as cultivated in India and in Britain. In the former country it has powerful narcotic qualities, while in the latter it is comparatively inert. Notice also the varying properties of the same species of umbelliferous plants, according to the situations in which they grow.

The plants which cover the surface of a country have also in their turn a marked effect upon climate, and assist in the determination of its nature. The physical effects of the removal of forests, for example, is a subject which calls for the attention of the climatologist. Humboldt remarks:—"By felling trees which cover the tops and sides of mountains, men in every climate prepare at once two calamities for future generations—the want of fuel and the scarcity of water. . . . Plants exhale fluid from their leaves, in the first place, for their own benefit. But various important secondary effects follow from this process; one of these is maintaining a suitable portion of humidity in the air. Not only do they attract and condense the moisture suspended in the air, and borne by the wind over the earth's surface, which, falling from their leaves, keeps the ground below moist and cool; but they can, by means of their roots, pump it up from a very considerable depth, and raising it into the atmosphere, diffuse it over the face of the country. Trees, by the transpiration from their leaves, surround themselves with an atmosphere constantly cold and moist. They also shelter the soil from the direct action of the sun, and thus prevent evaporation of the water furnished by rains." In this way the forests contribute to the copiousness of streams. In those mountains of Greece which have been deprived of their forests, the streams have disappeared. The sultry atmosphere and the droughts of the Cape de Verd islands are attributed to the destruction of forests. It is stated that in large districts of India, climate and irrigation have rapidly deteriorated from a similar cause, and that the government are now using means to avert and remedy the mischief. We thus perceive that the vegetable kingdom has a powerful influence in modifying the climates of the globe.

These are not the days in which a physician can acquire fame and reputation, who shows ignorance of the natural sciences. He cannot expect to secure the confidence of his patients, nor can he occupy, in a satisfactory manner, offices of responsibility, either in this country or abroad, unless he show himself to be conversant with these subjects. It is to the medical profession that the public look, in an especial manner, for enlightenment in science, and it is certain that without it the profession cannot continue to

maintain its eminent position. Let us hope that medical men are now recognizing, more than ever, the important bearings which the natural history sciences have upon their studies, and that the time is not far distant when the reproachful term *unscientific* shall not be applied with truth to any member of our noble profession.

MEDICAL HISTORY.—PAST ERRORS TEACH USEFUL LESSONS.

We find from various letters which we have received, that many of our readers are inclined to criticise the opinions we have expressed on the subject of Medical History. Some are disposed to think, that Medical History is of scarcely any importance whatever; others say, that we have underrated the state of knowledge concerning it; and a third class maintain, that if unknown and valuable facts do of a truth exist in the past book-world of medicine, they are too largely diluted by, and commingled with, absurd errors, to be worth the labour of being sought after. To all these assertions, we have one answer:—they are made without due consideration of the Philosophy of History, and without a sufficiently extended conception of the applications of historical information. Let us dwell a little on this answer, for it deserves attention, and affords us a basis on which to build arguments in opposition to the objections stated above.

In the first place, then, we freely admit, that a great amount of exceedingly valuable information of the Medico-Historical kind has already been collected by several competent authors,—by such men, for instance, as Sprengel, Le Clerc, and Friend. Our admiration of these writers goes so far indeed, that we would give them rank with such political historians as Hume, Gibbon, and Robertson. Can we say more in their favour? We can. The imperishable works of the medical historians referred to are text-books, from which every modern writer on the same branch of history must borrow information, and on which alone he might found the most valuable expositions. But, because we hold this high opinion of these learned text-books, are we to say that in them the subject of Medical History has been exhausted? As wise would it be for us to declare that the works of Hume, Gibbon, and Robertson, have exhausted those peculiar departments of history on which they treat, and that the immortal labours of our latter-day Hallams, Niebuhrs, and Grotes, have come into an unnecessary existence. We believe we may safely lay down as an axiom the assertion, *that the history of any science so useful, so extensive, and so ancient withal, as is the science of medicine, can never be exhausted.* We are desirous not to be misunderstood on this point. We use the word History in a dual sense, for in such a sense it should always be used and understood. The mere narration of events, the records of the lives of men, and so forth, are, it is true, historical labour; and so far history may have an end. But this is in fact only the half of the matter! the philosophical ideas, of which these mere historical narrations form but nuclei, remain, and not only call into play distinct forms of mental faculty, but open a field for investigation quite inexhaustible. Now we are bold to affirm, that the History of Medicine has as yet not even been entered upon in this last named philosophical lesson-teaching sense. It is not sufficient for us to know, that at such a time, some distinguished man lived, or some peculiar sect existed, or that a wonderful discovery was made. We want to be informed

what influence the man, the sect, or the discovery, had on his or on its time? what on after times? what influence he or it has now? We require to know, moreover, why those men who take rank as distinguished men are distinguished? what plans of investigation they pursued? what right they have to their distinctions? and, lastly, we would, if it were possible, discover the pit-falls and errors into which they fell. We repeat, that we would desire to know the errors of our distinguished men. This, strange as it may sound to some ears, is a legitimate wish. It has been said by one of the greatest men that ever lived, that “there is a soul of goodness in things evil, would men observingly distil it out”; and it may be, that no sentence of fifteen words ever expressed a more profound or accurate idea. The sentence, without losing either its force or its correctness, may be so modified as to express our present thoughts: “there is a soul of *truth* in things *false*, would men observingly distil it out”.

With the system of fighting with error, we are no friends; that system involves loss of time, loss of intellect, loss of everything; it were as wise to strike at shadows. But we do believe the *observance* and *remembrance of error* to be a wholesome and an excellent practice. In our lives we universally use this practice; and in sentences similar to these, “I shall be wiser next time”, “I shall take a lesson from that mistake”, etc., we almost hourly acknowledge the advantages of it; nay, we have it reduced to rule even, in the well known poetical proverb—

“The strongest plume in wisdom’s pinion,
Is the memory of past folly.”

And the practice here named, so useful in our special concerns, admits of a wider application, an *historical* one. For history, whether dealing with mankind altogether from first to last, or with classes of mankind, is, after all, but an expounded record of the wisdom and error, of the goodness and evil, of the joys and the sorrows, of the life, in short, of one vastly magnified long-living man. The History of Medicine may be conceived as the pictured life of a single mighty Esculapius, embracing in his career all medical men of all times, and yet typified in miniature in every living member of the medical body. Thus it may be said, that the acquirement of information on Medical History by the medical man, is nothing more than an endeavour on his part to fulfil the golden precept of the Delphian Temple, “to know himself”.

We have advanced too far on this occasion, to descend from the expression of general ideas to the introduction of particular statements. It will afford us, however, great pleasure to return to this subject, and to show, by reference to one or two interesting historical facts from the practice of medicine, the truth of the principle we are so anxious to establish, that the very errors of the past medical body might be turned to useful account.

But some one will ask, How can I raise myself to the standard of knowledge supposed above? How is it possible for me so to assimilate myself with the past, as to become a living personation of all medical men, back to the medicine god of Grecian mythology? We would be the last to affirm that such an accomplishment is in any way possible; but we do affirm that every one might advance towards it; and that he who approaches it nearest, shall be greatest in his own time, and shall dissolve least slowly in the future.

ORIGINAL COMMUNICATIONS.

CASES OCCURRING IN THE MEDICAL PRACTICE OF THE SUSSEX COUNTY HOSPITAL DURING THE YEARS 1849, 1850, AND 1851; WITH REMARKS.

By G. S. JENKS, M.D., one of the Physicians to that Institution.

THE following essay is compiled from three papers which I read before the Medico-Chirurgical Society, at Brighton, in the years 1850, 1851, and 1852. I was led to introduce these reports for discussion, as now I am to publish them from a conviction, first, that the results of hospital practice may be useful in their application to the exigencies as well as the statistics of a difficult and laborious profession; and, secondly, because I regard all institutions, supported by public charity, as having incurred a debt of usefulness to the whole community. The cases described occurred under my own care; and the nosological plan which I have adopted, is that of the Registrar General.

ATMOSPHERIC CONDITIONS IN 1849, 1850, AND 1851.

In 1849, the early part of January, and the latter part of March, were cold and dry, with sharp north-easterly winds, but the intervening period was unusually warm for the season, and the winds westerly. April, May, and June, were cold and wet, the mean temperature being below the average, with an excess of rain. The summer months, on the contrary, were warm and dry, without excessive heat, and with less rain than usual, the wind being from the east. The autumn set in very cold, but afterwards the season, till the end of the year, was, upon the whole, mild, and the weather damp and foggy, under a prevalence of wind varying from north-west to south-west.

In 1850, during the spring and summer, easterly and northerly winds generally prevailed, with dry weather. The autumnal and winter months, on the other hand, were characterised by frequent gales, and much rain. It may be predicated of the whole year, that it presented the phenomena of a mild, genial climate: for, excepting some sharp frosts, which did not last long, in January and March, the seasons were temperate, being remarkable neither for great heat nor cold, dryness nor moisture. The epidemic constitution of the year was not marked by any virulent outbreak of the usual maladies.

In 1851, the epidemic constitution was, upon the whole, favourable. The early part of the year, unusually warm and open, was followed by a somewhat ungenial spring. In the latter part of April, and the beginning of May, cold north-west winds, with chilling rains and sharp frosts in quick alternation, did much damage to vegetation, and destroyed nearly all the wall-fruit. Much rain fell during the months of June and July; and to this succeeded a long continuance of fine, warm, clear weather. Towards the end of autumn, the weather became very cold. November was remarkable for dry winds and sharp frosts: December, on the other hand, like the first month of the year, was singularly mild and open. The prevailing winds, till August, were westerly, with frequent heavy gales. During the fine weather which succeeded, they varied from north to north-east and north-west. The mean temperature of the two winter months, January and December, was 46°; that of the summer months was 61°.

EPIDEMIC DISEASES.

Looking at the vast extension of Brighton now going on, and the constantly increasing number of its inhabitants, amounting to 67,000, we must expect to approximate more nearly, every year, to the average rate of disease and mortality in other large towns. Of so growing a population, the most needy must be densely crowded, and not a small proportion of those in better circumstances

will be bestowed as to sanitary conditions. But, besides this, the free and constant intercourse with the metropolis and all parts of the country, and the cheapness and facility of travelling, bring us, besides a host of paupers, a continual influx of invalids, and convalescents from infectious maladies. Notwithstanding these extraneous sources of epidemic and contagious diseases, I believe that there has not, during the years embraced in this report, prevailed a greater amount than usual of these diseases, with the exception that thirteen cases of typhoid fever, some in its worst form, were admitted between June and December, 1851.

TYPHOID AND TYPHUS FEVER. In 1849, not a single case of typhus or typhoid fever came under my care; and, I believe, few, if any, under that of the other physicians. In 1850, two cases of typhoid fever were admitted: one a boy, eleven years of age; the other a young man, aged twenty-three. We could discover no eruption of a decided character in either case; but from the urgent abdominal symptoms—great tenderness and intolerance of pressure, severe diarrhoea, and yellow-ochrey stools—we inferred that Peyer's glands were affected; and, relying on Dr. Jenner's authority, we have denominated them cases of *typhoid*, not *typhus*, fever. In both cases there was delirium: but the boy exhibited the phenomenon of total loss of speech, without previous coma, on the sixteenth day after admission (being the twenty-fourth of the disease), his intellect remaining unimpaired. There was, however, very defective power of voluntary motion; he might have been said to be completely paralysed. When placed upright, his head rolled from side to side, or hung forward upon his chest. All his motions were impeded, and without precision. These symptoms gradually disappeared; and the boy made a good recovery.

Several cases were admitted under the head of gastric fever. They were not attended with symptoms of prostration, but were characterised by considerable disorder of the digestive organs, with fully developed fever. One case, towards the conclusion, became complicated with bronchitis; another was remarkable for a very frequent pulse, which persisted long after convalescence.

In 1851, fever of a typhoid type prevailed more extensively. According to the distinction now made between typhoid and typhus fever, I would say that five well-marked cases of typhoid fever came under my charge. Rose-coloured papulae appeared on the thorax and abdomen in three cases; red patches in one: and no eruption could be discovered in a fifth. Diarrhoea, with abdominal tenderness, especially in the right hypogastric region, occurred in four cases; costiveness, with abdominal tenderness, was present in one only. Profuse intestinal hæmorrhage happened in two cases, in one of which it was fatal. The admissions took place from the seventh to the eleventh day. One case terminated favourably on the eleventh day; another on the fourteenth; two on the twenty-first.

One poor boy, aged 16, died on the nineteenth day, from the effects of profuse hæmorrhage, which had begun on the fourteenth, at a time when the other symptoms promised a favourable issue. On examination of the body, thirty-two hours after death, decomposition had already commenced in the walls of the abdomen. The thoracic viscera were healthy; the liver showed no signs of disease; the spleen was softer, but not larger, than natural. The ileum, at its terminal portion, was extensively ulcerated. The ulcers were on the opposite side to the mesentery, of an elliptic form, the long diameter being parallel with the longitudinal axis of the intestine. Some were very long and very deep, the serous coat alone remaining intact. About the middle of the ileum there was a diverticulum about two and a half inches long, in which was a large and deep ulcer. The blood-vessels of the mesentery, and their ramifications between the intestinal coats, were enlarged, and injected with dark blood. Some large vessels were in immediate contact with the deep ulcers, especially those situated in Peyer's glands. The solitary glands were generally enlarged, and very conspicuous.

Three other cases of fever occurred, two in men, and one in a woman, which I have little doubt were mild examples of the prevailing epidemic; but as the chief characteristics of the typhoid type were absent, or only slightly manifested, they are classed as continued fever.

In the two men there was a complication of bronchitis. The woman had fever, without any complication. Two of the cases were admitted on the eighth day of the disease: the third, a groom, at the end of the third week. The case of the female terminated on the fourth day. The disease lasted longer than twenty-one days in both the men, being prolonged by bronchitis. Headache, constipation, and some abdominal tenderness, occurred in all three; but no eruption could be detected.

AGUE. In 1849, two cases were admitted. One was a servant girl, aged 19, who was attacked with the disease in Brighton. Besides these, two men applied as out-patients, with tertian ague, who had not been out of Brighton for five or six months.

ERUPTIVE DISEASES. In 1849, one case of small-pox, after vaccination, was admitted. It presented no febrile symptoms after the eruption broke out. Several cases of mild scarlatina, and of erysipelas, went through their course, without any phenomena worthy of remark; and the same was the case in 1850 and 1851.

ACUTE RHEUMATISM. In 1849, rheumatic fever, or that form of acute rheumatism attended with high fever and inflammation of the fibrous structures, in which the heart and pericardium are prone to be involved, was of frequent occurrence, especially among female servants, living exposed to draughts of air, in cold, damp kitchens, below the level of the street. Six cases were admitted; two males, and four females. Of the females, three, of the respective ages of 12, 15, and 16 years, suffered from pericarditis, or endocarditis, or both. One girl, S., aged 16, was seized with severe pericarditis, attended with copious effusion, soon after the appearance of the arthritic pains. Afterwards, and during the persistence of pericarditis, she was attacked with endocarditis, and subsequently with double pneumonia. She was discharged cured on February 13th, 1850, having been in hospital seventy-three days. I heard of her in the autumn as being quite well; but had no opportunity of examining the state of her heart. The girl aged 12 had pericarditis, endocarditis, and incipient pneumonia of the left side. The third, aged 15, had endocarditis, without any other complication. In the other three cases—two men and a woman, in the latter of whom the rheumatic attack appeared to be connected with uterine disorder—there were no cardiac symptoms. The duration of the arthritic affection was from one week to three. All the cases did well. It is worthy of remark, that, in the two cases of pericarditis, which preceded the affections of the endocardium and lungs, endocarditis and pneumonia were developed while the patients were under the influence of mercury and opium; and that all three cases of cardiac complication occurred in very young subjects.

In 1850, three cases only were admitted. In one of them, C. R., a woman aged 40, the disease was slight, and yielded speedily to purgatives, alkalis, and colchicum. A second, F. R., aged 18, had been bled and cupped for an incipient endocardial affection, and calomel and opium had already been administered before I saw her. The mouth became sore; the acute symptoms and pain were subdued in ten days. She remained thirty-four days in hospital. The endocardial murmur still existed, when she was discharged. The third, a young man, aged 20, suffered from a severe attack: both knees and ankles were affected, and afterwards the shoulder and wrist of the right arm. There was much external swelling and hardness about the throat. A harsh murmur with the first sound of the heart was heard on the third day after admission. This case was treated with purgatives in the beginning, followed by large doses of nitrate of potash. During the treatment, the pulse fell gradually from 88 to

40, and did not rise to 60, till nine or ten days had elapsed. All fever and pain had subsided in eight days. The cardiac murmur ceased long before his discharge, which took place on the twenty-seventh day after admission. I had no fair opportunity of trying the efficacy of lemon-juice in acute rheumatism.

SCORBUTUS. A case of scorbutus, in an old man of 73, was admitted, of greater severity than is often met with in our days. He had been ailing six months. His diet had been poor, and he had avoided vegetables, believing that they disordered him. Extensive vibices had appeared on his body, about six weeks before his admission, on July 2nd. These had been preceded for a month by very severe pains. These vibices, on the posterior and inner part of the left thigh, presented the appearance of large extravasations of blood. The skin covering these bruises, as they seemed to be, was hot, somewhat tense, and very tender under pressure. His sleep was prevented by constant pain; he suffered much from hiccup; and was extremely depressed in his spirits. His gums were spongy; livid fungous granulations had sprouted up around some bad teeth, and bled on the slightest touch. He was allowed a double portion of fresh vegetables with his food, and three oranges a day. He took the citrate of iron, with lemon-juice and cinnamon-water, thrice daily. In a month he went out quite well.

DISEASES OF VARIABLE SEAT.

CANCER. In 1850, a case of malignant disease of the œsophagus was admitted, in which the dysphagia became at length inability to swallow, from obstruction of the tube. This patient, a female, aged 50, had likewise prolapsus ani to an enormous extent. She died from inanition; yet, on opening the body, there was a copious deposit of subcutaneous fat in the anterior walls of the abdomen. The intestines were all of a dark colour, and much collapsed; the stomach was not larger than a portion of dilated intestine. About three inches above the cardiac orifice, was found a morbid growth adhering to the trachea, and surrounding and compressing the œsophagus for the space of two inches, so that its calibre was reduced thereby to about the diameter of a No. 3 catheter. In the middle of this constricted part, was a small excavated ulcer, which might have held a pea. This growth on section was of a buff colour, and had rather a firm consistence. In the cavity of the uterus, attached to the fundus, lay a small polypus, about as large as a horse-bean. On the os uteri was found a small ulcer, and on the surrounding parts were patches of abrasion of the mucous membrane, caused, seemingly, by the contact of acrid discharge from the contiguous ulcer. The rectum was of a very dark colour, exhibiting signs of intense congestion. The other viscera were healthy.

TUBERCULAR DISEASES.

PHTHISIS. In 1850, two men died from phthisis: one from profuse hæmoptysis. About the root of the left lung, were several irregular cavities; one of which, after the loose clots of blood were washed out, was found to contain a hard laminated coagulum adhering to its walls. The pulmonary artery was injected, with the hope of discovering the ruptured vessel, but without success. The other man presented an example of acute phthisis. Both lungs were filled throughout with innumerable milary tubercles, which, at the apices, had commenced the process of softening. In this case, there had been intercurrent pneumonia; the dyspnoea was extreme. In nine other cases of phthisis, cod-liver oil was exhibited with more or less advantage, but in all the cases with some relief. Where cavities existed, the benefit consisted merely of an abatement of cough, fever, and expectoration; the physical signs remaining the same, and the body sometimes, though rarely, acquiring more flesh. Where the disease was less advanced, the good effects were more conspicuous; not only did the fever, cough, night-sweats, etc., subside, but

the patients became fat and strong. This was especially observed in a girl of one-and-twenty, Parker, whose condition when admitted was most unpromising.

In 1849, the following case of tuberculosis of the lungs and intestines was admitted :

CASE. A girl, aged 21, was admitted Jan. 31st, with severe gastro-enteritis, for which she had been under homœopathic treatment. There were signs of ulceration of the intestines, with circumscribed peritonitis. She had hectic fever and diarrhœa. On examining the chest, the physical signs of tubercles in a state of softening were present at the apices of both lungs, but especially the right. The cough was very troublesome, and added much to her sufferings. Throughout the month of February, the ulcerated state of the bowels, and the diarrhœa and peritoneal inflammation consequent thereon, demanded our chief attention; but on the 11th March, she was seized with a severe attack of pleuritis of the right side, followed by abundant effusion. There was extensive dullness on percussion, and absence of respiration posteriorly, except quite at the upper part of the lung; but anteriorly there was vesicular breathing, and resonance on percussion, which was afterwards explained by adhesions which had tied down the base of the lung anteriorly to the diaphragm. She died, on the eleventh day after this attack of pleurisy.

Autopsy. The head was not opened. There were old partial adhesions of the pleura on both sides. The right pleural cavity contained about a quart of serum. There were old adhesions anteriorly, binding the lung to the diaphragm. Both lungs contained numerous tubercles. There was a small vomica at the apex of the right lung. The liver had undergone fatty degeneration. There were adhesions of the convolutions of the intestines in several places, and also to the parietes of the abdomen in the left iliac region. The ulcerations of the intestines, which were confined to the ileum, were visible through the peritoneal coat. Some appeared to have undergone a healing process; others were large and deep, spreading in the direction of the circumference of the intestine, and destroying the mucous and muscular coats down to the peritoneum. The mesenteric glands in the vicinity of the ulcerations were enlarged. The case was probably in the beginning one of intestinal tuberculosis.

In 1851, five men and one woman were admitted with phthisis pulmonalis. With but one exception, none of them presented the stethoscopic signs of the last stage of the disease. One woman died of the acute form of phthisis, which appeared to be accelerated by the retrocession of a cutaneous eruption, which had long troubled her. An examination of the body was not permitted. The other cases, after a sojourn in the hospital of from two to ten weeks, were discharged, some more, some less, but all much relieved by cod-liver oil. In one man, Richard Vernon, the good effect of this remedy was very remarkable. He had had the usual signs of softening of tuberculous matter at the apex of the left lung for two years. In February he entered the hospital for the second time. There were cavernous respiration and cough, distinct gurgling, and painful resonance of the voice. On percussion, amphoric resonance was elicited. After two months' treatment with cod-liver oil, this man was discharged, much improved in flesh and strength. He has persevered in the use of the oil, as an out-patient, ever since, and has been able to follow his employment as a milkman through the whole of the winter. He still preserves his condition, but the signs in the left lung remain unchanged. On the right side, where dullness on percussion and bronchophony existed, the disease seems to have been arrested. With an improvement of flesh and strength, under the use of the oil, the night-sweats disappeared, but the cough was not diminished in the same proportion.*

STRUMA. Ebenezer Vincent, æt. 10, a puny, emaciated boy, presented the following symptoms. An enlarged and tense

abdomen, without fluctuation, very tender when touched; the superficial veins being distended and numerous ramified. He had a troublesome cough, with much expectoration. Sibilant and sonorous rhonchi were heard at the base of both lungs posteriorly. He had hectic fever, and profuse night-sweats. Cod-liver oil, syrup of the iodide of iron, and a mixture for his cough, were administered internally. A liniment of camphorated oil, with iodide of potassium and laudanum, was well rubbed over the abdomen, night and morning. Sea-water baths were also ordered. In two months, the boy was discharged convalescent,—his improvement having gone on steadily from the beginning.

DISEASES OF THE BRAIN, SPINAL MARROW, AND NERVES.

MENINGITIS. The following case occurred in the year 1849.

CASE. G. F., aged 37, a man presenting much hebetude of countenance, and evincing great sluggishness of manner and hesitation in his replies, gave a very unsatisfactory account of himself. The most we could make out was, that he had been for some time failing in his health and mental faculties; that he had had several convulsive fits; and that he had vomited frequently of late, though his appetite was keen and he was solicitous about his meals. When admitted, there was incomplete paralysis of the motor nerves in the lower extremities, sensation remaining. He passed urine involuntarily, though aware of the desire to do so. His bowels were obstinately constive; his tongue foul. He made no complaint of his head; but was inclined to be somnolent. These symptoms became gradually worse; and finally merged into fatal coma.

Autopsy. The convolutions of the brain were found to be flattened. There was more congestion than natural. There was an abundant effusion of serum into the ventricles, and the tunica arachnoidea at the base of the brain was thickened and opaque.

Here was a case of chronic meningitis, in which, so far as we know, there had been no delirium, though there had been considerable disturbance of the intellectual functions.

In 1850, two cases of meningitis came under treatment; one tubercular, the other simply inflammatory.

CASE. Mary Dyer, aged 22, had been ailing seven weeks; but the cerebral symptoms had only been developed about a week before her admission on June 21st. At this time she was in a state of half stupor, being incapable of answering questions, but not unconscious. The pulse was frequent; the tongue dry and brownish. The stools and urine were passed involuntarily. For some days, the symptoms seemed to belong as much to typhus fever as to a topical affection of the brain. On the 28th, however, the stupor became more decided, and was accompanied with strabismus and dilated pupils. The following day, there was drooping of the left eyelid, and the mouth appeared drawn to the right side. She died on the next day.

Autopsy. I am indebted to Dr. Ormerod for a most careful inspection of the brain, and for the following account of it. Much blood oozed from the vessels of the scalp. The arachnoid of the vertex was dry. On removing the brain, a good deal of fluid escaped from the spinal canal. The vertex of the left hemisphere, and the upper, outer, and anterior parts of the right, were of a deep greenish yellow colour. In some of these parts, the opposed surfaces of the arachnoid were adherent. The discoloured patches were interspersed with whitish granules; and all lay enclosed within the meshes of the pia mater. The same changes and adhesions were found anteriorly between the hemispheres; and about the base were many of the same whitish granules, besides older adhesions, without any greenish infiltrated fluid. The convolutions of the brain were distinctly flattened. The cerebral substance was generally firm, and free from disease. The septum, however, and the under surface of the fornix, were so softened, as to run into shreds. The lateral ventricles contained each about two-thirds of an ounce of reddish fluid, more stained in the right than in the

* This man died, as I have been informed, in the second week of January 1853, rather suddenly, having been affected with phthisis for four years, during all which time he had been taking cod-liver oil.

left. In a few points at the bottom of some of the convolutions, the yellow matter in the meshes of the pia mater shaded off gradually into the soft and discoloured cerebral matter; and round such points, the brain was intensely injected to the depth of three or four lines. There was no tubercle of the brain itself; but there was tuberculosis of other organs, the lungs and kidneys in particular, to some extent.

CASE. The other case of meningitis occurred in a girl aged 16. She had been ill a fortnight. We could get no history of the case: her friends, having consigned her to the nurse, departed, and the poor girl could give no account of herself. She lay on her back, shivering, with her knees drawn up. When touched, she screamed. There was complete ptosis of the right upper eyelid; the pupil of the right eye was greatly dilated, and insensible to light; the left also acted but sluggishly. The face was flushed, and hot; the pulse 146; the tongue coated. She passed urine and feces involuntarily. She died early the next morning.

Autopsy. On removing the calvaria, the arachnoid was found opaque, and covered in various places with flakes of coagulable lymph. There was but a small quantity of fluid in the ventricles. The substance of the brain appeared healthy. The pons Varolii was a little softened, particularly on the right side, beneath which part there was considerable effusion. Some recent adhesions were found between the anterior and middle lobes of the cerebrum. No tubercles were visible in any part of the brain, or of its membranes. The kidneys were highly congested: purulent matter could be squeezed from one. The uterus, also, was highly congested. The ovaries, and other organs, were healthy.

APOPLEXY. CASE. James Clements, a boy 9 years of age, was admitted, October 2nd, 1850, with incomplete hemiplegia of the left side. We had no opportunity of obtaining his history, till a week after his admission. His mother then reported, that he had always enjoyed good health till the middle of September, when he sometimes complained of headache, and that his left arm gave him pain when he moved it. At this time, she also observed that he limped in his gait. She said that he had never had fits, neither had he convulsions during dentition; that he had never received any injury of the head or back; and was not subject to worms. When admitted, he had recovered a good deal of power of motion in the affected limbs, but dragged the left foot in walking. Sensation had remained unaffected. There was no facial paralysis; his speech had never been altered. The pulse was 96; the tongue coated; the bowels constipated; the urine pale, alkaline, and of sp. gr. 1.016.

This seemingly slight and imperfect paralysis in a child, who made no complaint of his head, led me to hope that it might not have been caused by hæmorrhage, or tubercle of the brain. I therefore ordered mild mercurial alteratives and purgative medicines; and he improved under this treatment. On the 14th, he appeared better, and more cheerful than usual; but, about noon, whilst sitting on his bed, and talking with the patients, he suddenly complained of pain in his head. Vomiting soon came on, and was followed by purging. The breathing became embarrassed; and coma quickly supervened. Leeches were ordered to the temples, and a blister to the nape of the neck; but before these remedies could be applied, he died.

Autopsy, twenty-one hours after death. The membranes of the brain were much congested. On slicing the cerebral substance, numerous bloody points were seen; but nothing worthy of remark was discovered, till the brain had been removed from the skull, when, on its being placed base uppermost, a spot of effused blood became visible externally, being situated nearly in the centre of the pons Varolii, and seen through the membrane and unbroken cerebral substance enclosing it. On examination, there was a considerable recent effusion of dark blood, partly coagulated, and partly fluid, occupying chiefly the central portion of the pons, but extending into the right side. Upon narrower inspection, a second clot was found further to the right side: it was

white, and rather hard, as if of older date, and lay in a distinct cyst, with walls having a gelatinous aspect, which, upon examination with the microscope, were found to be composed of fibro-cellular tissue. Part of these walls appeared to have been torn by the recent hæmorrhage. The distinction between the first and the second clot was very striking. No disease of the neighbouring capillaries, or large vessels, could be made out. The heart was quite healthy. There were no tubercles in the lungs. A small calculus lay imbedded in the dilated pelvis of the right kidney.

This case is interesting and instructive. It is remarkable by reason of the infancy of the subject; of the seat of the hæmorrhage; of the partial and mild nature of the paralytic symptoms on the first occasion, and of their general distribution and rapidly fatal character on the last. It appears by the Registrar General's Reports, that out of a great number of cases of apoplexy at all ages, the deaths from 5 to 10 years are the least frequent of all. They appear to be not uncommon under 5 years of age, by the same Reports. Indeed, Messrs. Durnet and Tonellé have published some observations on apoplexy in infants from 1 to 5; this work is mentioned by Andral, but I have not seen it. From 10 to 20 years, deaths from sanguineous apoplexy are not infrequent. It may be stated in general terms, however, that Abercrombie, Rochoux, Copland, Lallemand, Andral, and Burrows, give no cases under 16. Andral, indeed, in speaking of the relative ages of subjects of apoplexy, says,* "One of the rarest forms of apoplexy, that affecting the cerebellum, has been seen in an infant 7 years old." But this case did not fall under his own observation, and is not included in 398 cases collected by him. Dr. West gives the case of a boy, aged 11, where extravasated blood was found in the right ventricle, with laceration of the substance of the brain; and Dr. Alexander Campbell† has reported the case of a boy of the same age (11 years), who died from sanguineous apoplexy; a clot being found in the middle lobe of the right hemisphere.

Dr. Richard Quain, in an able paper published in the *London Journal of Medicine* for January, 1849, gives the histories of two cases of apoplexy in children; one where blood was effused in the right hemisphere, occurring in a boy 9 years of age; the other in the arachnoid, in an unhealthy female child, aged 2 years and 7 months. He has also collected, from various sources, twenty-three cases of "meningeal hæmorrhage", and fourteen cases of "cerebral and ventricular hæmorrhage", in subjects of from 1 to 14 years of age.

But, besides the extreme youth of Clements, I would observe that the seat of the hæmorrhage is remarkable. I believe it to occur very rarely in that situation at any age. Abercrombie gives one case only in an adult. Solly quotes this case; and adds another from Ollivier, who refers to a few cases by Serres; but the other authors above named give no example of it. Dr. Craigie says that cerebral hæmorrhage, with respect to its relative frequency of situation, takes place in the following order: The corpora striata, thalami nervorum optico-rum, the hemispheres, pons Varolii, crura cerebri, medulla oblongata, and cerebellum. But hæmorrhage into the cerebellum appears, upon investigation, to occur more frequently than into the crura cerebri, pons Varolii, or medulla oblongata. Rokitsansky says, that the cerebellum is comparatively seldom the seat of hæmorrhage, and the pons yet more rarely. Its occurrence in the corpora quadrigemina, the pons, and medulla oblongata, is quite exceptional; and it almost never happens in the corpus callosum, the fornix, and the hippocampi. Occasionally, however, when a large cavity is formed in the cerebrum, one or more small secondary cavities are found also in other parts of the brain, especially in the cerebellum and the pons.‡ This author, however, in describing the healing process of cysts, observes, as if oblivious of the former statement, that in the pons, where,

* Med. Gaz. xvii, 539.

† Ibid. xxxvi. p. 172, abridged from *Northern Journal of Medicine*.

‡ Sydenham Society's Translation, vol. iii, p. 367.

on the whole, apoplexy is *not very rarely* observed, only very small cavities heal completely.*

Referring to the narrative of the case, we find that the paralytic symptoms at first were on the left side of the body, the old clot being afterwards found on the right; that the nerves of motion had alone suffered, sensation remaining entire; and that the power of motion remained longer impaired in the leg than in the arm. The head and neck were never in the least paralysed; intellect, speech, and deglutition, remained perfect. While in hospital, the patient made no complaint of pain till the day of his death. The seizure terminated very rapidly: first producing incapacity of motion, then stertorous breathing and coma. So long as the extravasation was of small extent, and confined to one side of the pons, the arm and leg of the opposite side of the body were alone affected, and that incompletely; but at last, when a more considerable effusion of blood took place, and probably pressed upon the medulla oblongata, then general paralysis, and a fatal interruption to the respiratory function quickly ensued. This order of sequence has been observed before.

In 1851, two cases of apoplexy occurred, in a man and woman, of the respective ages of 66 and 64. The former was attended with hemiplegia of the left side; the latter of the right. The man left in six weeks, having recovered a fair share of motion and sensation in the paralysed parts. The woman required longer treatment before she received the same benefit, perhaps owing to a more liberal abstraction of blood than was absolutely required. A third case, that of a woman aged 43, was also admitted, and was under treatment when these reports were drawn up. Here there was hesitation of speech, with paralysis of the right side. The spastic rigidity of the fingers, the convulsive movements, and the contractions of some of the flexor muscles of the affected side, led us to suspect softening of the brain.

CEREBRAL ABSCESS. CASE. George Elphick, aged 28, was admitted Nov. 21st, 1849. He had a cachectic appearance, and an expression of great suffering. He complained of very severe, constant headache, and frequent giddiness, which had lasted six weeks. He had been subject to attacks of asthma, on catching cold, as long as he could remember; and had been for three months suffering from cough, with difficult breathing, and an abundant muco-purulent expectoration of a greenish yellow colour and offensive odour. The chest, except at the upper part on the left side, was universally resonant on percussion, indicating emphysema. The respiration, however, was feeble, with sibilus and rhonchus generally diffused. At the upper part of the thorax, on the left side, corresponding to the apex of the left lung, there was dullness on percussion, and the voice was more resonant than natural. He had great thirst, and a white, moist tongue; the pulse was 84.

The pulmonary affection yielded to the treatment. The expectoration gradually diminished, till it ceased entirely, and with it the cough and all febrile symptoms. The head affection, however, proceeded with increased intensity. The right side, before and behind, was the seat of incessant pain. His respiration was now easy; his pulse fell below 50. He complained of constant nausea, but invariably took his food with appetite. He only got snatches of sleep, and was constrained to keep, as much as possible, an upright posture. A fortnight after his admission, his left arm and leg became slightly paralysed; but subsequently, together with an amelioration of all the symptoms, he recovered the use of both. His intellect, memory, and speech remained unaffected throughout his illness. On the morning of the 4th December, no particular change had been observed in him: he took his dinner as usual. In the afternoon, he became dull, heavy, and somnolent, and afterwards gradually comatose, in which state he expired towards night, having been in hospital about five weeks.

Autopsy forty hours after death. The following report was furnished by Dr. Ormerod:—

Weather mild and damp. The surface of the brain was bloodless. About the vertex, the convolutions were flattened. The brain being removed, and placed upon the table, the right hemisphere fell outwards. On a section of this hemisphere, there appeared three distinct abscesses in the posterior lobe, containing respectively 3iv, 3ij, and 3j of green and rather foetid pus; there were distinct cysts to the two smaller abscesses. The surrounding cerebral substance was softer than natural. Posteriorly, there lay two or three small, hard, round nodules, about the size of peas—yellow without, softened within. The bones and membranes were quite healthy. In the chest, both pleuræ were universally and toughly adherent. The front of each lung was very emphysematous. The right lung was nearly healthy, save a small number of nodules near the apex. The bronchi were congested, and full of bloody mucus and pus. In the left lung, the bronchi were similarly affected, and the hard nodules were very numerous, especially about the apex. Here the whole substance felt hard and heavy; but, on section, nothing particular was detected. Even on dividing these nodules, nothing was evident beyond a hard, somewhat transparent, whitish mass, like a cicatrix. There was no tubercle in the lungs or bronchial glands; and no ulceration of the bowels. This condition of lungs is accurately described by Rokitansky, who calls it chronic pneumonia.

This case presents several objects of interest and importance. The study of the diseases of the brain is beset with difficulties; great circumspection, therefore, is necessary in forming a diagnosis. In this instance we expected to find either tubercle or abscess, or both, in the substance of the brain on the right side; the pain having been seated there, and the hemiplegia having occurred on the left half of the body. But we rather leaned to the suspicion of tubercle, because we had regarded the consolidation at the apex of the left lung to have been caused by tuberculous deposit. In this opinion we erred, for it proved to be a rare form of pneumonia. During the whole illness, the intellectual faculties remained intact. Now, when the surface of the brain—that is, the neurine or cortical part thereof—or its investing membranes, are inflamed (and the one can hardly be inflamed without involving the other), delirium generally supervenes, and the intellectual faculties are always greatly disturbed. The remarkable exemption from disturbance of the intellect, therefore, had led us to attempt a localization of the disease in the medullary substance of the brain, apart from the surface or its membranes; and accordingly we found “the membranes healthy, and the surface bloodless.”

In this case, no convulsions occurred; and there were neither rigidity nor contractions, which usually happen in softening of the brain. Lallemand has hazarded the opinion, that when the sound hemisphere is not compressed by the disease going on in its fellow, it will carry on the intellectual functions, in the same way that one eye or ear would supply a loss of the other. He regards, in fact, the brain as a double organ, one half being capable of performing the office of both; thus anticipating the doctrine of the duality of the mind, propounded by Dr. Wigan.

PARALYSIS. In 1849, galvanism was employed with great success in a case of hysterical paralysis occurring in a girl of 18; and also afforded much benefit to a woman aged 45, affected with hemiplegia; but it failed to produce any relief in a man aged 33, who was under treatment for paralysis.

In December 1850, a married woman, aged 40, was admitted, with hemiplegia of the right side of some months' duration. She stated, that she was seized while in bed, and could neither speak nor move the right side. She appeared confused at first; and, though she articulated distinctly, her speech was abrupt and quick. Her tongue was protruded naturally. Motion in the arm and hand was lost: partially so in the leg. Sensation remained in both extremities, but was by no means normal. There was no facial paralysis. This case was seriously con-

* Ibid., p. 395.

plicated with epilepsy. The menses had been absent six months. The epileptic attacks occurred about once a fortnight or three weeks, and rendered the prognosis most unfavourable. A long issue was made in the sinciput, as recommended by the late Dr. Prichard. Under this treatment, she was much relieved; but the epileptic paroxysms continued to recur at the same intervals.

A case of hysterical paralysis, in a girl of 19, was under treatment for six weeks. She was cured by cupping, repeated blisters, and purgatives of aloes with compound galbanum pill. She was of a florid and plethoric habit.

In 1851, some cases of paralysis were admitted, without any manifest head symptoms. A woman, Fawcett, aged 40, had incomplete paralysis of the right side, chiefly of the arm and hand, complicated with epileptoid fits, not of a severe character. Though she did not complain of her head, an issue was inserted in the scalp with the best effect. The woman left the hospital free from fits, and remained so as long as she was under observation as an out-patient. The use of the hand and arm was quite restored.

Another case of partial paralysis occurred in a woman aged 47. The right side had chiefly suffered, but for the last twelvemonth the left leg had been slightly affected. She had never had a fit, but was subject to attacks of giddiness, and now and then of double vision. She laboured under prolapsus ani, as the consequence of a long-continued and severe hæmorrhoidal affection. The treatment was chiefly directed to the restoration of her general health, which was much impaired, and the relief of the local symptoms. We thought the paralytic symptoms were relieved by a strong infusion of the flowers of *arnica montana* and *valerian*. She left the hospital convalescent.

Two cases of paraplegia, connected with angular curvature, gave no encouragement to keep them long in hospital in hope of benefit; a third, in a girl nine years of age, got speedily well, by rest and a dose or two of purgative medicine; a fourth, if it were a case of paralysis at all, was hysterical; but there was reason to believe that the subject, a girl 20 years of age, was a malingerer. The application of the hot iron and galvanism soon restored the use of her legs.

CASE. In a child, Sarah Meads, aged 9 years, the symptoms led us to suspect disease of the cerebellum. She seemed unable to walk without constant risk of falling. There was a singular titubation in her gait. She had the use of her legs, but not the perfect command of them. She made no complaint of her head. There was no pain, tenderness, nor irregularity of the spine; no pain in moving the hips; no tenderness either before or behind the trochanters; no flattening of the nates; no shortening of either limb, nor any appreciable difference of size. She was of ordinary intelligence; fed well; and slept well. She was reported free from worms, but passed one large lumbricus during her stay in hospital, which was extended to eighty-five days. Internally, purgatives and vermifuge medicines were exhibited—zinc, iron, tincture of cantharides, iodide of potassium, etc.: externally we employed shower baths, stimulating liniments and blisters to the spine, and an issue in the nape of the neck. She left the house without any permanent amendment. She could walk better, but the crooked gait and want of balance in progression remained.

EPILEPSY. In 1849, two cases occurred: one, from uterine disease; the other, according to the report, from worms.

CASE. — Marsh, aged 18, a fat, pale girl, of fair complexion, had been subject to epileptic attacks for a twelvemonth, either directly before or after the menstrual period. The catamenia were profuse, recurring every fortnight, and sometimes flowing unceasingly for a fortnight or three weeks. She complained of headache and palpitations. Each attack of epilepsy was preceded by an aura, beginning at the left knee, and ascending gradually to her chest, when she lost her consciousness. She was seen in one well marked fit after her admission, but never afterwards. The case was treated with infusion of digitalis,

beginning with a dose of 3ij, and gradually augmenting it to ʒiiss daily. Whilst taking the medicine, during a period of three months, she occasionally complained of vertigo and headache, but scarcely more than she had been liable to before. The pulse ranged from 72 to 100, and was slower at the commencement than at the end of the treatment.

In the other case, a girl 9 years of age, no fit took place in the house. She was smartly purged with calomel and jalap, and took sesquichloride of iron in infusion of quassia. Though she was reported to have worms, none were evacuated.

In 1851, the following case was admitted:—A farm labourer, 42 years of age, had been for nine years subject to epileptoid fits, in which he was insensible, but never violently convulsed. He had never bitten his tongue, and had never been observed to foam at the mouth. The fits occurred at irregular intervals, at night, generally in his sleep. He had a vacant countenance, and was rather deficient in intelligence. He had suffered from ague on three several occasions; the last being a month before admission. Turpentine, administered internally, did good for a time; then henbane and camphor. Moderate cupping and blistering relieved any weight or pain about the head. I prescribed the cotyledon umbilicus, which I have found very useful in several cases of epilepsy; but it did not receive a fair trial, as he soon left the hospital by his own desire.

DELIRIUM TREMENS. In 1849, two cases occurred, in which chloroform was administered by inhalation, with satisfactory results.

In 1850, a man died of delirium tremens, with typhoid symptoms. He was found to have a very large, fatty liver, which descended to the umbilicus, and spread laterally into the left hypochondrium. It weighed between six and seven pounds. Its inferior edges were flattened and thin; its upper surface was rounded. Its colour throughout was a faded yellow, like that of dried leaves. When it was bruised, a greasy mark was left on the scalpel. Oil-globules were found, on examination with the microscope. The gall bladder contained a notable quantity of bile, of the usual appearance. The spleen was of a loose, friable texture. The kidneys were healthy.

In 1851, one case of delirium tremens occurred in an elderly man, who, besides being addicted to spirits, took a great deal of laudanum. He was very noisy, and had had no sleep for five nights. His evacuations escaped involuntarily. The house-surgeon gave him immediately a drachm of laudanum in a pint of porter. He also ordered a pill, containing five grains of extract of hyoscyamus with one grain of opium, to be taken every second hour. The man took two pills, slept five hours, and soon recovered.

CHOREA. In 1850, two severe cases of chorea were admitted.

CASE. — Dale, a boy 10 years of age, had had rheumatic fever about three months previous to the attack. There was a slight but decided systolic murmur. He remained but a short time in the house, and was made an out-patient. Both sides of the body were affected, and he lost his speech; deglutition also became difficult. The shower-bath could not be persevered in, on account of the child's terror and resistance. He got well under the use of sulphate of zinc, in doses of from two to three grains, with extract of valerian and Barbadoes aloes.

CASE. James Mitchell, aged 12, was seized with chorea two months before admission, after an illness which, from the description, was probably rheumatic fever. There was no systolic or other murmur in the heart or vessels. This boy, in all his movements, whether of the head, trunk, or extremities, exhibited the most fantastic and ludicrous attitudes; but it was frightful to see him go down stairs, which, I understand, he contrived to do without ever meeting with an accident. The shower-bath, purgatives, oxide of iron, and sulphate of zinc, with valerian and Barbadoes aloes, were successively tried for two months—with benefit to his general health, it is true, but with very little effect upon

the convulsive movements. The liquor potassæ arsenitis was then administered, in doses of two minims three times a day. The improvement was marked and speedy. He was discharged, fat and in good health, in one month after this medicine was begun.

In 1851, three cases of chorea came under observation.

CASE. A youth, 20 years of age, was affected with involuntary twitchings and irregular movements of the left side of the body. His speech was hesitating, and he had occasional strabismus. These symptoms had existed for four months, as a sequence of rheumatic fever. This was the second attack of rheumatic fever. The first, a more severe one, had occurred ten years before, and affected all his joints. No abnormal condition of the heart could be detected. He was discharged well at the end of a month. The shower-bath was employed; and he took black oxyde of iron with Barbadoes aloes, which kept up a brisk action upon the bowels.

CASE. Reuben Weller, aged 12 years, had been affected for six months with chorea, succeeding to catarrh and severe rheumatic pains. He had great difficulty in articulation. Any attempt at voluntary motion was followed by the wildest contortions and the most ludicrous attitudes and grimaces. His sleep was sound, without any convulsive twitchings. Both sides of the body were affected: the left most so. The pulse was 67, regular. He took two minims of liquor potassæ arsenitis three times a day. The convulsions soon yielded to this remedy. In three weeks, he had recovered the command of the voluntary muscles, and he had improved in flesh, strength, and spirits.

CASE. Fanny Dowden, aged 10, a fair, weakly child, of nervous temperament, was admitted with chorea. This was the second attack; the first happened two years previously, and lasted six months. Both attacks were suddenly brought on by fright; the present one commenced three weeks ago. She had been troubled for some time with ascarides. Her face was only slightly affected; the speech not at all so. Her gait was very unsteady. Both arms were violently tossed about, if she attempted to use them. Her sleep was very unquiet, with frequent moanings. After the worms had been removed by purgatives and turpentine injections, the black oxyd of iron and the shower-bath were ordered. The latter being relinquished in consequence of the terror it inspired, and the former availing nothing after a month's trial, we gave from one to two minims of liquor potassæ arsenitis three times a day. In one week, improvement was manifest; in three weeks she was quite well, her general health being much amended.

NEURALGIA. In 1849, all the cases of neuralgia, with one exception—a man aged 61, who had facial neuralgia from diseased teeth—occurred in young females. In two instances, the trifacial nerve was affected; in the rest, five in number, the intercostal nerves were the seat of pain: on the left side in four, and on the right in one. Neuralgia of the intercostal nerves likewise occurred in two hysterical cases; and a severe attack of *tic douloureux* of the right side of the face happened to a girl who was admitted with peritonitis. All the cases of intercostal neuralgia, save one, were affected on the left side below the breast. In this situation, the pain, though great, never equalled in severity that of the face, where it reached a degree which Cotugno expressively calls *fulgura doloris*. The mode of treatment was adapted to the condition of the patients, according to the signs of congestion or anæmia, gastric or uterine disturbance, rheumatic or scrofulous diathesis, etc.; and consisted of local bleeding, derivatives, counter-irritants, purgatives, alteratives, tonics, and narcotics, singly or in combination, according to circumstances.

In 1850, the topical application of the hot iron, as recommended by Dr. Day, was generally attended with much benefit.

In 1851, an inveterate case of intercostal neuralgia, in a young woman who was labouring under leucorrhœa of long standing, and obstinate costiveness, began to yield to arsenic after the fruitless employment of purgatives, zinc, quinine,

iron, aconite, henbane, belladonna, the hot iron, and various injections. She, however, now left the hospital to go into the country.

Another woman, with a host of anomalous symptoms, and pains everywhere, who had been in hospital five times before, left it for the sixth time, apparently in very good condition; but, as she averred, not a whit benefited.

HYSTERIA. Among the cases of this description in 1850, was one of aponia, one of singultus, and one of hæmatemesis. The first and second got well after a brisk succession of local and internal remedies: the third deserves a more detailed notice.

CASE. Mary Childs, aged 19, a stolid-looking girl, short and fat, had been ailing six months, during three of which the catamenia had been suppressed, though she reported that she had never been regular. Her prominent symptom was vomiting of a bloody mucus, every day, about half-past seven in the evening; after which, pain of the stomach and head, of which she complained, became easier. Our suspicions were very early excited as to the truth of her statements, for no portions of food were ever detected in the fluid said to be vomited: nevertheless, the fact of the amenorrhœa, which had been ascertained, gave an air of probability to her tale. Not being able to come to any satisfactory conclusion as to the source of the hæmorrhage from mere inspection, I requested Mr. Hodgson to submit it to the microscope. He found abundant pavement epithelium belonging to the mouth, and a total absence of the columnar epithelium proper to the stomach. She was watched, and detected in sucking her gums. Of course, after this the hæmorrhage ceased, and she was dismissed.

[To be continued.]

ON THE MEDICO-LEGAL SIGNIFICATION OF CLOSURE OF THE FORAMEN OVALE, AS A SIGN THAT A CHILD HAS BEEN BORN ALIVE.

By CHARLES KIDD, M.D.

A FEW remarks on the question of closure of the *foramen ovale*, as a sign that a child has been born alive, may prove of interest. I will first relate a case which came under my observation, and which was the subject of a trial.

CASE. A young woman, a barmaid at a tavern, had contracted an intimacy with a young man in her own sphere of life, under the promise of marriage; she continued in her situation, even under the watchful eye of her mistress, who gave evidence in the case, up to the day on which the child was born—about three weeks before the time when it was found. The night before her confinement, it appeared in evidence, she went to bed as usual with her fellow-servant at about twelve o'clock. At two o'clock in the morning she awakened the latter, complaining of pain in the bowels, and sent for her mistress, who prescribed something hot, and went to bed again. Her fellow-servant stated that she was tired, and went to sleep. At about four o'clock, the child, to her utter dismay, was born. She had presence of mind enough to know that, if the child were discovered at six o'clock, when the inmates of the house were usually stirring, she would lose her place, and be disgraced. She accordingly wrapped the child in a rough towel, and, descending two flights of stairs, hid it in an unoccupied cellar. She left the service next day, with her mother, and went to reside in one of the suburbs of London. The child evidently died of cold and neglect in a few hours after having been placed in the cellar; for, if it had cried or made any noise, it could not have failed to be discovered.

On making a *post-mortem* examination, the child was found in a rather good state of preservation: it appeared to have been born at the eighth month. The lungs shewed somewhat equivocal signs that respiration had taken place: they floated in water, but not very buoyantly. In the heart was found a thick layer of lymph thrown across the foramen ovale, which was all but blocked up; and the obliteration of the ductus arteriosus had already been completed. The placenta was attached to the infant: whether this may have tended to keep up strong vital action in the child independently of the mother, might form a subject for speculation. In three other *post mortem* examinations of infants, which came under my notice about the same period, the signs of respiration were much less doubtful, and the children had apparently lived some time; yet there was not even the most imperfect attempt, in any of them, either at closure of the ductus arteriosus, or obliteration of the foramen in the auricular septum.

REMARKS. The complete closure of the ductus arteriosus, and the formation of a nearly complete septum across the foramen ovale, are proofs of the fallacy of the commonly received dicta of authors, who tell us that the former becomes obliterated from the sixth to the twelfth day, while the time of closure of the latter is less certain. Billard says, that the foramen is closed between the second and third day; but Dr. Handyside states that it remains more or less unclosed for life in one case out of eight. Dr. Taylor also, in his work on *Medical Jurisprudence* (4th edition, p. 403), observes, that he "has frequently found the foramen ovale open in children who had survived birth several hours." Again: the foramen ovale may become closed before birth, in consequence of intra-uterine inflammation, or some abnormal condition. Dr. Taylor refers to this subject. He says: "The closure of the foramen ovale has been known to occur as an abnormal condition previously to birth and the performance of respiration. One case is mentioned by Capuron (*Médecine Légale des Accouchemens*, p. 337); and another, of a very instructive kind, is reported in the *Medical Gazette* (vol. xxxviii, p. 1076). Other instances of this abnormal condition are adverted to by Dr. Chevers (*Med. Gaz.*, vol. xxxviii, p. 967), and it would appear that in these the arterial duct remained open, in order to allow of the circulation of blood, not only before, but subsequently to respiration. The children rarely survive birth longer than from twenty to thirty hours. Dr. Chevers justly remarks, that 'Cases of this description are of the highest importance in a medico-legal point of view, as they fully disprove the opinion maintained by many anatomists, that obliteration of the foramen ovale must be received as a certain evidence that respiration has been established.' It would, therefore, be unsafe in practice to rely upon the closure of this aperture as proof of live birth, without other good evidence: and in no case can its patency be regarded as a proof that a child has come into the world dead." (p. 404.)

With regard to the ductus arteriosus, the observations of Dr. Chevers, referred to by Dr. Taylor (*op. cit.* p. 400), go far to point out the fallacy of depending on its condition as a test of the child having lived. This passage may be closed before birth; and it has even been found, when there was strong reason to believe that the child had not survived birth more than ten minutes, in as advanced a stage of closure as if it had been born some days.

It would be beyond the scope of this paper to discuss the other signs of live-birth, as the floating of the lungs, signs derived from the umbilical cord, etc.; but my object has been to draw attention to the fallacy of placing too much confidence in the dicta found in many medico-legal works, and to point out how far our most modern authorities are disposed to trust to the closure of the foramen ovale and ductus arteriosus, as signs that a child has been born alive.

Kingland, January 1853.

THE HOUR OF BIRTH IN 2019 CASES.

By R. U. WEST, Esq.

It is generally understood that accoucheurs have "plenty of night-work"; but I am not aware that any one has attempted to show in what proportion the night-work preponderates.

		First set of 700.	Second set of 700.	Third set of 619.	Total 2019.
8 hours of night.	P.M. 11—12	42	33	37	= 112
	A.M. 12—1	25	23	16	= 64
	1—2	43	28	28	= 99
	2—3	40	37	26	= 103
	3—4	30	50	24	= 104
	4—5	29	34	25	= 88
	5—6	33	37	40	= 110
	6—7	33	37	30	= 100
	Total . .	275	279	226	= 780
8 hours of day.	A.M. 7—8	27	31	28	= 86
	8—9	29	20	32	= 91
	9—10	18	29	33	= 80
	10—11	37	29	33	= 99
	11—12	31	31	26	= 88
	P.M. 12—1	26	28	21	= 75
	1—2	25	26	23	= 74
	2—3	26	24	19	= 69
	Total . .	219	228	215	= 662
8 hours of evening.	P.M. 3—4	22	25	23	= 70
	4—5	25	17	17	= 59
	5—6	18	26	12	= 56
	6—7	20	20	28	= 68
	7—8	30	20	31	= 81
	8—9	33	27	22	= 82
	9—10	28	28	23	= 79
	10—11	30	30	22	= 82
	Total . .	206	193	178	= 577

The statistics here given shew the hour of birth in 2019 cases which I have attended, and they certainly bear out the popular idea on the subject. In order to prove that the proportions given are not accidental, I have divided the total number of cases into three nearly equal sets of 700, 700, and 619, from which it will be seen that, although there may be some discrepancy when single hours are taken, yet the gross number in each period of eight hours presents a remarkable uniformity. It will readily be understood that these tables give only part of the truth, for some of the births which took place in the earlier hours of the *second* eight hours—"the eight hours of day"—must have involved an *attendance* breaking into the night-hours. Consequently, the eight hours when the smallest number of births took place,—viz., those of "the evening",—were those least likely to require night-watching.

Alford, Lincolnshire, Jan. 29th, 1853.

ARSENICAL CONFECTIONARY. An inquest was lately held at Ashford, upon two brothers killed by eating the painted ornaments of a Twelfth cake. Professor Taylor, who analyzed the stomachs of the deceased children, said that he had detected arsenic. The quantity discovered did not exceed a quarter of a grain. The yellow colour of the ornaments was produced by orpiment, or sulphuret of arsenic. The green colour of the ornaments was imparted by the arsenite of copper, which is very poisonous even in minute doses. During the two last years Dr. Taylor had met with ten fatal cases from children eating these ornaments.

BIBLIOGRAPHICAL NOTICES.

REPORT TO THE HOUSE OF REPRESENTATIVES OF THE UNITED STATES OF AMERICA, vindicating the Rights of CHARLES T. JACKSON to the Discovery of the Anæsthetic Effects of Ether Vapour, and disproving the Claims of W. T. G. MORTON to that Discovery. Presented to the House of Representatives of the United States, on the 28th of August, 1852, by Hon. EDWARD STANLY, of North Carolina, and Hon. ALEXANDER EVANS, of Maryland, Members of the Select Committee on the Ether Discovery. Printed by Authority of the Minority of the Committee. 8vo., pp. 57.

THE nature and object of this publication are sufficiently indicated by the title-page. In this country, the chief merit of originating the discovery of etherisation seems to be thought by those who have taken the trouble to weigh the evidence, to belong to Mr. MORTON. Such at least is the award of a high authority, whose work lies before us at the moment; and the reader will likewise find it sustained at the commencement of an admirable review of the whole subject of anæsthesia and anæsthetic agents, in the British and Foreign Medico-Chirurgical Review, in 1852. The present authors however—or rather we should employ the singular number, for Mr. EVANS merely contributes a brief notice of his approval at the end—the present author then, takes up the cudgels manfully in behalf of Dr. JACKSON. Shortly after the discovery was promulgated to the world, Mr. Morton presented a memorial to Congress, praying, in a consideration of its use by the army and navy of the United States, for an appropriation of money from the treasury. The application was resisted by Dr. JACKSON, on the ground that he, Dr. JACKSON, was the real author of the discovery. On this, the matter was inquired into by a select committee of five, whereof a majority of three came to the conclusion, that Mr. Morton was the rightful claimant. The minority, however, strongly persuaded of the injustice of this decision, now come forward with a powerful exposition of their reasons for dissenting from their colleagues; showing that the preliminary training and after pursuits of Dr. JACKSON were of a kind peculiarly calculated to qualify him both for conceiving the idea and nursing it to maturity; giving us his account of the circumstances which led him to try the ether on his own person, and of the success of the experiment; and producing testimonials from eight individuals, to the purport that he had made them acquainted with the anæsthetic properties of ether at different periods between 1841 and 1846, the latter being the date at which they were brought into prominent notice. Further on, we come to a “verdict” of what is termed a “jury of the vicinage”, consisting of a host of medical men resident in Massachusetts, who testify to the high character of Dr. JACKSON, and assert their belief that to him alone any honours or rewards that Congress may think proper to bestow, are exclusively due, so far as the great fact of discovery is concerned. To this is subjoined a similar manifestation of opinion on the part of thirty-seven members of the Massachusetts Medical Society. Our countryman, Sir C. LYELL, is shown to take the same view of the question in a letter to Dr. JACKSON, where he expresses his surprise at the insignificance of the rival pretensions. On the other hand, Mr. Morton is charged with having wrongly represented the decision of the majority of the Committee of Congress as emanating from that body collectively; and of enlarging the apparent size of a medal awarded him by the French Academy, with a view of giving it a higher significance than was really intended; his great object being to turn the discovery to a profitable account.

It must be admitted, that the minority have put forward a strong case for their client, and one which at least makes it incumbent on the public to suspend its final judgment, until after hearing any reply that may be forthcoming from the opposite party. The question is one of no inconsiderable interest. Not only are we bound in common gratitude to render honour where it is due, for so benefi-

cent a gift to suffering humanity; but recent experience also brings to mind how eagerly those passages in the history of distinguished men are sought out, which expose their inner life, and show by what circumstances and tendencies they were conducted to the achievements which excite our wonder and admiration.

The circumstances which immediately led Dr. JACKSON to make a trial of ether, are stated as follows in his own words:—

“Having been appointed geologist and chemist to the State of Maine in 1836, I opened a large chemical laboratory, the next year, for instructing my pupils, and for making the chemical analyses for the State, and had frequent occasion to experiment with chlorine gas, and had accidents to myself, as well as to my pupils, by the breakage of vessels filled with this gas. Vapour of alcohol was at that time the remedy we used for relief, and, not finding it to answer the purpose satisfactorily, I soon after tried the inhalation of sulphuric ether vapour, which from 1837 to 1841, was the means in habitual use in my laboratory for relieving persons from the effect of the action of chlorine in the lungs.

“In the winter of 1841-42, I made the discovery of anæsthesia by ether vapour.

“The circumstances were as follows:—In the winter of 1841-42, I was employed to give a few lectures before the Mechanics’ Charitable Association in Boston: and in my last lecture, which I think was in the month of February, I had occasion to show a number of experiments in illustration of the theory of volcanic eruptions, and for my experiments I prepared a large quantity of chlorine gas, collecting it in gallon glass jars over boiling water. Just as one of these large jars was filled with chlorine, it overturned and broke, and, in my endeavours to save the vessel, I accidentally got my lungs full of chlorine gas, which nearly suffocated me, so that my life was in imminent danger. I immediately had ether and ammonia brought to me, and alternately inhaled them with great relief.

“The next morning my throat was severely inflamed and very painful, and I perceived a distinct flavour of chlorine in my breath, and my lungs were still much oppressed. I determined, therefore, to make a thorough trial of the ether vapour, and for that purpose went into my laboratory which adjoins my house in Somerset Street, and made the experiment, from which the discovery of anæsthesia was deduced. I had a large supply of perfectly pure-washed sulphuric ether, which was prepared in the laboratory of my friend, Mr. John H. Blake, of Boston. I took a bottle of that ether and a folded towel, and seated myself in a rocking-chair, placing my feet in another chair, so as to secure a fixed position as I reclined backward in the one in which I was seated. Soaking the towel in the ether, I placed it over my nose and mouth, so as to inhale the ether mixed with the air, and began to inhale the vapour deeply into my lungs. At first the ether made me cough, but soon that irritability ceased, and I noticed a sense of coolness, followed by warmth, fullness of the head and chest, with giddiness and exhilaration. Numbness of the feet and legs followed, and a swimming or floating sensation as if afloat in the air. This was accompanied with entire loss of feeling, even of contact with the chair in which I was seated. I noticed that all pain had ceased in my throat, and the sensations which I had were of the most agreeable kind. Much pleased and excited, I continued the inhalation of the ether vapour, and soon fell into a dreamy state, and then became unconscious of all surrounding things. I know not how long I remained in that state, but suppose it could not be less than a quarter of an hour, judging from the degree of dryness of the cloth, which, during this state of unconsciousness, had fallen from my mouth and nose and lay upon my breast. As I became conscious, I observed still there was no feeling of pain in my throat, and my limbs were still deeply benumbed, as if the nerves of sensation were fully paralyzed. A strange thrilling now began to be felt along the spine, but it was not in any way disagreeable; little by little sensation began to manifest itself, first in the throat and body, and gradually extended to the extremities, but it was some time before full sensation returned, and my throat became really painful.

“Reflecting upon these phenomena, the idea flashed into my mind that I had made the discovery I had been for so long a time in quest of,—a means of rendering the nerves of sensation temporarily insensible to pain, so as to admit the performance of a surgical operation on an individual without his suffering pain therefrom.” (pp. 5-6.)

It is alleged, that Mr. Morton not only obtained his

knowledge of the anæsthetic effects of ether from Dr. Jackson, but at the time of the communication was completely innocent of any acquaintance even with the existence or the very name of such a substance. Here is an account, attested on oath, of a curious, and, as it proved, momentous interview, which took place in the latter gentleman's laboratory; a second witness also describing the scene in equivalent terms:—

"I, George O. Barnes, of Plymouth, in the Commonwealth of Massachusetts, depose and say, that in the fall of 1846 I was a student in chemistry with Dr. Charles T. Jackson; that in the month of September I was at work in the back room of Dr. Jackson's laboratory, when Mr. W. T. G. Morton passed through the room, as I supposed to go into the house, which adjoins the laboratory. He soon returned, having in his hand an India-rubber bag belonging to Dr. Jackson. As he went into the apparatus or glass-room, I heard Dr. Jackson ask Morton what he wanted to do with the bag. He replied that he had a refractory patient, who would not allow him to take out her tooth, and that he wished to act on her imagination, so as to induce her to submit to the operation; that he meant to fill the bag with air, meaning, as I understood, atmospheric air, which would give it a formidable appearance. He then asked how he should go to work to distend the bag. 'The lungs or a pair of bellows,' said Dr. Jackson, 'can do that.' 'But,' continued Dr. Jackson, 'your proposition, Morton, is very absurd; the patient will not be deceived in that way; you will produce no result, and will be denounced as an impostor.' 'I don't know that,' replied Morton; 'I think, with this bag under my arm, well blown up, that I could make her believe anything.' While saying this, he placed the bag under his arm, and, pressing the bag with his elbow several times, illustrated the manner in which he would operate. 'If I could once get her mouth open,' said Morton, 'I would have her tooth out. Why,' said he, 'a man once bled to death by the mere force of imagination.' As he was proceeding to give an account of this experiment, Dr. Jackson interrupted him, and said, 'Pooh! you don't credit such a story as that, surely! I advise you to have nothing to do with this idea of using atmospheric air to deceive your patients; it will only injure you.' Morton replied, 'I don't care. I'll blow it up.' Morton then left Dr. Jackson, and was going from the glass-room, where the latter part of the conversation had been principally held, into the front room towards the street door, with the bag swinging in his hand, when Dr. Jackson followed him, took the bag from his hand and threw it on the floor. There had been also some conversation concerning nitrous oxide, but not one word concerning sulphuric ether; and Morton had not asked Dr. Jackson to suggest to him anything to prevent pain during his operations of extracting teeth. Dr. Jackson then addressed him, and said, 'Now, Morton, I can tell you something that will produce a real effect. Go to Mr. Burnett's, the apothecary, and get some very strong sulphuric ether,—the stronger the better,—spatter it on your handkerchief, put it to your patient's mouth, take care that it be well inhaled, and in a minute or two perfect insensibility will be produced.' 'Sulphuric ether!' said Morton, 'what is that? Is it a gas? Have you got any of it? Show it to me.' Dr. Jackson went to the laboratory case, and took down the bottle of sulphuric ether, which Morton examined, and smelt of as though he had never seen the article before, saying it was 'queer-smelling stuff.' 'Are you sure,' said Morton, 'that this will do it?' 'Yes,' replied Dr. Jackson, 'I am sure.' * * * *

"Either on the afternoon of the same day, or the next day, I am not positive which, Morton came to announce the success of his trial. He stated that he tried it on a patient with complete success; for, while he extracted a tooth, the person was insensible, and knew nothing about it. Dr. Jackson expressed no surprise, but appeared as if he had expected this result. Mr. Morton intended soon to perform another extraction. Dr. Jackson then said to him, 'You must go to Dr. Warren, and obtain his permission to administer it at the Massachusetts General Hospital, and if possible it should be in a capital operation; for the people will not believe in the insensibility to pain in case of a mere tooth, since it is very common for patients, in an ordinary case, to say that it did not hurt them, when the twitch is very sudden, and the operation skillfully performed; this proof would not be regarded by the public as satisfactory.' Morton strongly objected at first to going to the hospital; that everybody could smell the ether, and it would not be kept secret, which it was Morton's object to do. He asked if something could not be put into it which would conceal the ether odour. Dr. Jackson replied, 'Yes; some French essence, as the oil of

Neroli, may answer in a measure, and a pleasant perfume will be left on the patient;' remarking, laughingly, 'the scent of the roses will hang round him still.' After some argument, and Dr. Jackson's further insisting upon it, Morton promised to go to the hospital." (pp. 20-21.)

We have rather overstepped our limits in giving the above extracts, because they appear to contain the pith of the whole controversy. Supposing the authenticity of these statements to be unassailable,* we do not see how any one can object to the conclusion of the members of the Massachusetts Medical Society, "that, in relation to the great discovery of etherisation, Dr. Jackson was *the head*, and W. T. G. Morton *the hand*"; unless, perhaps, on the score of its being too favourable to the latter gentleman. We should rather compare them to the inventor who discovers and applies, and the workman who imitates; to the physician who recommends a new remedy, after first satisfactorily testing its safety and efficiency, and his professional brother who adopts it and finds it to answer in his own experience.

OBSERVATIONS AND REPORTS ON THE TREATMENT OF INTERMITTENT FEVER BY PHOSPHATE OF LIME AND SULPHUR. By A. BLACKLOCK, Esq., Assistant-Surgeon, Madras Army: with Cases by J. ANDERSON, M.D., and JOHN DREVER, Esq. 8vo. pp. 103. Madras: 1852.

WE have here a novel theory of the cause of fever; and a new mode of treatment founded on that theory. Mr. BLACKLOCK says: "The whole train of reasoning in the present paper is founded on observations which have led to the belief that loss of phosphates from disintegration of nervous tissue, or their deficiency in the circulating fluid, is a predisposing cause of fever." His argument proceeds in this way:—There are two acids in the nervous tissue, the *cerebric* and the *oleophosphoric*, the deficiency of either of which is likely to be followed by constitutional disturbance; the former is most abundant in the sympathetic ganglia and the grey matter, while the latter is most abundant in the white nervous substance. Quinine, which most resembles cerebric acid, has been found most useful in those fevers which appear to have their origin in some defect of the constitution of the nerves of organic life; but cases are frequently met with where there is no decided derangement of important organs, and which yet experience little or no relief from quinine. The author is here led to the belief that *phosphate of lime* will make good the deficiency most frequently leading to fevers among the natives of India. He thinks it time to inquire, whether there may not be two classes of cases, one requiring alkaloid remedies, the other earthy phosphates.

The primary cause of intermittent and remittent fever, he has been led to consider to be "a loss of balance between the nervous tissue and the other soft tissues of the body, ascribable, in a large proportion of cases, to a deficiency of phosphates in the nervous matter." He first tried phosphate of lime and magnesia on himself, as he was passing large quantities of phosphates in his urine; but with only temporary relief. On combining it, however, with sulphur, he found the phosphate to be retained in the system. Mr. Blacklock then proceeded to administer the medicine to soldiers of the Madras army, labouring under intermittent fever, with, according to his account, highly favourable results. The phosphate of lime, most easily obtained by calcining sheep's bones, is mixed with one-sixth of its weight of sublimed sulphur. The dose is two drachms, thrice a day, in treacle or in sugar and water.

"It should be continued steadily till the usual period for the

* The "minority", we should observe, do not quite clear up the difficulty occasioned by a statement of Mr. Horace Wells, who relates, that having tried the nitrous oxide on himself, while having a tooth extracted, and in several other cases, with success, in 1844, he mentioned the results to Drs. Warren, Hayward, Jackson, and Morton, "the last of whom expressed themselves in the disbelief that surgical operations could be performed without pain—both admitting that this *modus operandi* was quite new to them—and these, he says, are the individuals who now claim the discovery."—*A History of the Application of Nitrous Oxide Gas, Ether, and other Vapours, to Surgical Operations.* By Horace Wells. Hartford, 1847.

expected fever has passed without any febrile return. Four drachms may be given at the first, if the patient be very weak when first seen, or if there be any urgent necessity for at once cutting short the fever. Half a drachm thrice a day, is considered a suitable dose between the ages of two and five; one drachm from five to twelve; and after that age, two drachms thrice a day."

Dr. ANDERSON, after giving the reports of fifteen cases of uncomplicated intermittent fever, thus expresses his opinion on the merits of Mr. Blacklock's remedy.

"So many slight cases of ague recover without any treatment, or after one emetic or purgative, and the failure of the remedy in the remaining seven cases was so signal, and contrasted so strongly with the effect of the bark or quinine, which had eventually to be employed to prevent the return of the paroxysms, that I suspect Mr. B.'s powder possesses very feeble antiperiodic powers. Many slight cases of intermittent fever will, I doubt not, recover under its use; and as it is a cheap remedy, it deserves a further trial, especially in the cases of natives, to whom Mr. B. has given it most extensively and successfully."

We have thought it right to bring before the notice of our readers the novelties contained in Mr. Blacklock's pamphlet; but we hope that the fact of our having done so will not be regarded as any evidence of our adopting them as truths or real discoveries.

REMARKS ON THE EXTERNAL APPLICATION OF IODINE IN ERYSIPELAS, with Suggestions for its Use in PUERPERAL FEVER. By HUGH NORRIS, Surgeon. Pamphlet. pp. 12. South Petherton, Somerset: 1853.

THIS is a reprint from the *Medical Times and Gazette* for 11th December, 1852, of a paper read by Mr. NORRIS before the Crewkerne and Yeovil Medical Association. He first speaks of the local application of iodine in erysipelas, and then treats of its use in puerperal fever.

In erysipelas, the author has, for four years, applied the tincture of iodine in nearly thirty cases of idiopathic erysipelas, with a favourable result in all. Its *modus operandi*, he is inclined to believe, is as much constitutional as local. Mr. Norris does not claim priority, but refers to a pamphlet published some years ago by Dr. Davies, of Hertford, *On the Use of Iodine locally applied*. He has not, except in very mild cases, depended solely on the iodine; but has given salines, or wine and tonics, according to the necessities of each case.

In puerperal fever, Mr. Norris, inclining to the doctrine of the erysipeloid nature of the disease, submits, that the "very early and free application of the tincture of iodine, or rather, of a *pigmentum iodinii*, much stronger than the pharmacopœia tincture, over the whole surface of the abdomen, might prove of service". He and some of his medical friends have tried this remedy in several severe cases, with low peritonitis, great tympanitis, exhausting diarrhoea, suppression of the renal discharges, and a tendency to death by asthenia. The rational internal treatment was employed at the same time.

"The immediate effects of the iodine application were manifest relief to the peritoneal tenderness, and rapid subsidence of the tympanitis, and in the cases I attended, at least, such comfort followed its use, and so sensible were the patients of the benefit it appeared to occasion, that, although productive of extreme pain at the time of application, they would again and again beg me to repeat it, 'because it did them so much good'."

In conclusion, Mr. Norris believes he has at least adduced strong reasons for giving the local application of a solution of iodine a full and extended trial in puerperal peritonitis; for he has shown in his own practice—

"1. That a very free and oft-repeated application of a strong pigmentum iodinii over the whole abdomen, in the low peritonitic form of puerperal fever, is not injurious. 2. That, as a counter-irritant, at least, it is actually beneficial. 3. That we have good reason, from analogy, to hope it may possibly in some cases be found to exercise an influence *sui generis* over the peculiar kind of inflammation, with which we have to deal in treating the worst forms of puerperal fever."

PERISCOPIC REVIEW.

BOTANY.

CELLULOSE COMMON TO ANIMALS AND PLANTS: RELATIONS OF THE VOLVOCINEÆ.

As regards the analogies between animal and vegetable structure, one of the most interesting discoveries of late years, is, that cellulose is not confined entirely to plants. The researches of Külliker, Löwig, and Schmidt, have shown that the mantle of many ascidians contain cellulose. Schacht states that in phallusia (one of the ascidians) it constitutes the intercellular substance, but does not, as in the plant, form part of the cell-wall itself; while in *cyathia*, and some other ascidians, the cellulose forms free fibres. The observations of SIEBOLD, WILLIAMSON, COHN, and BUSK, have led to the conclusion that the family of the volvocineæ is to be considered as vegetable and not animal. These authors have determined that their structure, their mode of reproduction, and the existence of zoospores (moving spores), with vibratile cilia, shew their alliance to many of the algæ. Cohn has succeeded in demonstrating the characteristic reaction of vegetable cellulose (blue colouring by iodine and sulphuric acid) in the envelope-cell of *stephanosphaera* (one of the volvocineæ).

Cohn further states that all analogy of structure and development, as well as natural relationship, indicate that the volvocineæ are to be placed as a special family under the tribe Palmelleæ, of the order Algæ. They are allied to the green-snow plant (*chlamydococcus*), a unicellular alga. The distinction between them consists in this, that in *chlamydococcus* the individuals produced by the division of the green globules separate after the absorption of the parent envelope, and continue to live as distinct individuals; while in volvox, the new cells produced by the division of one green primary cell remain connected by the persistent parent cell as a common envelope, and move about as a well defined body composed of many cells.

CIRCULATION OF THE SAP IN PLANTS.

The circulation of the sap in plants has long been a subject of dispute among physiologists, and there is still much obscurity connected with it. HOFFMANN has recently examined the subject. His experiments were conducted by making plants absorb a weak solution of ferrocyanide of potassium, and afterwards a solution of chloride of iron, by means of which a blue colour was produced in the tissues in which the two substances met. He found different results according as the roots were entire when the absorption took place, or were cut across. In the former case, the fluid entered certain cells and vessels and was excluded from others, while in the latter it entered all indiscriminately. In the lower classes of cellular plants, fluids were found to pass through all the cells of the plants, and no particular course could be detected. In Ferns the fluid did not penetrate the scalariform and closed spiral vessels, which were ascertained to contain air. In Monocotyledons the unrollable spiral vessels, and the annular vessels, were found to be air-carrying and not to contain sap. In the case of Dicotyledons, the spring sap, before the leaves are developed, seems to pass through the spiral vessels and the bark. In summer there is a rapid ascent of crude sap, a descent of unelaborated fluids after every fall of rain by leaf absorption, and a descent of elaborated fluids from the leaves to all parts of the plant. When the summer sap flows in moderate quantity, it ascends in the cellular tissue, the newest woody tubes, and the delicate elongated cells surrounding the vascular bundles; but when the absorption of fluid is rapid and large, the sap passes all into the spiral vessels, which are made to part with a portion of their air. When fluid is absorbed by the leaves, there is a rapid descent of unelaborated sap, which passes into the spiral vessels as well as the cells surrounding them. These experiments of Hoffmann confirm the opinion of Bischoff and others, as to the aerial contents of spiral vessels, and show that they only contain sap in certain circumstances, such as the rapid entrance of much fluid, or accumulation of sap in spring before the transpiration by the leaves has commenced.

MOHL gives the following views of the circulation in plants. Watery fluids are absorbed by the cells of the root, and after passing into the wood, ascend through the stem and branches. As proofs of this, he states, that if a ring is cut out of the bark of a tree, down to the wood, there is no interruption of the passage of sap upwards to the parts above the wound; but if the wood is cut through while the bark is uninjured, the passage is

the plant above the wound speedily dries up. After passing through the stem and branches the sap reaches the leaves, and in passing through their cells it parts with much watery fluid, is elaborated by the action of air and light, and is thus fitted for the purposes of nutrition. Its after course is from the leaves to the bark, and then to the lower parts of the plant. If a ring of bark is cut from a stem, the growth of the part below the wound is, as it were, arrested, the stem does not become thicker, and, in the case of the potatoe plant, there is no production of tubers; on the other hand, the growth above the wound is unusually augmented, very thick layers of wood are deposited, the fruit is produced in larger quantity and is ripened sooner.

FORMATION OF THE CELL-MEMBRANE.

The formation of the cell-membrane has usually been referred to a kind of protoplasm, or azotized matter, which is deposited in a regular manner round the cavity of the cell. AGARDH, however, has recently maintained that, in place of a homogeneous membrane, there is found in the cell-walls a multiplicity of fibrillæ, which by their union and crossing form the cell-wall. He has traced this especially in *conferva*, *melagonum*, *Griffithsia equisetifolia*, and *polysiphonia complanata*. In some sea-weeds, as *Codium Bursa*, he finds numerous loose fibres, which seem to form the tissue. In place of referring the origin of spiral fibres to the mode in which the thickening matter is deposited, he considers the fibres or fibrillæ as elementary organs. These views seem to coincide with those promulgated by Dr. Martin Barry, and which have been recently adopted by Dr. Cobbold from an examination of the contractile tissue of actinia, in which he has demonstrated distinct spiral fibres.

SOURCE OF NITROGEN IN PLANTS.

The source of nitrogen in plants has been chiefly referred to ammonia, which is present in the form of carbonate in the air, and is given off by decaying animal and vegetable matters. That nitric acid contributes to the supply of nitrogen has also been conjectured. The source of this nitric acid is stated to be thunderstorms, which cause a union between the oxygen and the nitrogen, or perhaps the ammonia of the air. M. BANAL, a French chemist, has recently shown that nitric acid is much more abundant than Liebig and others have supposed. He examined carefully the water collected in the rain gauges of the Paris Observatory, and his mode of investigation has been approved by Dumas, Boussingault, and Arago. He states that the following are the monthly average quantities of the substances found in these waters:—

Nitrogen . . .	129 grains in a cubic metre.
Nitric acid . . .	294 "
Ammonia . . .	55.7 "
Chlorine . . .	35 "
Lime . . .	100 "
Magnesia . . .	32.7 "

These experiments show that the quantity of nitric acid is very large, and that rain water thus supplies a valuable source whence plants can procure nitrogen.

ANATOMY AND PHYSIOLOGY.

ON THE FUNCTIONS OF THE MEMBRANA TYMPANI, AND ITS MUSCLES, IN THE HUMAN EAR.

MR. TOYNBEE, in a paper recently published in the *British and Foreign Medico-Chirurgical Review*, Jan. 1853, has endeavoured to determine the exact functions performed by the two muscles of the tympanum, viz., the *tensor tympani* and the *stapedius*.

With regard to the *tensor tympani*, anatomists are pretty well agreed that its action is to draw tense the membrana tympani, and, at the same time, to compress slightly the fluid in the labyrinth. The functions, therefore, of this muscle, appear to be: 1, to prevent the membrana tympani being thrown into such extensive movements by loud sounds, as would injure its functions, or even produce a rupture of its laminae; 2, to prevent it being injured or ruptured by a concussion of the air in the external meatus, through a blow on the ear; 3, by drawing the membrana tympani tense, to enable it to withstand the pressure against its outer surface of foreign bodies accidentally pushed into the ear, and against its inner surface of air forcibly introduced, as during the act of blowing the nose; 4, by slightly compressing the fluid in the vestibule, when it presses the base of the stapes gently inwards, it prevents the expansion of the auditory nerve from being injured. In its functions, the tensor

tympani muscle thus appears to be analogous to the circular fibres of the iris.

The *stapedius muscle* has generally been looked upon as an aid to the tensor tympani. Careful examination appears to leave no doubt that the two muscles are antagonists, and that, while the tensor tympani has the function of drawing tense the membrana tympani, and of compressing the labyrinthine fluid, the stapedius muscle relaxes the membrana tympani, as well as the fluid of the labyrinth. This opinion was advocated by Treviranus and by Huschke, in 1845; and Mr. Toynbee has experimentally shown its correctness. The following observations are condensed from Mr. Toynbee's paper:—The circumference of the base of the stapes has been considered by anatomists as being connected to the margin of the fenestra ovalis, by means of a ligament. If the circumference of the base of the stapes be carefully examined by means of a lens magnifying three or four diameters, it will be apparent that it presents a free surface, bounded by well-defined margins. This is called the *circumferential surface* of the base of the stapes, which, in the recent state, is covered by a very delicate layer of cartilage; and this surface articulates with the inner part of the fenestra ovalis. To the margins of the articular surface of the fenestra ovalis, the margin of the articular surface of the base of the stapes are connected by two distinct circular ligaments, between which there exists an articular cavity, and in this cavity the base of the stapes moves to and fro like to a piston in a cylinder. In order to ascertain in what way the stapes is influenced by the action of the stapedius muscle, the following experiment was performed. By means of a small pair of cutting forceps, a section was made through the cochlea, a portion of which was allowed to remain connected with the vestibule. The scala vestibuli of this portion will be observed to be filled with fluid as far as the margin of the section, which fluid is of course continuous with the perilymph in the cavity of the vestibule. If the stapedius muscle be now pulled, or if the neck of the stapes be moved slightly backwards, the fluid in the exposed part of the scala vestibuli will be found to recede slightly into the scala vestibuli, and its surface to become concave; as soon as the stapes is allowed to return to its quiescent state, the fluid again passes into and fills the scala vestibuli, and assumes a rounded surface. Independently of this action on the contents of the vestibule, the stapedius muscle produces a slight degree of relaxation of the membrana tympani. It would therefore appear that the stapedius muscle is the direct antagonist of the tensor tympani, and that it is called into action in the process of listening; it would appear to act as the analogue of the radiate fibres of the iris.

The above observations indicate that one function at least of the membrana tympani, the muscles and ossicles of the tympanum, is to act as the analogue of the iris in the eye, and to regulate the amount of sonorous undulations that are to pass to the labyrinth.

ON PHOSPHENE, OR THE LUMINOUS SPECTRUM PRODUCED BY PRESSURE ON THE EYEBALL.

Several articles have appeared in the French medical journals during the last two or three years, on the subject of phosphene,* and the *Gazette Médicale* for January 15th contains a summary of some observations made by M. SERRE, of Alais, at a meeting of the Academy of Medicine.

Abrupt pressure on the eyeball, behind the line of juncture of the cornea and sclerotic, causes, at the *opposite point* in the interior of the organ, a sensation of a luminous ring. It varies in colour: it is generally whitish—sometimes blueish. The included space may be quite dark, or slightly clear: in the latter case, it contains a second ring, concentric with the first, and of a deep tint. This annular luminous appearance constitutes *phosphene*.

The ring is sometimes quite circular, sometimes elliptical, sometimes interrupted at one or more points. According to M. Serre, the ring is never entire; it always presents a lacuna, which is invariably directed backwards, and is less in the image on the temporal side than in others, especially in the supra-orbital image. This indentation has not been noticed by Müller or by Brewster, who have directed particular attention to phosphene. Dr. Dechambre, who writes the notice of M. Serre's communication in the *Gazette Médicale*, doubts whether the interruption is of so constant occurrence as is described by M. Serre. He has several times succeeded, by pressure on the inner side of the eye, in producing an unequal circle, broken at a number of points, but *without a lacuna*. A slight degree of

* From *phos*, light, and *phew*, I cause to appear.

pressure gave rise to the appearance of a segment of a ring; and probably the interruption in the circle would be due to insufficient pressure.

The phenomenon lasts only one or two seconds, if the pressure be rapidly made, so that the eye receives a sort of shock. If the pressure be continued, the image is gradually effaced, in a variable space of time. Its intensity is greatest when the eye is in the greatest amount of darkness. The experiment succeeds best just after transition from a very light to a dark medium.

At the same time with the image on the opposite side, there is often perceived, at the seat of the pressure, a second image like the first, but smaller and less luminous, and requiring great attention to perceive it. The indentation appears turned in the same direction as that of the other image. The double spectrum is produced whether the eyes be closed or open.

Several explanations of this phenomenon have been offered. Sir D. Brewster explains it by supposing that the retina undergoes pressure at two points—one at the part directly pressed on, and the other in an opposite direction. A ring of liquid is formed round each of these points. If pressure on the cornea does not produce phosphene, it is because it ends in the *punctum cæcum*. This explanation, which is accepted by M. Serre, is at present that which is most satisfactory.

M. Serre has endeavoured to apply this phenomenon to the physiology and pathology of vision. What is the meaning of the phenomenon? It means, first, that a mechanical impression on the retina gives rise to a sensation analogous to that produced by its proper stimulus, light; secondly, that the impression made is transmitted to the opposite point of the retina, in virtue of a physiological law, and without the intervention of known physical laws. M. Serre states that the crystalline lens is traversed at its centre, by the line passing from the point of contact to that where the object is perceived. If this be true also for images formed by the action of light, the inversion of the image produced by the crossing of the rays, becomes corrected without the intervention of any operation of the mind. This theory is, however, founded on uncertain data, and scarcely agrees with the explanation of phosphene given by Sir D. Brewster, and adopted by M. Serre.

M. Serre has applied the phenomenon of phosphene to the diagnosis of some diseases of the eye, especially paralysis of the retina. The phenomenon is not always produced at will, nor at the first trial; but it is impossible to find it absent during several days, without concluding that the retina has lost its power.

EPIDEMIOLOGY, HYGIENICS, AND STATISTICS.

THE FURUNCULOID EPIDEMIC.

THE year 1852 has been distinguished by two epidemic visitations, one of them appalling in severity, the other less destructive, but extraordinary, if not unique, in several respects. We allude to the *small-pox*, and to the (so called) *furunculoid epidemic*. On the present occasion we shall speak of the latter disease, tracing its chronology up to the end of 1852; next its territorial extent; and lastly, portraying its pathological character.

CHRONOLOGY. An epidemic of boils, carbuncles, and whitlows, particularly the latter, is described as having occurred as long ago as the year 1834, in the neighbourhood of the Lower Pyrenees, among the soldiers of the 57th regiment of the line. This is noticed by M. Tholozan, in a paper recently read by him at the Société de Biologie, which has just been published in the *Gazette Médicale de Paris* of Jan. 1, 1853.* He relates, that M. Marten, head-surgeon of the Hospital of Colmar, had seen several causes of this epidemic, and collected accounts of many more. Eleven cases of phlegmon of the hands and forearm had come under his own observation, and reports had reached him of one hundred and one similar cases, fifty-three of which occurred in 1834, and forty-eight in 1835. He likewise speaks of the contemporaneous occurrence of many cases of erysipelas, erythema, "eruptions dartreuses", "boutons hémorrhoidaux", abscesses in different regions, particularly in the limbs; boils, carbuncles, some cases of "charbon", and a tendency to phlegmonous gangrene, especially abscesses in the palmar aspect of the hand and fingers, extending along the upper and lower arm. Gangrene, exfoliation of tendons, and caries of bone, are spoken

of as common occurrences. Emollients, narcotics, and general and local blood-letting, were often found powerless in the treatment. Free incisions were practised, and proved frequently useless; the disease being marked by "a principle of malignity which paralysed the effect of treatment". The epidemic disappeared in the winter, and re-appeared in the following March. He attributes the disease (probably without sufficient reason) to high living, the abuse of spices and other stimulants, and to a high atmospheric temperature.

No further notice appears of this epidemic until the spring of 1851, when papers on the subject appeared in the *Medical Gazette* and *Lancet*. We shall endeavour to show, however, that a tendency to carbuncle existed, though in a limited degree, for five or six years previously. The following account is collected from a paper read at the Epidemiological Society, July 7th, 1852, by Mr. Hunt, from a notice by Dr. Kinglake, which has more recently appeared in the periodicals, from a pamphlet by Mr. Ludlow,* and from various private sources. No statistical accounts of this epidemic have yet been published, with the exception of those collected from the Registrar-General's weekly reports by Mr. Hunt. These, however, are confined to the *deaths from carbuncle*, which, having been in this country the only fatal form of the disease, may be taken as an index of its severity and prevalence in the metropolitan districts, to which the registry is restricted. We shall extend this inquiry to the end of 1852. The following table will convey all the information which can be obtained from this source. It shows the rise, progress, and advance of the mortality from carbuncle, up to the present time; and discloses important chronological facts.

DEATHS FROM CARBUNCLE in the Metropolitan Districts, from 1840 to 1852 inclusive. The twelve years may be divided into three periods:—

In 1840, 41, 42, 43, the average was $3\frac{1}{4}$ per annum.

1844, 45, 46, 47,	"	8	"
1848, 49, 50, 51,	"	18	"

Last quarter of 1851, 9 deaths; rate, 36 per annum.

First quarter of 1852, 16 deaths; rate, 64 per annum.

Second quarter of 1852, 5 deaths; rate, 20 per annum.

Third quarter of 1852, 16 deaths; rate, 64 per annum.

Fourth quarter of 1852, 11 deaths; rate, 44 per annum.

Single Years.

In 1846 were registered 3 deaths from carbuncle.

1847	"	15	"	"
1848	"	20	"	"
1849	"	15	"	"
1850	"	19	"	"
1851	"	19	"	"
1852	"	48	"	"

During the seven years previous to 1847, the average number of deaths was only $4\frac{1}{4}$ per annum.

It also appears, that the epidemic of carbuncles commenced in the year 1847, and that, from that time until the summer of 1851, the deaths observed a general average of about four times the amount of the previous annual average of seven consecutive years; and that, during the year 1852, in which 48 deaths occurred, there were nearly three times as many deaths as the annual average of the previous five years, and nearly eleven times as many as the annual average of the seven years ending in 1846. The anthracic mortality during the severe epidemic of 1852, is thus distributed in the different months:—

Deaths.		Deaths.	
In Jan. 1852, were registered	8	In July,	4
February,	5	August,	2
March,	4	September,	10
April,	3	October,	3
May,	0	November,	5
June,	2	December,	2

In the present month (Jan. 1853), during the first two weeks of the month, there were no less than five deaths registered; which shows that the epidemic is still raging with as much malignity as ever.

This monthly table shows that, unlike the above mentioned epidemic in the Lower Pyrenees, in 1834–5, which disappeared in the winter, and re-appeared in the following March, the visitation of 1852 has raged most severely in January and September, disappearing only in May. It appears, in short, to have been entirely unaffected by the temperature of the atmosphere; nor does its course appear to have been influenced either by the re-

* M. Tholozan says, that the earliest notice he has met with of the existence of this epidemic, is in Bayle's *Pratique Moderne de la Chirurgie*, tom. III, article "Panaris"; wherein he states, that in 1760 and in 1767, in the Hospital of London, a great number of cases occurred of whitlow, accompanied with caries, &c. It is impossible, however, to identify these visitations with the present epidemic.

* *On Carbuncular Inflammation of the Lips, and other parts of the Face.* By Harvey Ludlow, Esq., F.R.C.S., late House Surgeon to St. Bartholomew's Hospital. London: 1852. pp. 13. This pamphlet is very interesting.

remarkable drought of the last spring, or the not less remarkable excess of moisture prevailing in the autumn.

TERRITORIAL EXTENT. If the chronology of the furunculoid epidemic is remarkable, its universal prevalence at one and the same time, in different quarters of the globe, is not less so. In England, it has prevailed not only in the metropolis, on both sides of the river, but in every part of the country, both inland and at the coast. Dr. Kinglake, Physician to the Somerset and Taunton Hospital, says he has not only observed it in his own immediate neighbourhood, but has put himself in communication with various medical practitioners in different parts of the neighbourhood (represented by radii of twenty miles and upwards), who have all spoken to the fact of its extraordinary prevalence, in one or other of its forms, in each of their respective localities.* Mr. Hunt reports, that he has seen it on the northern coast of Kent, and heard of it on the southern coast of Hampshire; that he has traced it to every part of the metropolis, to Oxford, Cambridge, Bristol, Manchester, and to several counties of England and Wales. In short, we shall feel obliged by a communication from any of our associates who have not met with it in any part of England, Wales, or Scotland. Tidings have reached us of its prevalence in Ireland and Scotland, in France and Austria. The American journals speak of it as common in New York, Philadelphia, and Washington. In a letter from Dr. Bowerbank, of Spanish Town, Jamaica, dated 28th March, 1852, he says:—"We have had numbers of persons suffering lately from boils, whitloes, and carbuncles. I see the same prevalence noticed in some parts of America." Private accounts have also reached us of its existence in the Cape of Good Hope; and, indeed, it has been present wherever our inquiries have as yet extended.†

PATHOLOGICAL CHARACTER. The epidemic appears to have assumed some shades of difference in various places and at different seasons, as to the precise form and locality of its development; and, among these, the following have been noticed by different observers: viz., 1. *Carbuncles* of every variety, and in almost every region of the body, often showing a remarkable tendency to gangrene; 2. *Furuncles* or *boils*, in every conceivable locality, varying much in size, and often appearing in rapid succession, from one to twenty at a time, for weeks or even months together; 3. *Whitloes*, chiefly superficial, attacking not one finger only, but sometimes several at once; 4. *Felons* (as they are called in America), that is, collections of purulent matter beneath the theca, or tendons of the palmar aspect of the hand or fingers, often terminating in gangrene or caries; 5. *Styes*, or purulent tumours in the tarsi; 6. *Ecthyma*, consisting of a number of small boils or pustules, appearing simultaneously or consecutively, on various parts of the body; 7. Superficial collections of purulent matter beneath the epidermis, in various regions, sometimes commencing in vesications, and tending to ulceration. The carbuncular form of the disease often commences with a black central spot (*charbon*), which is not unlike the true plague-spot; indeed, two of the cases which occurred in St. Bartholomew's Hospital, both fatal, presented, Mr. Ludlow says, "several features of resemblance to the recorded instances of malignant pustule". This may account for the extraordinary mortality attending the disease, and which has prevailed in spite of free incisions, sometimes repeated, and careful constitutional treatment. The fatal cases appear to have occurred chiefly, though not exclusively, in subjects of an advanced age. Thus, in the four deaths which occurred in one day in London, on the 18th of January, 1852, all the persons were about the same age, 68.

Like all other epidemics, the carbuncular has been most fatal among the asthenic and needy portion of society; but the influence of the disease has pervaded all ranks. Mr. Cooper Forster, Surgeon to the Surrey Dispensary, in a paper in the *Lancet*, May 3rd, 1851, describes the epidemic as varying in its development according to the class of society to which the patient belongs; those of the better class having been subject to *acne*, and, having been cured of that complaint, becoming again the subjects of it; while the middle classes are described as visited with true boils in all parts of the body, in some few cases becoming carbuncular: but he has observed the carbuncle to be more common among the poor. The subjects of boils he describes as persons of all habits and constitutions, sickly and healthy, male and female.

CAUSES. The etiology of all epidemics is involved in impen-

trable obscurity. It seems to be the very nature of "pestilence" to "walk in darkness". The prevalence of boils has been attributed to diet, to temperature, to moisture, to drought; but the epidemic has prevailed under all diets, in all countries, at every season, in the temperate and torrid zones, in hot weather and in cold, in extraordinarily dry and in deplorably wet weather; and it is quite certain, that at present we are perfectly ignorant of any existing cause, proximate, remote, or even predisposing, for the existence all over the world, for years together, of a strange tendency to the formation and discharge of purulent matter, chiefly on the surface of the body; for in this consists the development of the disease. It cannot, however, be doubted, that there is some previously depraved condition of the blood, which is thus naturally relieved by elimination.*

With one exception, no writer has yet described the epidemic as in any degree contagious. That exception, however, is important. The *Medical Gazette* for March 7, 1851, contains the report of a lecture delivered by Dr. Laycock in the Medical School of York, on what the distinguished physician terms "a new exanthem", and which he afterwards describes as consisting of boils, which he believes to be the result of a contagious matter, originating in the first instance with brutes, and then transmitted from one individual to another, and not through the medium of the atmosphere. Dr. Laycock, in fact, believes it to be "strictly contagious"; but we are bound in honesty to confess, that we cannot discover in the report of his lecture any evidence of the soundness of this opinion.

To sum up the past history of this remarkable epidemic in few words, we may call attention to the following points:—1. Its tardy and insidious commencement nearly six years ago; its sudden aggravation during the last fifteen months; and its steady and unmitigated prevalence up to the present time, unaffected throughout by meteorological changes, and varying but little in the various latitudes to which it has been traced; 2. Its universal and contemporaneous diffusion over every portion of the globe from which accounts have been received; 3. Its extremely rare fatality, probably not one in fifty thousand of those who are attacked falling victims to its virulence.

THE SMALLPOX AT ZANZIBAR.

The *Semaphore de Marseilles* contains a letter, dated Zanzibar, September 6, 1852, from which the following is an extract. "Smallpox has made frightful ravages both at Zanzibar and in the neighbouring country. Senahillis, Hindoos, blacks—in short, the entire population, with the exception of the Europeans—paid their tribute to the terrible scourge, the germ of which was brought from Muscat by a vessel of the Imaum. In the Persian Gulf and in that of Oman, where cholera had already raged, thousands of victims have succumbed. The disease has spread with frightful rapidity, not only along the eastern coast of Africa, but also in the interior of that continent. The mortality was there so great, that caravans have ceased to circulate, from want of a sufficient number of able-bodied persons to effect the carriage of goods from the interior to the sea-shore. Along the coast, hands are likewise wanting for the conveyance from the sea to Zanzibar. Our market, consequently, suffers from it, and the small quantity of merchandize now in the stores has become the object of the most extravagant competition among the merchants of the place, who cannot without the greatest difficulty, and at immense sacrifices, complete the cargoes of their vessels. The disease is now on the decline at Zanzibar, and hitherto no European resident, or seaman has been attacked by it. It is true we only allow our seamen to communicate with the shore for the wants of the service, and moreover the blessings of vaccination preserve us from contagion. The natives of the country, seeing the happy effects of that preservative which they declined using when it was still time, now crowd to demand the favour of being vaccinated by one of our countrymen, who, though not a physician, is very skilful in performing the operation. In order to encourage them by example, we caused all our servants to be vaccinated, and I need not tell you that they all escaped the effects of the disease."

FEVER EPIDEMIC AT CROYDON.

We learn from the newspapers, that a fatal form of typhus fever is prevailing in the town of Croydon and the adjoining villages. We would be glad to receive an account of it from any member of THE ASSOCIATION in that neighbourhood, who is able and willing to furnish it.

* See an interesting paper on the subject, by Dr. Kinglake, in the *Monthly Journal of Medical Science*, July 1852, p. 18.

† We cannot conceive a more important use which the Epidemiological Society can make of their facilities for foreign correspondence, than to ascertain whether the epidemic has been absent any where.

* Mr. Hunt asserts (*Lancet*, May 24th, 1851), that a similar epidemic, though to a minor extent, prevailed after the cholera of 1832, 3, 4. This appears to be confirmed by the already quoted account of the epidemic, which prevailed in the neighbourhood of the Lower Pyrenees in the years 1834-5.

STATISTICS OF THE FOUNDLING HOSPITAL AT BARCELONA.

In the *Boletín de Medicina, Cirugía, y Farmacia* for December 26, 1852, the following statistics are given of the Foundling Hospital at Barcelona.

The children have very lately been transferred from the general hospital of Santa Cruz to the old house of Misericordia. It appears that, during the last six years, the number of admissions and deaths has been as follows.

Year.	Admitted.	Died.
1847	652	586
1848	578	401
1849	654	511
1850	617	520
1851	607	554
1852	610	475

Total, 3778 3047

This shows a mortality of 83 per cent.

The authorities have taken measures to remedy this lamentable state of things, by removing the children to a more commodious building.

According to M. HERVIEUX, (*Union Médicale*, 1852, Nos. 130 and 140, and *Brit. and For. Med.-Chir. Review*, January, 1853, p. 293), out of four thousand children annually admitted into the Foundling Hospital of Paris, three thousand, or 75 per cent. die. To explain this, impoverishment of the blood, over-crowding, and the insufficiency of nursing, have been referred to: but M. Hervieux ascribes the mortality chiefly to the too prolonged maintenance of the horizontal posture. The infants are, it is calculated, kept lying on the back for twenty-two out of the twenty-four hours. The children die, in fact, of cold and hunger; from the continuance of the horizontal posture, the temperature becomes lowered, the limbs chilled, the circulation languid, and the respiration embarrassed: the skin becomes indurated, and visceral congestions take place.

Another cause of disease and mortality to be taken into account, is the feeding. Four, six, or eight times a day, can scarcely be considered sufficient. At present, the eighty-four infants at the *crèche* have only nine nurses and two night nurses to attend to them; while M. Hervieux considers that one woman cannot pay suitable attention to more than two infants.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the meeting of the Committee, on Tuesday, the 25th ult., after the customary business had been gone through, and the various acknowledgments of grants had been read, the Treasurer made his usual report of the state of the finances, by which it appeared that the Fund was largely in debt to the Treasurer for advances.

The Treasurer also reported, that he was in communication with a benevolent gentleman from the West of England, who was about to erect six small houses, which he proposed placing at the disposal of the Committee, for the reception of some of their annuitants. It was resolved, that such offer be gratefully accepted.

The following cases were then presented:—

I. A medical man, with wife and five children, accustomed to a seafaring life, and destitute of employment. To assist him in obtaining such employment, and the means of obtaining a livelihood, £10 were directed to be placed in the hands of Mr. Toynbee, the Honorary Secretary to the London Committee.

II. A gentleman, æt. 74, possessed of the highest testimonials, who had lived the laborious life of a faithful assistant, but who now, as years had increased upon him, as well as the infirmities of age, was incapacitated for active duty, and found himself, at an advanced age, without the means of support. It was resolved to make a grant of £15 to him, in two half-yearly portions; and to place him upon the list of candidates for an annuity.

III. This case was miserably poor, disabled from obtaining employment by paralysis agitans. He had been previously relieved, and was now voted only £5, in the hope that he might yet find employment as a writer.

Cases IV, V, VI, VII, VIII, were referred for further inquiry, or as being incomplete from one cause or other.

NOTICE TO MEMBERS:—PAYMENT OF SUBSCRIPTIONS.

MEMBERS who have not yet paid their Subscriptions, are requested to forward the amount due, either to the Treasurer (Sir CHARLES HASTINGS), or to the Secretary of the Association, at Worcester.

Gentlemen, joining the Association, are required to observe the 24th rule, which states, that "each member is to pay one guinea annually; and that the subscription commences on the 1st of January in each year, and must be paid in advance."

JAMES P. SHEPPARD, Secretary.

NOTICES BY THE EDITOR.

A LIST OF THE MEMBERS of the Association is preparing for publication. It will include all the new members up to date. Gentlemen who have new members to propose, ought, therefore, to do so without delay.

MEMBERS and others are requested to send books, manuscripts, and letters for the EDITOR, to his residence, Essex House, Putney, London; or to the office of the Journal, 37, Great Queen Street, Lincoln's Inn Fields, London.

Dr. CORMACK will attend at the office, to receive members, every WEDNESDAY, from four to a quarter past five, p.m., when not unavoidably prevented by other duties.

To prevent delays or mistake it is particularly requested that all advertisements and letters connected with the alteration of addresses, or with the commercial department, be addressed to the publisher, Mr. THOMAS JOHN HONEYMAN, and not to the Editor.

EDITOR'S LETTER BOX.

CLAIMS OF THE UNIVERSITY OF LONDON TO ELECT REPRESENTATIVES IN PARLIAMENT FOR THE MEDICAL PROFESSION.

SIR,—In your last number, there is a letter from Dr. SNOW BZCK, Secretary to the Franchise Committee of the University of London, in which he states, that "they will be much gratified to know they have the influential support of the medical profession in the provinces, as well as in London, in their endeavours to obtain representatives in Parliament for the University of London". In the same letter, there is quoted a resolution of the Lecturers of the York School of Medicine, an affiliated school, who think the scheme "highly desirable, inasmuch as the medical profession might thereby obtain a more direct voice in public affairs"; and are only solicitous to know whether the franchise should not be conferred on them, the said teachers, respectively of their being graduates of the University.

This leads me to observe, that the just desire which has so long been felt by the medical profession, to have a certain number of representatives of their own in Parliament, to advocate their interests, and stand up for their just rights, has lately appeared to me in some measure to have given place to an agitation which is being actively carried on (it is said, not without some prospects of success) to obtain a representative for the University of London. Now, I have no objections that the University of London, and every other university in the kingdom that has now no representatives, and possesses a respectable and sufficiently numerous body of graduates, should have the privilege of sending one or more representatives to Parliament. Such a set of enlightened and educated constituencies would surely be better than many of those with which Committees of the House of Commons have lately had to deal, and of which many yet remain to be dealt with, before the scandals of our representative system can be abated. In the new Reform Bill which is said to be impending, such a distribution of political power would be to place it in safer hands, though of course less palatable to the masses, before whom everything must now give way, than to lower the franchise, or give more members to large and already too powerful constituencies; but that the graduates of the University of London are to be allowed, or are competent, to choose one or more members of Parliament, to represent the interests and command the confidence of the great body of the profession in this country (including the many physicians in London and the provinces who are graduates of other universities), is a pretension that cannot for one moment be listened to. Of the physicians practising in England and Wales, not one in twenty is a graduate of the University of London; and yet these last are to choose persons to represent not only their fellow-graduates of

other universities, but the large and respectable body of general practitioners who possess no medical degree from any university! Nor is there the least security that the member to be given to the university will be the sort of person on whom even the fraction of medical men who contribute to form his constituents, will be able to rely, as being practically acquainted with, and thoroughly devoted to, the interests of the profession; for the University of London is made up of an aggregation of affiliated schools and colleges in London and throughout the country, a considerable proportion of which are not medical, but theological seminaries, and (the members of the church having their own academical institutions at Oxford and Cambridge) theological seminaries of a peculiar cast, for the training of ministers of the various dissenting denominations. It has, hence, other graduates besides medical ones to swell the numbers of its constituent body. It grants the degrees of M.A., LL.D., and similar literary and philosophical distinctions, for which the alumni of these dissenting theological colleges, and others not studying for the medical profession, become candidates.

It appears, then, that the member who is supposed to give the medical profession a more direct voice in public affairs, is to be elected, not by a small section of that profession even, but by a mixed constituency, one portion of which will certainly take very little interest in medical questions, but a great and active one in questions of a peculiar political and religious hue. Can any reasonable person doubt which class of questions is likely to have the most weight in determining the choice of a representative?

There is only one university in the United Kingdom, that of Edinburgh, in which its medical graduates would have a preponderating voice in the election of a Member of Parliament, were one to be conceded to them; and, inasmuch as they are engaged in practice, in great numbers, in their native places and elsewhere throughout the country, they would certainly have a better title to act on behalf of the medical profession, than the comparatively small number of graduates of the University of London. Still, they are not the profession; and, although the number of those taking their degree of M.A. at that university, preparatory to entering upon other pursuits in life, is now extremely insignificant, a degree not being required for entrance upon such pursuits; yet it might be expected speedily to increase, so as to affect the purely medical character of the constituency, were the privilege of a vote attached to it.

I freely acknowledge that the question, how a hearing is to be obtained for the claims and interests of the profession in Parliament, is one of extreme difficulty, and which can scarcely be entertained by our public men without raising up a host of similar demands on behalf of other professions and great public interests—demands which, it might not be difficult to show, have a less solid ground to rest upon, but which would not the less embarrass and complicate the subject. But let not the medical profession imagine that this question can be settled to their satisfaction by a measure so partial as enfranchising one learned constituency (and that the youngest of those who yet remain unenfranchised), and forming a mixed electoral body, in which there is no security, and, in point of fact, no right to expect that the medical element shall predominate.

G. PATERSON, M.D.

Tiverton, 31 January, 1853.

P.S.—I trust that I shall not be misunderstood as intending to cast a reflection upon the University of London, on account of its being open to persons of all religious persuasions, any more than I would be supposed to cast blame upon its founders for not making it exclusively a medical school. But I ask, if the University of London be not exclusively a medical school, and if its non-medical graduates, or at least an active and influential portion of them, will have views and interests of their own at heart, for which they will naturally seek an exponent in the person of their representative, what becomes of that influence in public affairs which the medical profession is taught to expect from the enfranchisement of that particular University?

NEWS AND TOPICS OF THE DAY.

ALLEGED HOMŒOPATHIC CURE OF THE OCULAR DISEASE OF MARSHAL RADETSKY.

The great temporary impulse which was recently given to the homœopathic imposture in Vienna, by the case of the celebrated Marshal RADETSKY, was the subject of conversation in the

medical circles of London, during the visit of Professor JAEGER, of Vienna, at the time of the Great Exhibition. An authentic narrative of the facts of the case will, however, we dare say, be still acceptable to our readers.

The *Monthly Journal* for the present month, contains, Professor Jaeger's explanation of the case.

In January, 1841, Dr. Hartung, physician to the Austrian army, and to Count Radetzky, wrote from Milan to Professor Jaeger, for advice respecting a disease of the eye, with which the marshal was affected. The patient was seventy years of age, and reckoned fifty-six years of military service. He was vigorous and robust, but subject to catarrhal and rheumatic affections, which became more frequent and intense with the approach of old age. The history of the attack of disease of the eye is thus given by Dr. Hartung:—

"The marshal, on the 9th of October, 1840, during the manoeuvres of the camp at Pardenone, exposed himself for six hours consecutively, and on horseback, to the overpowering heat of the valleys, and the currents of air on the heights. He was suddenly seized, in consequence, with violent fever, accompanied by severe pain in the forehead and temples: there arose, at the same time, an inflammation of the right eye, and of the soft parts around it; and the globe of the eye was pushed considerably from the orbit. The pain was so severe that the patient could scarcely endure it, and was obliged to go to bed. During the night, the intensity of the affection diminished, so that his excellency was able next day to attend a military parade, and some days after to return to Milan.

"The inflammation of the eye, as well as the fever and pain, soon disappeared; but, in addition to the old infirmities, there remained a greater degree of redness of the eyelids and swelling of the conjunctiva than formerly, and a tumour was now perceptible to sight and touch in the external angle of the eye, which caused the globe to protrude from the orbit.

"This aggravation, however, did not prevent his excellency from retaining the command-in-chief, nor from occupying himself, as before, with the affairs of the service.

"The treatment was, from the commencement of this attack, as it had been previously, strictly homœopathic, the remedies having been administered in the following order:—

"1. Aconit. 2. Baryt. carbon. 3. Zincum metall. 4. Anacardium orient. 5. Calc. carbon. 6. Euphrasia. 7. Mercurius Hahnemannii. 8. Merc. sublim. corros. 9. Antimon. crud. 10. Digitalis."

As these remedies failed to produce benefit, Dr. Hartung diagnosed the growth of a fungus in the orbit; and Professor Flarer, of Pavia, diagnosed a scirrhus tumour.

Dr. Jaeger was, at the time when he received Dr. Hartung's communication, with one from Dr. Flarer, ordered to proceed to Milan, to consult and report on the case of Marshal Radetzky. After examining the patient, the consultants were informed by him that "he would be treated by no other physician than Dr. Hartung, and in no other way than according to the homœopathic system." Drs. Hartung and Flarer still adhered to their opinions as to the nature of the disease; while Dr. Jaeger regarded it as the product of a rheumatic periobitis, which, having taken an unfavourable turn, must have degenerated into a scirrhus disease. Yet he believed that, if an increase of inflammatory action took place, a cure might supervene after an evacuation of pus. As this view, however, did not meet the assent of Dr. Hartung, the basis of the report to Vienna was the original diagnosis,—the presence of a scirrhus degeneration of the soft parts within the orbit, threatening to pass into the state of cancer.

Some weeks after having returned to Vienna, Dr. Jaeger heard, by a letter from a relative of Count Radetzky, that the pain had increased, and that there was a copious discharge of pus; and this was confirmed by a report addressed to the minister of war.

While this change was going on, Dr. Hartung, after effectually throwing impediments in the way of Professor Flarer, who was again called to the patient, wrote to Dr. Jaeger "that the marshal, having continued to be treated according to the principles of homœopathy, had got well; that the fungous tumour of the orbit had disappeared; that the pain had ceased: that the eye had recovered its mobility, and that the change of fungus into carcinoma was no more to be dreaded; and he regretted that Dr. Flarer had not had an opportunity of convincing himself with his own eyes of the favourable change!"

After some controversy had taken place on the subject, nothing more was said till 1849, when the victories of the marshal aroused in the homœopaths the idea of trying to gain thereby a new triumph for themselves; and the case has hence been paraded,

with false premises and conclusions, and injurious imputations with regard to Dr. Jaeger.

Dr. Jaeger concludes by reiterating his conviction, that the disease was from the beginning nothing more than simple rheumatic periorbitis, which had gone on to suppuration. The diagnosis was difficult; and on this, of course aided by no small amount of assurance, the homœopaths have blazoned forth the cure of malignant disease of the eye in Marshal Radetzky, as a splendid triumph of homœopathy. Dr. Jaeger completely demolishes their pretensions.

THE LATE DR. PEREIRA. A Sermon, in commemoration of the decease of this lamented Physician, will be preached in the Chapel of the London Hospital, on Sunday Morning next, at Eleven o'Clock precisely, by the Rev. E. J. Nixon, Chaplain of the Hospital.

HOMŒOPATHY IN EDINBURGH. "I would willingly have been spared the occasion of referring, even for a moment, to other losses than those we have sustained by the hand of death. Our own act—justified by a stern necessity, and imposed upon us by a due regard to the interests of science, and the honour of our profession—has severed from us some who were our late associates in the business of the Society, all of whom we would have gladly retained, and none of whom we can afford to lose: but they were not of us. They had abjured the faith in which they were educated, and in virtue of which they had obtained status, and honour, and emolument; they vilified the doctrines which they once taught, the teachers whom they delighted to honour, and the brethren with whom they took counsel together; they absented themselves from the colleges, and societies, and convivial meetings in which they once took delight; they waged war against their quondam friends, and against their former selves; and all this without a vindication, or, at best, with but a feeble and abortive attempt to palliate their conduct. The patience and forbearance which we long manifested, were exhausted and overcome; and, by an almost unanimous voice, we declared them no longer members of the Medico-Chirurgical Society. We commiserate their position: we lament the injury done through them to a noble profession; but we rejoice in the hope that the age which has seen the rise of this fatal apostasy, may, long ere its close, witness its decline and downfall, when, after years of penitence, our alienated brethren may be received again into the fellowship and the privileges which they have so recklessly sacrificed."—(From Dr. BEOBIE'S Valedictory Address, on resigning the chair of the Medico-Chirurgical Society of Edinburgh, Dec. 8th, 1852.)

THE INCOME TAX ELUCIDATED.—The In-come Tax is a funny Thing. It is a Tax up-on a Man's In-come. A Man's In-come is all the Mo-ney he gets in one Year. Many a Man has no-thing else in the World than the Mo-ney he gets in one Year. He pays In-come Tax on all that Mo-ney. He pays Se-ven Pence out of ev-e-ry Pound of it. Mo-ney is pro-per-ty. If a man has No-thing else than the Mo-ney he gets in one Year, that Mo-ney is all his Pro-per-ty. So if he pays In-come Tax up-on it, he pays a Tax on all the Pro-per-ty he has got. But ma-ny Men have a great deal more Pro-per-ty than the Mo-ney they get in one Year. Some have Twen-ty Times as much Pro-per-ty as that. Yet they only pay a Tax on the Mo-ney they get in one Year. They pay no more than Se-ven Pence out of ev-e-ry Pound of that Mo-ney. They do not pay a Far-thing out of all their o-ther Pounds. So, the In-come Tax is a Tax on all one Man's Pro-per-ty and on on-ly Part of a-no-ther's. Mr. GLAD-STONE says this is just. If Mr. GLAD-STONE had no-thing but what he could earn, he would not be so well off as he is now. And yet he might have to pay Se-ven Pence out of ev-e-ry Pound he was worth. Mr. GLAD-STONE would not be glad then. He would be Sor-ry. I do not think he would call the In-come Tax just a-ny longer; do you?—*Punch*.

APPOINTMENTS.

[*An asterisk is prefixed to the names of members of the Association.]

BLAKE, V. W., Esq., was elected, on the 5th of January, to be one of the Medical Officers of the Birmingham and Midland Counties Lying-in Hospital, in room of Dr. Elkington, resigned.

BROOKE, Charles, Esq., F.R.C.S., elected Assistant Surgeon to the Westminster Hospital.

FINCHAM, G. F., M.D., elected Assistant-Physician to the Westminster Hospital.

***KIRKMAN, William P., Esq.,** appointed Assistant-Surgeon to the Suffolk County Lunatic Asylum.

MILLER, James, M.D., elected Physician to the St. Marylebone General Dispensary, in the room of Dr. Wadham.

ORFORD, W. C., Esq., was elected, on the 5th of January, to be one of the Medical Officers of the Birmingham and Midland Counties Lying-in Hospital, in room of Dr. Mackay, resigned.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were members of the Association.]

GREEN, Joseph Septimus, Esq., Surgeon at Newcastle-upon-Tyne, on Saturday, January 15, aged fifty-four.

GREGORY, George, M.D., at his residence, 6, Camden Square, London, on the 25th January, from disease of the heart and consequent dropsy. Dr. Gregory was a man of integrity, talent, and learning; but his popularity as a practising physician was impaired by his abrupt and unpremeditated remarks when called in consultation. His principal works are: 1. *Elements of Medicine*, which went through six editions; 2. *Lectures on Eruptive Fevers*; and 3. The article, *Small-Pox*, in the *Cyclopædia of Practical Medicine*. He was, likewise, the author of various papers on different subjects, but particularly on Small Pox and Vaccination, in the Medical Journals. His scepticism as to the advantage and propriety of vaccination recently attracted considerable attention, but did not diminish the confidence of the public or of the profession in the value of the discovery of the immortal Jenner. Dr. Gregory held the office of Physician to the Small-pox Hospital, and Lecturer on Dermatic Pathology in the School of St. Thomas's Hospital.

BOOKS RECEIVED.

THE ASSOCIATION MEDICAL JOURNAL is published at its own office every Friday evening.

SCALE OF CHARGES FOR ADVERTISEMENTS:—

For seven lines and under	£0 6 0	For a whole column	£3 15 0
For every additional line	0 0 6	For a page	5 5 0
For half-a-column	1 10 0		

Advertisements ought to be delivered at the office on the Wednesday preceding publication.

Post-office orders for subscriptions to the Journal, or for payment of advertisements, are to be made payable to THOMAS JOHN HONEYMAN (the Publisher), 37, Great Queen Street, Lincoln's Inn Fields, London.

N.B.—Members of the Association receive the Journal, free by post, as a matter of right. To others, the terms of subscription are—For one year, unstamped, £1:6:0; ditto, stamped, £1:10:4.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. VI.

LONDON: FRIDAY EVENING, FEBRUARY 11, 1853.

NEW SERIES.

PARLIAMENTARY REPRESENTATION OF THE MEDICAL PROFESSION.

VERY inadequate ideas are commonly entertained regarding the importance of obtaining Parliamentary Representation for the Medical Profession; and it seems unfortunately to be looked upon and written about as *an end* which can only be reached by a toilsome struggle through thorny and devious paths, rather than as *the best means* of carrying out the liberal and just measures of medical reform, which are alike demanded by the interests of the profession and the requirements of the public health. It is also to be regretted that direct representation—the method which it is most difficult to support—is that which has most engaged the attention of pamphleteers and journalists, who continue to expend an amount of energy upon a hopeless cause, which, if diverted to another and an easier means of getting our profession represented in Parliament, might speedily produce fruits.

The past history of parliamentary reform, the present views of our leading statesmen, and the general tone of public opinion, clearly indicate that it is a vain delusion to suppose that the legislature will ever be induced to bestow parliamentary representation upon the medical profession, as a profession; and for this simple but sufficient reason, that, if such a privilege were once conceded to a profession, it might with plausibility be claimed by a host of other special and class interests. If the truth of this view of the case be admitted, the subject at once becomes disencumbered of the many vexatious questions, which its mere mootings has already suggested as likely to arise between rival corporations; and the inevitable conclusion is forced upon us, that, if we are at all to be represented in Parliament, it can only be, for the present at least, in the same way in which other special interests have been in times past, and are now, there represented. Lawyers, West India planters, brewers, and the Pharmaceutical Society, are not recognised in the British constitution as entitled to send members to the House of Commons; yet all of them, by individuals of their respective bodies, have successfully fought their battles in that arena. Is it not folly, then, to be wasting our time and our powers of agitation in a futile attempt to create new and peculiar constituencies, through whom we may hope to make known within the senate our wants and our wishes? Would it not be more rational to adopt a similar course with those to whom we have already referred? Would it not be more easy and more useful to seek out one, two, or three *bond fide* practitioners, good men and true, who will consent to sit in Parliament for such small constituencies as would be willing to return them, and who would not demand from their representatives a slavish attendance on the routine business of the House, or an active participation in every political discussion? This is the only common sense view of the subject; all other schemes for the parliamentary representation of the medical profession are impracticable, and, however abundantly

they may furnish texts for discussion, they will assuredly never yield any practical result.

As regards the attempt now being made to obtain a member for the University of London, we heartily wish it the success which the justice of the cause demands; but we would also desire to see the claims of the elder universities of Scotland treated with equal justice. In none of the non-represented universities do we believe that the medical graduates would be able to command the issue of the poll: and we fully concur with Dr. PATERSON, of Tiverton, in the sentiment expressed in the conclusion of his letter (p. 113 of last number), where he says:—"Let not the medical profession imagine that this question can be settled to their satisfaction, by a measure so partial as enfranchising one learned constituency (and that the youngest of those who yet remain unenfranchised), and forming a *mixed electoral body, in which there is no security, and, in point of fact, no right to expect that the medical element shall predominate.*"

DUBLIN MEDICAL PRESS UPON EXAMINATIONS REAL, NOT VERBAL.

THE *Dublin Medical Press* has reprinted our leading article of the 21st January, entitled, "Examinations Real, not Verbal"; and although "not concurring in all the opinions offered", our contemporary fully admits that "the period has arrived for a free inquiry into the merits and defects of the present system of examination".

The *Medical Press*, however, does us injustice in supposing that we intended to assert that the London University deserves the honour of the "discovery" that *real* should be added to *verbal* examinations; for all we said was, that she has begun prominently to adopt the improvement, and that for this the profession owe her their thanks. We were aware that the Apothecaries' Society—a body constantly but ignorantly and unjustly spoken of by the *Dublin Medical Press*—has for years adopted *real* examinations in *Materia Medica*, in addition to verbal ones, and has not been content with the candidates telling them whence colchicum or cubebs came, and the natural and Linnæan order of the plants, but has likewise required them to know the drugs when they saw them. And we were aware that the microscope has been introduced upon the examination table of the University of Edinburgh, so that there will be less danger of the embryo doctors being unable, when looking down upon it in the instrument, to indicate "the white matter of Schwann", although very accurate as to its exact linear measurement. All that we insisted on was, that this principle should be fully carried out, and that, in addition to the present verbal examinations, the student should be examined in the objects themselves. We trust, for his own sake, that our contemporary of Dublin does not imagine us to be so one-sided and absurd, as to think that anatomy or chemistry, or any other science, can be learned systematically without books, that is, without the assistance of all those who have preceded us, and who have enabled us to master with ease what they discovered with painful toil. All we

assert is—and we are certain that every candid man who knows anything of the matter will agree with us—that by the present system a student may pass an examination in anatomy, in chemistry, materia medica, and the practice of physic and surgery, with very little knowledge of the sciences themselves, and with merely an acquaintance with the words which represent them; and that the prevailing system of examination fosters this mistaken direction of the pupil's industry. We rejoice to learn from our contemporary that the Colleges of Surgeons of Dublin and of London are at this moment engaged in considering this subject; and we trust that the result of their deliberations will be the needed reformation.

We are not of the number of those who love great and sudden changes. We have a strong conservative bias; and can fully sympathise with those who have been actually engaged as examiners for years, who have adopted many improvements themselves, and who daily see where other changes might be effected were it not for circumstances which they cannot singly control. But, on the other hand, like every one who watches the progress of our Anglo-Saxon institutions, we know that all of them require public supervision and public discussion. However annoying it may be to the actual workers to be overlooked and scrutinized, yet suggestions *ab extra* are useful, and often quicken into vigorous life much that might have remained dormant without such a stimulus. Our institutions demand *progress* as well as *stability*: two principles which must work together in our medical corporations, if they are to live and grow, to rise and not to fall. We would repeat then, that what we conceive to be imperatively wanted is, *an addition to the prevailing system*. Let the present plan of systematic examination in words be still carried out, but let there be likewise an examination of the practical knowledge of the candidates in the things themselves. Many of the present staff of examiners, who are highly capable from long experience and ripe acquirements of testing the general requisitions of young men, may neither be willing, nor able to act as demonstrators of anatomy or manipulating chemists. But surely there can be no insuperable difficulty in appointing for this purpose examiners who are engaged in the daily practice of anatomy, of chemistry, materia medica and botany; and who therefore being up to the actual state of their sciences, would examine the candidates on the dead body, and with tests, retorts, drugs, and plants previously to their verbal trials. On the other hand, it is possible that none might be more fit than the present examiners to investigate, at the bedside of the patients, the actual acquaintance of the pupil with manipulations, diagnosis, and treatment.

THE MEDICAL BENEVOLENT COLLEGE.

In our advertising pages of to-day appears the Sixth List of Contributors to the Funds of the Medical Benevolent College. It represents an addition of about £1450:0:0 to the £10,641:15:6 formerly advertised. We hope, and we believe, that the great popularity of this institution will command for it a career of much honour and usefulness. Subscriptions, already flowing with so good a stream into its treasury, are likely to receive a great accession at, and in connexion with, the First Festival, which is appointed to take place on the 4th of May, under the presidency of the Right Honourable the Earl Manvers.

It is gratifying to observe that, in many instances, the same names appear as donors to the "Medical Benevolent College", and to the "Benevolent Fund" of the Provincial Medical and Surgical Association. We trust that a good and generous disposition towards both charities may continue and increase; and that each of us may lay to heart the great truth that, after providing for the wants of ourselves and those immediately dependent upon us, an obligation remains to assist our poor brethren to the extent of our ability,—ever bearing in mind that "it is more blessed to give than to receive".

ADULTERATIONS OF FOODS AND MEDICINES.

THE want of members of our profession, and indeed of almost any class of scientific men in Parliament, is undoubtedly a source of much evil to the community. Party questions absorb almost the whole of the time and energy of the representatives of the people, and subjects connected with the public health can scarcely gain a patient hearing; and when they are reluctantly entertained, the manner in which they are discussed seldom tends to any solid reform, simply because there are few members in either House sufficiently well-informed in the science and practice of hygienics to elucidate such subjects. Were it otherwise, the returns of "Inland Revenue" would no longer disgrace England by exhibiting, as items of income, some hundred thousand pounds as the nation's money profit on those death-dealing compounds called "patent medicines", or on the beastly and demoralizing advertisements by which many of them are obtruded upon society by some of the metropolitan and by almost all of the provincial newspapers. This is an evil to which it will be our duty to make constant reference so long as it remains unredressed.

We are glad, in the mean time, to observe that a correspondent of *The Times*, in Tuesday's paper, forcibly calls attention to the necessity of legislative interference for the purpose of suppressing the nefarious practice so prevalent of adulterating every species of food and condiment. He suggests as a remedy, the appointment of a body of scientific men to assay the food of all classes.

In the following remarks we entirely concur:—

"It seems to me that the powers of such an official body should be large, while the penalties it should be enabled to inflict should be small. The mere publication of the facts in the *Gazette* would be a very severe penalty to the fraudulent tradesman, and a great encouragement to the honest one. The men to fill such offices as these curators of the public food would have, might speedily be found; and what employment could fifteen or twenty of our scientific men be more wisely or profitably engaged on—especially as their services would be occasional—than in protecting their fellow-countrymen from the grievous mischief of adulterated food? And, were the work well done, would the country have the slightest objection to give a just remuneration for their services? I should also suggest that weights and measures might be placed under the control of the same board."

The health of the public certainly requires the appointment of such an official board of assayers; and we would propose that their duty should embrace the testing of medicines as well as of articles of food.

ORIGINAL COMMUNICATIONS.

ON INTESTINAL OBSTRUCTIONS.

By BENJAMIN WEBSTER BROWN, M.R.C.S.Eng.

(Read before a Meeting of the Midland Branch of the Provincial Medical and Surgical Association, at Nottingham, December 2nd, 1852.)*

It is my intention to attempt to point out, first, the causes; secondly, the diagnostic signs; thirdly, the treatment of obstructions of the intestines; and lastly, to illustrate my paper by the history of some of the most interesting cases which have fallen under my own observation.

CAUSES. We are aware that the intestines are endowed with a peculiar property, viz., the peristaltic motion; and it would appear they are assisted in this by a fatty network substance—the omentum,—formed by several duplicatures of the peritoneum, and suspended in front of the alimentary canal.

It seems requisite for the purposes of life, that this peristaltic action should be preserved uninterrupted, to propel the fecal contents onwards; and hence we might at once be led to conclude that some serious derangement to the animal economy would arise from its suspension, whether the cause be mechanical or otherwise.

Experience teaches us there are several causes which have a tendency to retard or suspend the peristaltic action, and entirely obstruct the intestines; amongst these we may class obstinate constipation; ileus; intussusception; stricture of the canal; tumours; hernia, etc.

Before we proceed to obstruction of a more formidable character, we will take its most common cause—constipation of a more or less aggravated kind. This may exist *per se*, and yield to simple treatment; sometimes it is constitutional, and no particular ill consequences ensue primarily; some people, however, suffer considerably from an idiopathic condition, and if remedial means have for a length of time been neglected, a morbid state is very frequently set up in the intestinal tube, and the foundation of more serious mischief is laid, as producing an enlarged colon and rectum; this happens, however, in females more than in males.

But constipation may be symptomatic, as in enteritis, peritonitis, intussusception, stricture of the rectum, or of any other part of the intestines, hernia, etc. It is sometimes the direct cause of some of these maladies, and becomes the harbinger of a more alarming crisis, if not relieved.

Persons who addict themselves to the taking of large quantities of opium, or laudanum, most generally have a constipated state of the bowels, which under peculiar circumstances, or certain stages of disease, may become obstinate, and finally lead to real obstruction. Obstruction in the intestines will frequently be produced by taking into the stomach hard and indigestible substances; as improper food; the swallowing fruit-stones, or other like bodies, which are apt to lodge in the fecal passages, and produce irritation. I have seen a kidney-bean, on a *post mortem* examination, incarcerated in the appendix cæci; in another instance a plum-stone; each of these was the cause of permanent obstruction, and death. Permanent obstruction, accompanied with very acute suffering, occurred in the case of a young lady who had swallowed a large quantity of cherry-stones.

Constipation generally accompanies scirrhus of the pylorus, as well as stricture of the œsophagus, from the small quantity of nourishment which is received into the intestines.

Impacted scybala are a frequent cause of obstruction to the passage of the upper portion in the canal. These will most generally be situated in the rectum; but this unnatural condition of the alvine contents will also take place in other parts of the large intestines, as in the colon, which

has become enlarged sometimes by long neglected constipation, and will lead to alarming results if not dislodged by remedial measures. This is more likely to occur here, from the sacculated structure of this part of the canal.

Spasmodic colic, or constriction of some part of the intestinal canal, is an occasion of obstruction. This may be brought on from constipation, the taking of improper nourishment, or the immoderate eating of acid substances or unripe fruit; drinks too, which are of an acrid character will be a source of it. Instances, indeed, occur in the practice of every medical man, in which, on one or more of these causes, invincible obstruction and inflammation supervene.

Obstruction very frequently arises from intussusception, or the inversion of some part of the intestines; and this may be *progressive* or downwards, or *retrograde* and upwards. A preternatural position of parts is liable to occur in any portion of the canal. From the construction of the parts, the most probable place for such a derangement is at the point where the tube terminates in the cæcum. Instances, however, are on record, in which portions of the colon have descended into itself, and even through the rectum, and *per anum*, so as to represent the appearance of a procidentia.

Intussusception most commonly takes place in the small intestines, in which there may be more than one volvulus. Children who have died from teething and convulsions, have been found on *post mortem* examination, with several volvuli in this portion of the tube, which in some instances, apparently, during life, produced no great inconvenience, and consequently were scarcely suspected. When this has occurred, it has been imagined by M. Louis, that owing to the peristaltic action of the bowels, the parts may again have resumed their normal condition.

Whilst at St. Bartholomew's Hospital, I remember a female subject, apparently about twelve years of age, being brought into the theatre for demonstration before the class. Mr. Abernethy had commenced his lecture on the abdominal viscera, and the small intestines nearly throughout their whole length were found in a state of intussusception, yet none of the usual appearances of inflammation were present. I saw Mr. A. draw out or unfold at least a dozen volvuli; and from the absence of inflammation and adhesions, the intussuscepted parts were drawn out without the least difficulty. What the symptoms or history of the case were during life, it is impossible to say; but Mr. A. at the time delivered some useful remarks.

It has sometimes been questioned how intussusception of the intestines can occur? Mr. Hunter affirmed that the abdominal muscles possessed no influence in forming a volvulus, although a prolapsus ani might be produced by their united agency, as in hard straining, etc. I think, from my own experience, and from the numerous instances on record, that it is probably produced by spasm, the result of cold, or as we have before mentioned, of improper aliments and drinks, or the sudden cessation of diarrhœa of a peculiar character, as well as from sudden emotions of the mind. I have had cases under my own care wherein intussusception has been immediately preceded by a severe attack of diarrhœa, accompanied with considerable twistings across the umbilical region. Others have come under my notice which have been the result of some sudden surprise and alarm, thus giving a shock to the nervous system.

Falling, or jumping from a great height has brought on obstruction in the intestines of an invincible kind; a portion of the ileum has been found to have passed through an opening in the diaphragm into the pleural cavity, and strangulation has ensued. From some such cause, or external violence, or even spasm, a rent has been produced in the mesentery, and a portion of intestine has passed through and become strangulated, and thus obstruction has taken place. A part of the colon has been found in a state of strangulation, having passed through a small opening in the diaphragm several inches into the cavity above.

From a morbid condition of the parts, adhesive bands of organized lymph will frequently be found in the abdomen,

* From the pressure of matter, we have been reluctantly compelled to omit some of the introductory paragraphs of Mr. Brown's paper.

which lead to a permanent obstruction. The intestines have on examination been found glued together in several parts by bands of adhesive lymph; consequently, there has frequently been a contracted condition of the larger portion of the tube. Amongst the French archives, we find an account of a youth of fifteen, who, having neglected a call of nature for several hours, in consequence of not being able to find a place of conveniency, besides being exposed to a cold wind, became ill; he felt a degree of tenesmus, but no effort could procure an evacuation. Warm fomentations were applied over the abdomen, which had become very painful and tumid; enemata were administered, and other means were made use of; yet, although some hardened fæces were brought away, there was no abatement in the severity of the symptoms, which presented every feature of internal strangulation. Death ensued in about ten days from the commencement of the attack. A *post mortem* examination discovered a high degree of peritonitis; the intestines were glued together by the effused lymph, which had formed adhesive bands. The state of the upper portion of the abdomen was found to be a distended condition of the bowels, but the loop of intestine, which was crossed at this point there, was not exist below the ileum. At this point there were bands, and where, consequently, constriction with numbness. The larger portion of the tube was so contracted as to be very unnatural in appearance, and was more like cords; there was also a rent in the mesentery beyond the cæcum, and through this opening a large portion of intestine had passed, and became strangulated.

The next morbid affection to which the alimentary tube is liable, frequently preventing the proper passage of the fæces, and ultimately in most instances terminating in a permanent obstruction, is a scirrhus-contracted state of the rectum. This generally occurs in people, and more frequently in women, who are somewhat advanced in life; it may be confined to a particular part of the bowel, or nearly its whole length may become affected. Sometimes there is more than one constricted portion of the gut, and the diseased part is most frequently found in a gristly condition, accompanied with ulcerated portions of the bowel beyond the constriction. I have found the cæcum near its caput in a scirrhus state, which ultimately produced invincible obstruction, and death under very acute suffering.

This morbid condition of the parts appears to be the result of a slow, chronic kind of inflammation which has been set up, producing, as already observed, a thickening and disorganized state of the bowel, which progresses more or less rapidly: permanent obstruction, which no remedial art can cure, takes place ultimately. A case of this kind will sometimes carry the patient off in a few hours, after intense suffering: or it may be protracted to a much longer period, unaccompanied, apparently, by any severe pain; and the patient will die of starvation.

Occasionally, cases occur where there is obstruction arising from congenital contraction of the intestines. The infant shortly after birth will suffer from vomiting and constipation, which are unrelieved by any of the means usually adopted. A *post mortem* examination reveals the cause of all such suffering; there is an impervious condition of, perhaps, the greater portion of the rectum, or of some other part of the alvine canal.

Then, again, we have hernia under its several and direful forms, cases of which present themselves to the notice of almost every practitioner, whether of a simple kind, or those of a more formidable nature. On these, however, I need not here further enlarge.

Thus I have endeavoured to point out the principal causes which give rise to obstruction in the alimentary tube. There may be a few others, as malignant or other tumours, etc., but it is not necessary that I should dwell longer on these.

DIAGNOSIS. We have already remarked that constipation is frequently constitutional as well as symptomatic. Without waiting to describe the former condition further, it will be well for us to endeavour to point out the *diagnostic* signs which appear to present themselves in the

several causes of intestinal obstruction of a more serious character; which, we have said, may be *mechanical*, or otherwise. And here considerable acumen and experience are requisite. In the former case especially, every practitioner knows the difficulty with which he has to contend, before he can in any way satisfy himself with the precise nature of the affection, or seat of the obstruction; and, after all, he is more generally left in extreme doubt, so true is the remark of Hippocrates, "*judicium difficile*." The general history of a case of this kind, the character of the symptoms, the suddenness of the attack or otherwise, connected with other circumstances, will, in some instances, enable him to draw a just conclusion; but, in other cases, or learning their history, symptoms, and the *post mortem* appearances, and consulting these with his own experience, relieves him but little of his perplexity; so that it appears there is no class of symptoms so characteristic or constant, as will enable him at all times to come to a correct diagnosis.

A scirrhus, or diseased state of the pylorus is usually distinguished by a dense, heavy, yet circumscribed pain in the right hypochondrium. Pain is experienced after each meal, accompanied with a rejection of the food which is taken; constipation, frequently of an obstinate character, invariably accompanies this form of disease. In some cases, where the parietes of the abdomen are thin, the indurated part may be felt.

In a case of intussusceptio, there is mostly considerable difficulty experienced in distinguishing its real character, so varying is it in its attacks. It is, however, generally preceded by an uneasy sensation across the umbilical region, with a dragging down sort of sensation in the intestines, and the pain, which occurs at intervals, in some instances is severe. Sometimes the affection comes on by degrees, and is accompanied with invincible constipation; or it immediately succeeds a severe attack of spasmodic diarrhoea. A gurgling noise is sometimes heard in the abdominal cavity, as if nature made an effort by the peristaltic action to remove the obstruction; and this is marked with a severe increase of pain. Frequently the patient will express himself as having his "bowels fast and tied together." There is, usually, considerable nausea and vomiting of bilious matter; this, however, at first, is not always present; but, as the case becomes aggravated, it is ever an attendant symptom, and it is not unusual to have all the characteristic features of a case of strangulated hernia present; but the absence of any tumour or hardness in the abdominal openings will at once relieve our suspicions on this point, especially when other circumstances are considered. At the onset, the state of the pulse is frequently little affected; sometimes, however, it is full and hard, with pyrexia, and the tongue is generally much coated. Tenesmus prevails without the power of defæcation.

As the symptoms continue, and no evacuations follow, the abdomen becomes considerably enlarged and resonant. The pain, which is fixed and local generally, is little increased on pressure, unless inflammatory action have commenced; during the severe paroxysms, however, if the case last some days, the patient will exhibit an occasional heavy and suppressed moan; frequently the agony is so great, that he will cry out aloud, no relief being obtained by the various postures he may adopt. The respiration, generally, is little affected. As the obstruction remains invincible, the abdomen becomes tympanitic; and, with the vomiting fæcal matter, hiccup occurs. The respiration becomes hurried and short; the pulse sinks, and cold sweats supervene, as the sure preludes of death.

Intussusceptio will be distinguished from peritonitis, enteritis, or hepatitis, by the absence of the usual symptoms of pyrexia in the one, and by the pain and tenderness in the other being much increased on pressure. In peritonitis, the patient can scarcely bear the bedclothes to come in contact with the abdomen; and the position chosen is to lie with the body bent considerably forward, the legs being drawn upwards, in order to relax as much as possible the abdo-

minal muscles. Besides, in these inflammatory affections the respiration is quick and short, and carried on as much as possible by the ribs, so as to ease the diaphragm; considerable pyrexia is always attendant; the pulse beats from 120 to 130 or more in a minute; it is generally feeble, but frequently hard and wiry. In peritonitis or enteritis there is grating of the teeth, as a sign of intense pain of which there is little intermission: whereas, in intussusception, there are intervals of fifteen or twenty minutes between the paroxysms of pain, until the symptoms become more aggravated as the case advances. The skin in pyrexia is usually hot and dry; in intussusception it is cold and moist. These, I believe, are the usual characteristics attendant upon obstruction in the intestines, arising from intussusception: but, of course, as we have remarked, they are more or less variable.

A scirrhus or constricted state of the rectum is usually preceded and accompanied by constipation, and very generally terminates in permanent obstruction of the intestines. It may, sometimes, be known by the pain which is experienced within the anus, or along the sacral and lumbar regions, increased at each evacuation, which, as the disease makes progress, seldom occurs more than once in five or six days. If the constricted portion have existed some time, we may generally form a tolerably correct diagnosis of the case, if we bear in mind other circumstances. The stools are frequently streaked with blood and mucus; and are unnatural in their shape, being more or less flattened.

As the disease advances, tenesmus is frequent, and each scanty stool now is not only streaked with blood and mucus, but discharges of matter likewise take place, when ulcerations have commenced. As there is generally no pyrexia, the pulse is little affected; the tongue is much furred but moist; there is occasionally a hectic flush on the cheeks, the countenance being little disturbed; the patient complains only of occasional pain in the abdomen, which he describes as being of a heavy and forcing character; nausea and vomiting generally, but not always, accompany these cases. The abdomen becomes enlarged and resonant, but without any preternatural heat of the skin. Pressure made by the hand does not increase the pain; enemata are mostly returned on each endeavour to throw them up the bowel. The patient at first will not appear to suffer much in health; but as no evacuations follow the means which have been adopted, an examination *per anum* becomes necessary, and if we judge from the symptoms collectively, little doubt will remain on our minds as to the nature and seat of the occlusion. If the constricted part be situated beyond the reach of the finger, the cautious introduction of moderately sized bougies will aid in forming a right conclusion. Of course, as the constriction increases, and an invincible obstruction to the passage of the fecal contents from above supervenes, the features of the case assume a far different form, and the patient ultimately dies from exhaustion.

I have stated above that organised adhesive bands will frequently occur near the caput cæci and colon. These may have existed for several years without producing much inconvenience; but, continuing to increase in substance by the addition of fresh morbid matter, they induce a constricted state of the part, which has resulted in a permanent obstruction to the passage of the feces; and here all the symptoms of internal strangulation, or spasmodic ileus, may present themselves. The attack will sometimes come on almost suddenly; the pain across the umbilicus, and in the lower part of the abdomen, will appear to be most excruciating; the patient will writhe under it, and put himself in almost every attitude, in the hope of finding some mitigation of his sufferings, and die in a few hours.

Impacted scybala, if seated in the transverse arch of the colon, may be frequently detected through the walls of the abdomen, by pressure with the hand; and, as the symptoms of obstruction become more urgent, there will be considerable enlargement above, in consequence of flatus having collected in the small intestines. When scybala are seated in the rectum, and cause obstruction, they are usually discovered by an examination *per anum*.

Cancerous and other tumours of a malignant character will sometimes form amongst the intestines, and give rise to obstruction. These, if situated in the rectum, are readily discovered by digital examination; and, if higher up, as in the cæcum, or colon, they may occasionally be felt through the abdominal parietes. However, to form our diagnosis aright, we must be guided by the symptoms which have been present throughout, as well as by the history of the case.

When the obstruction is dependent upon incarcerated or strangulated hernia, the symptoms and appearances are so well known to us all, that it is almost impossible we should be at a loss to arrive at a correct diagnosis; so that it would be a waste of time to attempt to describe these. I will therefore pass on to consider the third part of my paper, viz., the treatment demanded in each case.

TREATMENT. It is well known to every practitioner, that there are no symptoms so perplexing as those which result from a constipated condition of the intestines. It would be impossible, however, in the present essay, to do more than give a general outline of the chief causes which lead to this condition, bringing on disease, and so frequently terminating in permanent obstruction. These I have endeavoured to point out as fully as a paper like the present will allow, as well as to describe the symptoms whereby we may arrive at a just diagnosis; but, as those causes and symptoms are constantly varying, much judgment is required in the treatment; for every case of this kind is itself a subject for special study.

Without dwelling on those cases of simple constipation, which almost daily come before us, I will proceed to the treatment of those which are of a more obstinate and too commonly invincible character.

The symptoms may indicate that the passage of the alvine contents is obstructed by a distended bladder, an uterus enlarged from pregnancy, or by other causes which produce pressure upon the rectum. These cases will frequently yield to ordinary treatment; but, if the obstruction be referrible to other causes, such as spasmodic constriction, the lodgment of hard and indigestible substances, the collection of hardened feces in the colon or rectum, intussusception, or the strangulation of some portion of the intestinal tube, stricture of the rectum, or to other mechanical causes of occlusion, the result of our treatment most frequently becomes exceedingly doubtful, and on many occasions it is unavailable. This is shown to be the case, by the mortality which occurs from this class of diseases.

If the obstruction be dependent on scybala which block up the rectum, they should at once be carefully removed *digitis et aliis instrumentis*, and the bowel washed out with an injection of warm water. When the colon becomes enlarged from long and habitual costiveness, and filled with a collection of indurated feces, etc., which prevent the passage of the alvine contents from above, enemata of turpentine, or olive oil, and warm water, or linseed infusion, should be repeatedly injected through a tube carried high up the bowel. The introduction of O'Beirne's tube as far as into the colon, has been proposed, and warm water has been thrown with some force; but, in doing this, some caution is necessary, lest the bowel should be ruptured. Calomel and colocynth, and castor oil in small and repeated doses, should be given. Should the case prove obstinate, and there are severe tormina, attended with nausea and vomiting of bilious matter, hot fomentations should be applied over the abdominal region. An effervescent saline draught may be given to allay the sickness. The administration of an emetic, after the rectum has been emptied, has, in several instances, removed the obstruction, after other means had been tried in vain. If, however, inflammation threaten, the application of leeches to the abdomen, or the use of the lancet, must be resorted to. Very often a case of this kind will continue obstinate for many days, unaccompanied with inflammation.

When the obstruction arises from spasmodic colic, or intussusception in some part of the intestinal tube, our object should be the prevention of inflammation. If symptoms of an inflammatory nature show themselves, and the

pulse be full and hard, accompanied with tenderness of the abdomen, venesection should be adopted, as well as the application of leeches to the part, together with hot fomentations. Where practicable, it is advisable to place the patient in a warm bath of 95° to 100°; emollient clysters are to be administered; and five grains of chloride of mercury, combined with ten grains of the compound extract of colocynth, should be given, and followed by repeated doses of castor oil. If there are violent tormina and spasm, it will be very proper to give a full dose of opium or laudanum; the former in a pill of two grains and a half, combined with three of calomel; the latter in a dose of sixty drops, in any agreeable liquor. This plan will frequently act as a charm. In some cases of obstruction, the persisted use of strong purgatives is absolutely mischievous. If intussusceptio be suspected, half a drachm of tobacco should be infused in half a pint of warm water, and the liquor thrown up as an enema. Emetics have been recommended, and quicksilver has been given in large quantities, with the belief that by its mechanical property the volvulus would be destroyed, and the parts restored to their normal condition; but some judgment is necessary in its administration, lest the mischief be increased instead of relieved. If, however, active purgatives have been administered for several hours, and no evacuations follow, they should be discontinued, and only those of the mildest nature given.

In most cases of obstruction in the intestines, a similar plan of treatment appears to be the one best calculated to relieve the mischief in a medicinal point of view. When the obstruction does not yield to this, chloroform has been recommended; and when symptoms of a severer character supervene, which threaten to extinguish life, it becomes a question how far relief can be obtained by resorting to surgical aid. We are aware, however, there are very few cases of this character which demand operative interference, and those are indeed exceedingly difficult to distinguish.

After a judicious medical treatment has been persevered in for several days, in certain forms of obstruction, without the desired relief being obtained, and symptoms supervene, accompanied with stercoraceous vomiting, etc., are we justified in having recourse to an operation, and exploring the cavity of the peritoneum? We are convinced that the patient will die, if no other means are resorted to than those we have already adopted: shall we cut through the walls of the abdomen, search for the cause of obstruction, and endeavour to remove it? This question is a very important one, and requires much serious consideration. The fact, however, that the abdominal parietes, in consequence of intestinal obstruction resulting from some mechanical occlusion (as well as for the removal of diseased ovaries, etc.), have been cut through, when other means have failed in affording relief, and in several instances with success, might sometimes tempt us to an operation; but, unfortunately, before such a procedure can be justly determined upon, the case has generally been too far advanced. It should be remembered, moreover, that there have been instances of obstruction which have resisted the most judicious medical treatment for two or three weeks together, and the patients have, at length, recovered without an operation. On the other hand, where there was neither vomiting nor inflammation present, they have been carried off within a few hours.

In certain cases of intussusceptio and strangulation, the surgeon, by an operation, might be enabled to relieve the abnormal state in the one, and divide or break down the bands which produce constriction in the other; but, in most cases of internal strangulation, as well as in a scirrhus-contracted condition of the tube, the operation would be wholly inexpedient. It is just to observe, however, that whenever such an operation has been determined upon, it should be undertaken in a warm atmosphere; and the less manipulation is used, the better. Of course, no one would be bold or mad enough to attempt an operation of this kind without a consultation.

It is a question to be decided, whether the place of constriction be situated in the small or large intestines. After

witnessing the several volvuli amongst the small intestines, in the instance where Mr. Abernethy with such ease unfolded the intussuscepted parts, I have sometimes been tempted to inquire, in certain cases of suspected intussusceptio, etc., whether an incision through the *linea alba* might not with safety be made. We know, however, that frequently the invaginated portion, in consequence of an inflammatory process having been set up, becomes firmly adherent; thus proving that, in a case of intestinal obstruction dependent on intussusceptio, internal strangulation, or constriction from adventitious bands, the attempt to overcome the evil by a surgical operation, in the manner we have proposed, can only be looked upon as an extremely hazardous one; and the operator might even be stamped as the murderer of his patient. Indeed, the operation of gastrotomy has been severely condemned by some, amongst whom is M. Hevin, formerly a celebrated surgeon on the continent,* as being exceedingly futile. Encouraged, however, by the marked success which has attended the practice of several others, if I felt convinced that a case of obstruction was dependent on intussusceptio, or strangulation from adventitious bands of recent formation, which threatened to extinguish my patient's life; and if I had ascertained the whole history of the case, besides having apprised the patient and his friends of the grave alternative, and having received the sanction of some skilful and experienced surgeon, I doubt whether I should hesitate to explore the peritoneal cavity by an operation, with the design of restoring the abnormal condition of the tube, and thus removing the cause of obstruction. Judging from the French writings, a celebrated continental surgeon has lately operated with distinguished success in some cases of this character; and it is recorded, that two cases out of three recovered.

The great danger we have to encounter in the operation of cutting through the walls of the abdomen, in certain forms of intestinal obstruction, is the wounding, to a considerable extent, the peritoneum; but is it not warranted in the operation of strangulated hernia? in that of paracentesis abdominis? or in the extirpation of diseased ovaries? In the operation of tying the external iliac artery, we are aware, the peritoneum is carefully pushed aside, and left intact; so, in some cases of intestinal obstructions, it has been proposed to make an opening into the colon from the lumbar region, where the bowel can be reached behind the peritoneum; and here the membrane is preserved. But I much question the propriety of such an operation, if an artificial anus is intended, since, if the patient survives the operation, he really must become an object afterwards loathsome to himself and to those around him.

When the obstruction proceeds from a scirrhus-contracted condition of the rectum, we can seldom do more than adopt palliative means. The forcible introduction of clysters, or of bougies of any kind, cannot be too severely reprobated; by such practice, the bowel is likely to be ruptured, and a false passage effected.

In the treatment of incipient stricture of the rectum, the most simple yet nutritious diet should be adopted, as milk, sago, beef-tea, jellies, etc., and the bowels kept relaxed. The cautious introduction of bougies of various sizes will sometimes be of advantage to the patient, by their gentle dilatation of the constricted part. Various have been the means adopted, or proposed, for the cure, or mitigation of the disease. Desault employed flexible rolls of lint coated with some ointment, and these he gradually enlarged. Morgagni adopted a mercurial plan of treatment. But when there is complete occlusion of the rectum, thus forming a barrier to the further passage of the feces, medical and surgical treatment will generally prove equally unavailing. However, when the abdomen becomes tumid from the obstruction, with intervals of occasional severe pain, etc., hot fomentations may be applied, and enemata of various kinds, as the infusion of linseed with laudanum, etc., should be administered; but, although this plan may serve to lessen

* Recherches Historiques sur la Gastrotomie dans le cas de Volvulus, par M. Hevin.

the sufferings of our patient, he will ultimately die of starvation. The same result will occur when the disease is situated in other portions of the intestinal tube. Malignant tumours, likewise, which tend to cause an obstruction, can only be dealt with by treatment of the mildest character. Tumours of this kind, seated in the lower part of the rectum, with a broad basis, when attempted to be removed by the knife or ligature, usually terminate very unfavourably.

Should the obstruction be dependent on hernia, of course, when it is strangulated or incarcerated, the sooner reduction is effected the better. If alarming symptoms threaten, the measures which we are called upon to adopt must be prompt; the taxis, the warm bath of 95° to 100°, or the injection of a tobacco enema; or what is now preferred, the use of chloroform; each, or all of these should be employed without loss of time. Opium may be given, and venesection sometimes employed; but if these fail to allow us to return the protruded parts into the abdomen, I would, without hesitation, proceed to an operation. The operation for the relief of strangulated hernia has too frequently been considered a cruel and dangerous one. I do not, however, exactly coincide with this opinion, when the operation is *early* performed by one who knows his anatomy well: the many deaths which have followed the operation have been mainly owing to its having been too long delayed, and indeed until fatal symptoms had already commenced. I think I am borne out in this by the sad mortality resulting from cases of this kind, which have been brought into the wards of our great hospitals in London. I have been particularly struck with this: it is owing, as I have said, chiefly to the operation having been too long delayed; the cases have generally been trifled with before the sufferers are brought into the hospital. If I may be allowed to allude to my own experience, I have resolved to operate *early* in the cases which have fallen into my own hands, when other means of reduction had failed; and I am happy to say, with complete success. I am pleased to acknowledge having done so on one occasion in the presence of my friend in the chair, under circumstances too of peculiar difficulty; my patient was seventy-two years of age, and yet lives in the enjoyment of excellent health; there was a large protrusion of omentum and intestine (inguinal hernia), which had become entangled, besides which there were strong adhesions, not of recent formation. Now, if we consult the writings of the Parisian surgeons, we shall generally find that their practice is an *early* operation, and we know with what success.

Intestinal obstruction arising from an imperforate anus, or a partially impervious rectum, must be treated in the manner the case usually demands.

CASE I. I remember the case of a young man, which came under my late father's care, shortly after I had commenced my apprenticeship; but, from the long distance of time, five-and-thirty years, I am unable to do more than give a general outline of the case. The patient, a farming servant, took cold, and in a day or two afterwards complained of severe cutting pains across the umbilical region which extended downwards. Obstinate constipation ensued, and the pains occurred at intervals of every ten or fifteen minutes. Vomiting of bilious matter frequently took place. The usual plan of treatment had been pursued for some days: purgatives had been given—opiates and enemata administered; venesection was had recourse to: and fomentations were applied to the abdomen; yet no evacuations had been procured, even on the seventh day from the commencement. The pain became now more excruciating, and the general symptoms appeared more urgent. The abdomen became very resonant. Quicksilver was next given, but with no improvement. At length, it was decided to have the opinion of Dr. Alexander, then residing at Leicester. The case was concluded to be one of intussusception; and Dr. A. now directed a tablespoonful of quicksilver to be given every half-hour; adding, that this was the only chance left of saving the patient's life. At first, there was no remission of the symptoms; but, after more than seven pounds of mercury had been administered,

the obstruction gave way, and the patient's life was saved, by the bowels being well emptied.

REMARKS. The administration of quicksilver in these cases has been condemned by some. Mr. Hunter thought it might with propriety be given where the intussusception was *retrograde*; and that by the peristaltic action, the parts might become normal. However, he holds out a caution, that portions of the quicksilver may find their way between the containing and inverted bowel into the angle of reflection, and by pushing it further on, increase the disease it is intended to cure. But here we have an instance where the patient's life appears to have been saved by the use of quicksilver alone; but pushed, certainly, to an amount larger than I have found on record.

CASE II. Thomas Cluloe, a labourer, aged 54, was suddenly seized with severe gripings across the umbilicus, which, increasing, caused him to send for me. He appeared to be suffering from some severe obstruction in the intestines. There was continued urgent tenesmus, without evacuations; there were considerable fulness and resonance of the abdomen. The pain was severe at intervals, but not increased on pressure. Pulse 78, and feeble. The man had now been two days without an evacuation. I gave him calomel combined with extract of colocynth, the black draught, castor oil, etc. Enemata were administered; hot fomentations with turpentine were applied to the abdomen. No evacuations followed on the tenth day, and the symptoms becoming more urgent, with vomiting of bilious matter, I gave my patient two pounds of quicksilver in four doses, but without avail. On the fourteenth day, he took a large spoonful of *newly-fermented yeast* every half-hour; and before he had taken a pint, there was a plentiful evacuation. I have seen great benefit result in several cases of intestinal obstruction from the administration of newly-fermented yeast: this has appeared to overcome the obstruction, when other means have proved abortive.

CASE III. Miss K., a remarkably fine-looking young lady, about 23 years of age, had joined an evening party of friends. She appeared to enjoy excellent health, and exhibited all the vivacity natural to her age. After, however, she had retired to her chamber, the inmates of the house were alarmed during the night with hearing her screams. She was writhing with agony. There was intense pain over the umbilical region, which was increased on pressure. Constant nausea, without vomiting, was also attendant, as well as urgent tenesmus. Hot fomentations were applied over the abdomen; calomel combined with opium, and castor-oil were given in repeated doses; and enemata were administered, yet without any evacuations being procured, or remission of the symptoms. Leeches were applied over the abdomen, and venesection was had recourse to. Notwithstanding, however, the prompt treatment which had been adopted, the young lady's sufferings continued to increase, and she expired, in little more than twelve hours from the commencement of the attack.

As there was considerable mystery hanging about this case, as to the cause of the symptoms, their severity, and the suddenness of the attack, it was thought more satisfactory to make a *post mortem* examination. The abdomen was exceedingly tumid and resonant. On laying it open, the stomach and intestines appeared distended with flatus, and presented all the signs of incipient enteritis. The stomach felt somewhat hard, and its larger curvature was considerably discoloured. An opening made into its cavity at once explained the cause of all the symptoms during life. There was a mass of *unbroken* cherry-stones, which seemed, as it were, cemented together with other matter, completely blocking up any outlet by the pyloric portion. It was then recollected that Miss K. had eaten very heartily of some ripe cherries, with other *bonbons*, during the evening, and had foolishly neglected to cast away the stones. There was a mass of nearly a pound of these indigestible substances. It is difficult to learn whether anything more could have been done to save this lady's life; but a question suggests itself,—Would a powerful emetic have dislodged the foreign mass, had we been aware of its existence?

CASE IV. Elizabeth Barnett, a healthy-looking child, ten years of age, began to complain of great pain in her bowels, particularly at the lower part of the abdomen, on the right side. There were all the symptoms of intestinal obstruction present: obstinate constipation, with nausea, and vomiting of bilious matter. Pyrexia prevailed, the pulse being 120 and upwards. The pain at first appeared to be circumscribed; but, as the case advanced, the abdomen became exceedingly tumid, and was tender to the touch. Calomel, mixed with sugar, was given in small doses, with castor oil, etc. Leeches were applied over the seat of pain, with hot fomentations, etc.: but everything proved abortive, either to procure evacuations, or relieve the child's sufferings. She died on the third day. Permission was granted to examine the body. On reflecting back the abdominal parietes, the small intestines were found to be greatly distended with flatus, and exhibited patches of inflammation. A further search discovered that a kidney-bean had slipped into the appendix cæci: it had swollen considerably, in consequence of its locality, and caused inflammation of the appendix. This had extended to other portions of the intestines, and invincible obstruction was the direct consequence. The appendix had lost its usual curved form, from the bean having got into it as far as half its length.

REMARKS. In this case, it would appear, no medicinal treatment could be of any avail, and the diagnosis would necessarily be difficult and uncertain. The question, however, here suggests itself,—Suppose the cause of the obstruction could have been distinctly traced during life, would it have been safe, and should we have gained anything, by making an early opening through the *linea semilunaris*, and, by gentle manipulation, trying to dislodge the foreign body, and place it in the axis of the canal?

CASE V. Mr. David Ferriman, of Wymeswold, aged 45, a painter and stone engraver, having been out on business, in the month of January, 1829, called, late in the evening, on his return, at an inn for a glass of ale. He took out his purse to pay for it, and it appears that there were some loose characters sitting in the bar, who, observing Mr. F. had a sum of money in his possession, waylaid him after he had left the house. He was robbed of his money, and also his watch. The night was dark. The alarm created, however, was so great, that Mr. F. had no power to offer the slightest resistance; and such was the effect produced on his mind, that although he met two or three persons shortly afterwards, and even passed close by the residence of a magistrate, he could make no complaint. He was so confounded, that after he reached home, a length of time elapsed before he could be induced to give any account of what had happened. The shock, however, was too much,—so great as to interrupt some of the functions which are necessary for the preservation of life. There were no alvine evacuations afterwards. Intussusception had evidently taken place. There was, however, no real amount of positive suffering, except at long intervals. As the case advanced, the abdomen became exceedingly tumid, and there was occasional vomiting of bilious matter. The pulse continued steady nearly throughout: the tongue was thickly coated. Hot fomentations were repeatedly applied to the abdomen. Nearly all the list of purgatives had been tried, and quicksilver, with the administration of enemata, simple, as well as of tobacco, but without avail. The abdomen became tympanitic; hiccup supervened, with cold sweats, and death closed the scene on the fifth or sixth day. No *post mortem* examination was permitted.

CASE VI. Mr. William Peat, aged 50 years, a farmer, who resided about two miles distant, had always enjoyed excellent health. He rose as usual in the month of January, three or four years ago; and being a man of active habits, began to sweep away the snow which had fallen heavily during the night. The weather had been excessively cold, and a pond was frozen over where the cattle were wont to drink. Mr. P. was in the act of breaking the ice with a crow-bar, when he was suddenly seized with a severe attack of diarrhoea, attended with considerable

gripping. In a short time afterwards, I was summoned to attend Mr. P., and when I entered his room, he was writhing with agony. He bent his body forward; his hands were placed on the lower part of the abdomen, on the right side. He described the pain as being just above the inguinal opening, and as if his "*bowels were being torn asunder.*" The symptoms were such as usually accompany a case of strangulated hernia; but a careful examination showed that the abdominal openings were quite free. There was urgent tenesmus, attended with nausea, but without vomiting; the pulse beating about 80, and feeble. Fearing inflammation, I took away fourteen ounces of blood from the arm, gave four grains of the chloride of mercury and ten grains of extract of colocynth, with repeated doses of castor-oil; but it was clear I had to contend with an invincible obstruction in the intestinal tube. Fomentations to the abdomen were constantly applied, and enemata were administered. The severity of the symptoms and pain continued unmitigated; no evacuations took place; and the patient expired at about nine o'clock the same evening, being about thirteen hours only from the commencement of the attack.

REMARKS. No examination was here permitted after death; but the fact of the patient having risen in his usual state of good health,—the sudden, yet severe attack of diarrhoea, succeeded immediately by intense pain in the lower part of the abdomen, on the right side, and circumscribed, without the least trace of hernia, convinced me that the case was one of intussusception, or internal strangulation, certainly terminating in an extraordinarily rapid manner. That the whole of the symptoms arose from cold, if the case was one of intussusception, there appears little doubt, the patient having, on the day previous, being very thinly clad, been exposed to a bitter cold north wind. It is well known that cold will bring on diarrhoea; and, spasm ensuing, intussusception will frequently follow.

CASE VII. About thirteen or fourteen months ago, I was requested to attend on Ann Kinton, aged 44 years, and the mother of a numerous family. I found her in bed on my arrival. She complained of great pain and fulness in the abdomen. There was frequent tenesmus, but it appeared there had been no evacuation during several days past, except a very small one, which was scybalated, and effected by very hard straining, attended with great pain. I learned there had been a constipated condition of the bowels for about two years, and that defæcation had never been effected without considerable suffering, and only once in seven or eight days; that latterly each stool had been of a very flattened shape, and frequently streaked with blood. Before this woman sent for me, she had taken a large dose of Epsom salts and infusion of senna, as well as some castor oil, but without the slightest relief, since no evacuations were procured, and the pain became severe. There was now constant nausea, without vomiting. The skin was cool, and the pulse beat 73, full, yet soft; the tongue was much coated, but moist. The abdomen was very large and resonant, without tenderness on making gentle pressure. The pain in the abdominal region was not now very distressing, and only occurred at long intervals. Still there were great restlessness and uneasiness, attended with an aching sensation across the lumbar region, and extending along the course of the sacrum. I prescribed chloride of mercury, combined with extract of colocynth and croton oil, besides the black draught. The vomiting, however, became more urgent, and thinking this might arise from the croton oil, I now omitted this, and the patient was directed to take no aperient except small and repeated doses of castor oil. Enemata were repeatedly administered: and two grains of calomel, combined with one grain and a half of opium, were given at bed-time. As no evacuations had been procured on the tenth day, I wished to try the effect of a tobacco enema, and I waited some hours to watch the result. There was the usual symptom of great prostration of the vital powers produced by this enema, but nothing passed off by the bowels except what had been injected *per anum*. It was now evident that some mechanical obstruction existed; but a digital examination detected nothing.

the rectum. If there existed a constriction in this part, it was higher than the finger could reach. When a small-sized bougie was attempted to be introduced, it met with resistance about six or seven inches high. Different sized bougies were carefully tried, but with the like result,—each became coiled, if much pressure was used. The patient's friends now wished to have the opinion of Dr. J. C. Williams, of Nottingham. This gentleman saw the woman on the evening of the 21st of August, 1851; there were no very urgent symptoms. All attempts, however, to give an enema proved ineffectual; it passed no further than the constriction. On the following morning, after Dr. Williams had seen the patient, I was resolved to try the introduction of O'Beirne's tube; it, however, met with the same resistance the other instruments had done, and returned in a coiled form. When I repeated my visit in the evening of the same day, to my great surprise, the poor woman stood looking out of her window, and said, "*I am taking another look round before I go, for I am dying in health.*" She then sat up, and took some tea with her family. As Dr. Williams had seen her, she now expressed a wish to try whether any thing more could be done for her if she went to the Nottingham General Hospital, and asked me if I should object to this, and whether it would be safe for her to risk the journey, a distance of ten miles. Of course, to gratify her wish, I assented, provided she travelled in a covered conveyance, on a bed or mattress; at the same time, I assured her that little more could be done by medicine. On the following day she was no worse, and her wish was gratified by her being admitted into the Nottingham General Hospital. A consultation took place, and I believe attempts were made to pass some bougies, etc. Unexpectedly, however, on the following day, the poor woman ceased to breathe. No evacuation had been procured. Hearing of her death, I felt naturally anxious to know whether a *post mortem* examination had taken place, and if so, what were the appearances of the intestinal tube. Accordingly, I wrote to Dr. Williams, and received his reply, with an inclosed description of the morbid appearances. The following is a copy of a letter written by Joseph White, Esq., the resident surgeon of the hospital:—

"In the case of Mrs. Kinfon the principal seat of stricture was in the rectum, about seven inches from the anal extremity; a smaller amount of contraction existed lower down, though this was easily passable. The colon was ulcerated in patches throughout the greater part of its length; though most extensively in the transverse portion. The other viscera were all healthy. The stricture would with difficulty admit the point of the little finger; and the bowel immediately above was thickened and corrugated, so as to form a valve, preventing the passage of any matter downwards."

CASE VIII. Samuel Marshall, aged 60 years, a bricklayer by trade, was suddenly seized with all the severe symptoms which accompany a case of strangulated hernia. His sufferings appeared horrible. He threw himself on the floor, and rolled about in agony; then he would as quickly rise, with his hands firmly pressed on the lower part of the abdomen; but no position or place gave him the slightest relief. He never had had hernia, but had frequently felt some severe cutting pains along the abdomen. Calomel, castor oil, and calomel combined with a full dose of opium, were given. Enemata were administered; no relief, however, was obtained; the symptoms presented a darker aspect, and the man died in less than twenty hours of intense suffering. An examination after death showed a constricted condition of the intestinal tube near the caput cæcum coli. This, it appeared, had been progressing for some years past, and fresh morbid matter being continually laid down, a tough and constricted band had been formed, which gradually becoming closer, strangulation of the gut ensued.

CASE IX. A few months ago, I attended a case of intestinal obstruction, arising from internal strangulation. A young woman had for several months before complained of cutting pains across the umbilical region. When I was summoned to visit her, there was considerable nausea, accompanied with

occasional severe pain in the abdominal region, and which extended downwards. I learned that she had been confined to her bed for more than a week before I was requested to see her; she had taken castor oil of her own accord; a few days before she took the oil, she had a severe attack of diarrhoea attended with much pain. She informed me that she had frequently felt a dense pain in the lower part of the abdomen, on the right side, and that constipation had prevailed to a considerable extent. There was now considerable tenderness from the right hypochondrium downwards, but without the least tumidity of the abdomen. I could distinctly feel a circumscribed hardness nearly opposite the cæcum, or descending portion of the colon; and it was evident that the locality of the obstruction was in or near to these parts. It was, however, with the greatest difficulty that an enema pipe could be introduced up the rectum, and very little injection would pass, being quickly returned. The mildest aperients, and calomel combined with opium, were given. To attempt an operation, as suggested in another part of my paper, even if in other respects it might appear practicable, in this instance was forbidden by the symptoms. Death occurred early on the third day after I first saw the patient. A *post mortem* examination proved that a portion of the descending colon was constricted by a firm band of lymph not of recent formation, and the appendix cæci had become attached at its extremity to the descending portion of the colon, and formed a ring, through which a portion of the ileum had passed and became strangulated. In most of these cases the abdomen is considerably resonant and tympanitic, but in this instance it was perfectly flat.

Wymeswold, Leicestershire, February 1853.

THE CLIMATES OF THE WORLD, IN REFERENCE TO THEIR EFFECTS ON MAN'S GENERAL WELFARE AND DESTINY.

By T. G. HAKE, M.D., Physician to the Suffolk General Hospital.

At the present hour, when millions of human beings are leaving their homes in Europe, or contemplate doing so, for countries which may or may not possess a climate similar to that which gave them birth, it cannot fail to be perceived that many interesting inquiries are thereby laid open to science, on which none but the physiologist can enter with advantage.

If the race of man, then, in all its varieties, affords a general expression of the existing climates of the world, in reference to the circumstances which contribute to healthy organisation; if one climate maintains, while another modifies more or less the characteristics of human beings, as is undoubtedly the case, it cannot be out of season to make this investigation: With what result to his own physical conformation and moral character, and more especially to that of his descendants does man, born in a congenial climate, emigrate at random into different zones?

Having examined this subject in its many bearings, both by collating the written observations of travellers made cursorily without any immediate scientific object, and by questioning intelligent persons from our colonies, and other newly formed states, I premise with confidence that it is one which is most important and curious. To take a common example;—What a diversity of effects must obviously arise from one member of a family taking up his permanent abode in a portion of the American, and another in a part of the Australasian continent. Both regions afford climates which are called delightful and healthy; but their separate influence on the organisation of the European is already perceptible. Indeed, it has been forcibly argued that man cannot travel out of his own zone without entailing extinction on his race. Be this as it may, an inquiry into the subject of isogenetic*

* I venture to introduce this term in order to mark the distinction between zones of equal gentility of climate, and those of like temperature, or isothermal zones, both of which differ from each other, and from geographical zones, as much as the magnetic differs from the common equator.

or congenial zones is of sufficient moment, under the existing conditions and inevitable redistribution of nations, to give basis to a branch of science; nor will it be passed over without due consideration in this series of papers.

The classical ethnographer is of opinion, that the human race is essentially migratory; that while it has enjoyed the character of being so from its origin, it is in obedience to the same instinct that it persists in pursuing its migrations into lands still unsubdued or unpeopled. But if it were true originally that the human race, being of common stock, fulfilled one of its great ends in spreading itself over continents, does it follow that the physical conformation of man is calculated to endure these changes of climate indefinitely? The race of man, physiologically considered, has its limits, like animal beings generally, many species of which have disappeared, some within our own time. Granting then, that after one or more migrations a particular race has become acclimated, as the Saxon, the Dane, and the Norman in this country, is it to be supposed that further migration, beyond our isogenetic zone, is in accordance with natural laws, especially at this not early period of human history, when disease to so large an extent is hereditary, and early death so general, as to mark an epoch in man's limited career?

In answer to these inquiries it may be assumed, that the type of man's physiological condition is expansive to a great degree, and that change of character in it is not incompatible with its integrity; but that, beyond certain limits, such change as is effected by diversity of climate does hasten the fulfilment of the natural law of its extinction.

With these preliminary remarks, the subjects intended for discussion may be approached in detail.

Climate, it will be found, is intimately associated with the history of countries. The Olympic games, the Greek drama, in common with the arts both of architecture and sculpture, are in some degree due to the influence of a cloudless sky. Rome owed her exterior splendours, Italy her palaces and unrivalled frescoes, to the same southern clime; while the vivacious Frank, rejoicing in an atmosphere scarcely less pure, delights in the imitation of Athenian taste and Roman example, with their avenues, statues, and fountains. But the Englishman, enjoying equal, if not greater advantages, all of which are due to the climate of his native country, appeals neither to sun nor sky; he is content to expatiate on the luxuriant verdure of his fields and hedgerows—on the perfection of his stock—on the breed of his cattle—on the manly character of his countrymen: and for the rest, he exercises his privilege of grumbling, however unjustly, at the ever-varying weather and leaden sky, through which these unexampled benefits are maintained.

What meaning, then, is to be attached to the expression, *a good climate*, in the widest acceptation of the phrase? Though the sun of Greece may have inspired the dream of an Acropolis, and its realization; and somewhat later, but in the same spirit, may have marked out the boundaries of an eternal city on the plains of Italy,—of what avail is it, if human welfare prove not commensurate in duration with the glories of Nature? But so it is; the greatness of the South has been due to other causes than climate: it has arisen from a combination of human elements, the admixture of races having mainly contributed to the great result, the enduring monuments of which, climate alone was unable to sustain. Yet, that some climates are better suited than others to the development of man—to the formation of his genius—to the growth of his physical powers—to the production of his supplies—is scarcely to be disputed. What country or region, then, beyond all others, has proved the most congenial to man;—and in what does its geniality consist?

Excellence of climate is that quality which secures to any country its aptitude for the maintenance of intellect, strength, and health in the highest perfection, and for the rearing and growth of the supplies best adapted to the support of man. Some may, at first sight, pronounce this

definition to be too strictly economical—too exclusive of the pleasures derivable from sunshine and a perpetual spring. But who can dispute the supreme blessing of health? And when this is once admitted, it cannot but be allowed that food, one of its chief sources, must take a prominent place also among human benefits.

Nevertheless, it is highly probable that the custom of undervaluing—indeed, abusing this climate, boasts a high antiquity. King Charles the First, with true discrimination, was among those who saw the subject in its true light: he observed, that in no other country was it possible to take exercise in the open air for so many days during the year as in England. And yet it has been reserved for the nineteenth century—that epoch of our scientific agriculture, of our success in sciences, in mechanical arts, in all that has its source in the intellect and energy of man,—to discover in how great a degree all this is due to climate.

Looking to exercise then as one grand source of health, let it be considered how many fine days, or portions of fine days, occur in all parts of England, however diversified, during the year. To the advantage our temperate climate thus affords, are attributable the vigour and symmetry of the men, and the corresponding beauty and freshness of our women. What other country boasts its pedestrians, who have accomplished the feat of walking over a thousand miles in a thousand hours? Where else are we to look for a race of prize-fighters like that which, through moral, not physical influences, is now disappearing? To descend in the scale, to what but to the climate of this country is the perfection of the horse attributable; and not of the horse only, but every other kind of animal?

As a grazing and agricultural country, England can scarcely be surpassed; but it is unnecessary to do more than allude to the produce of her soil, whether vegetable or animal. If the superior excellence of our stock is attributable in the first instance to breed, no other influence than the climate could have perpetuated it; for the same stock, imported into less favourable regions, is known to deteriorate rapidly.

This utilitarian view may appear novel to those who have been in the habit of associating the spontaneous productions of the earth, and a perennial spring, with all that is desirable in climate,—who, unaccustomed to the details of science, fall readily into the luxurious dream of the poet, in crediting the idea that the man of temperate zones can with impunity settle down within intertropical countries. But the true tests of a climate are seen in the quality of its productions; the constitution and temperament of the people living under it; the age to which they attain; and other circumstances of a like character, to which reference will be hereafter made.

This country owes its productiveness to the somewhat equable fall of rain which occurs throughout the seasons; to the moisture and warmth preserved to the land by a clouded atmosphere, which, by preventing a radiation of heat from the surface, tends materially to neutralise the effects which would else accrue from a high latitude. But these circumstances alone, while they might preserve it from becoming ice-bound during winter, like other countries of the same, and of still more southern latitudes, are not sufficient in themselves to create the truly temperate climate we inhabit; other causes, of a most admirable and unique description, are to be looked to, not only in characterizing our zone, but in extending its geographical boundary over a great part of Europe.

A lake of warm water, having a maximum temperature of 86° Fahr. in the Strait of Florida, stretches across the Atlantic, from Cape Hatteras to the Azores; it greatest breadth being 120 miles, and its entire extent equal to that of the Mediterranean Sea. The origin of this tepid lake, whose waters are directed ultimately to our coast, and the western shores of Europe, is the Gulf of Mexico—an enormous cauldron, measuring one thousand miles in length, and seven hundred in breadth; having above it a tropical sun, which maintains a very high temperature in its waters.

From this great sea, both the name and source of the Gulf Stream are derived. After passing between Cuba and Florida, and taking the direction of the American coast, it turns eastward, preserving a mean velocity, from the commencement of its course to the Azores, of 38 miles a day; having a temperature of about 9° Fahr. above that of the surrounding ocean in the Strait of Florida, which decreases so gradually in its passage to the east, as to have lost only 5° Fahr. Opposite the south bank of Newfoundland, a distance of 1,300 miles, it still retains a heat of 8° or 10° above that of the adjacent seas, communicating its temperature to the superincumbent atmosphere.

The warmth diffused over the Atlantic Ocean by this means would be sufficient—such is the calculation—to raise the entire column of air covering France and the British Isles, on a winter day, from freezing point to summer heat—a fact which accounts for the comparative absence of ice in the North seas, and affords the true explanation of the mildness of our climate, and that of adjacent countries.

But, while its influence, by means of the atmosphere, thus affects a large extent of climate, the Gulf Stream itself washes our western shores. The waters of the Atlantic are still warm as they wash the coasts of Connaught, while their effect is perceptible along the shores of Norway, and to the very borders of the Arctic Ocean.

And lastly, among the tributaries of our temperate climate, is the south-west current of air, which is the prevalent wind of the northern hemisphere. Its gusts occupy the track of the Gulf Stream. They waft the warm moist air, arising from the contact and evaporation of its waters, over the coasts of Western Europe; they are felt in the same warm fitful gusts, from Cape Finisterre to the North Cape, as in the Atlantic, penetrating into the Baltic, and reaching to the Russian plains. It is the influence of this current which gives to the western coasts of these islands, from Cornwall to the Hebrides, almost the same isothermal line.

Bury St. Edmunds, Suffolk, January 1853.

CASES OCCURRING IN THE MEDICAL PRACTICE OF THE SUSSEX COUNTY HOSPITAL DURING THE YEARS 1849, 1850, AND 1851; WITH REMARKS.

By G. S. JENKS, M.D., one of the Physicians to that Institution.

(Concluded from p. 104 of last number.)

DISEASES OF THE HEART AND BLOOD-VESSELS.

In 1849, a case of very extensive disease of the heart was admitted, accompanied with distressing orthopnoea and oedema of the lungs. The man survived only two days. In early life, he had had acute rheumatism, afterwards chorea; and, five years before admission, he had undergone another severe attack of rheumatic fever.

Autopsy. The sternum was observed to be prominent. Old adhesions of the pleurae of the bases of the lungs to the diaphragm were found. Serous effusion had taken place on both sides; nearly a quart on the right, and about a pint on the left. The lungs were oedematous throughout, constituting the serous apoplexy of the lungs of authors. The heart was very large; the pericardium universally adherent. The right side of the heart was healthy, except some fatty degeneration at the apex of the ventricle. On the left side, there was great excentric hypertrophy. The mitral valve was thickened and rigid. The aortic valves were also much thickened and rigid, and so bound down as to have admitted of regurgitation. The endocardium presented a good-sized white patch just below the aortic valves. The abdominal viscera were healthy. The head was not examined.

In 1850, the following cases occurred:—

CASE. Esther Cain, aged 21, after a tedious and imperfect recovery from acute rheumatism, was admitted in an anemic state; whether as a result of that disease, or of the suppression of the catamenia, is doubtful. There was disease

of the mitral valve, indicated by a loud, harsh murmur. The albuminous state of the urine led us to suspect also disease of the kidney. She died from anasarca and bronchitis.

Autopsy. Fluid was found both in the pleural and peritoneal sacs. The lungs were oedematous. There was an adherent pericardium, easily separable in the front and at the apex. The heart was large and flabby. Attached to the free edges of the mitral valve, were some wart-like excrescences, apparently not of long standing. The kidneys were large, pale, and firm; the capsules peeled off easily, disclosing the parenchyma, intersected by reddish streaks, giving it a mottled appearance. The liver was healthy.

CASE. Benjamin Emery, aged 67, had been ill for six weeks. He suffered from dyspnoea, palpitation, pain in the right arm, together with pain in the hepatic region, and much oppression in both hypochondria. The countenance was anxious; the pulse jerking and resisting. There was a musical murmur with the second sound of the heart. It was not agreed what this proceeded from; but I suspect there was some aortic regurgitation, from the character of the pulse. Under the use of blue pill with squills and digitalis, and a diuretic draught, the congestion of the liver and spleen was removed, and the dyspnoea greatly relieved.

Two girls, of the respective ages of 16 and 20, were under treatment for disease of the mitral valve, produced by acute rheumatism. Both suffered from dyspnoea and palpitation; and in both the heart was enlarged. They left the hospital much relieved. The younger one died, I am told, not long since, in the country.

I cannot help here reverting to the fact, so often presenting itself, of very young subjects, especially females, being affected with disease of the heart as a result of acute rheumatism. We have here three bad examples; and we shall find that, out of three cases of acute rheumatism admitted in 1850, two—one a girl of 18, the other a youth of 20—had symptoms of endocarditis; while a man of 46 had no cardiac symptoms whatever.

In 1851, a case of hypertrophy in a woman aged 51, without signs of valvular disease, was admitted. Palpitation was constant, but under exertion it became vehement and distressing. There was a whizzing sound with the pulse, high up beneath the sternum, which made me suspect dilatation of the arch of the aorta.

Another case, in a girl aged 13, was of a very serious character. It had been originally brought on by a severe attack of acute rheumatism. There was a loud endocardial murmur at the base. The heart was enlarged. Pain, palpitation, and dyspnoea, were induced by exertion.

DISEASES OF THE ORGANS OF DIGESTION.

GASTRO-ENTERITIS. A case of this description, admitted in the year 1849, has been already described under the head of tubercular diseases.

In 1850, a case of gastro-enteritis, with severe and protracted diarrhoea, in a scrofulous female, aged 28, terminated fatally. An examination of the body was not permitted. From the history and concomitant symptoms, there was reason to regard this case as one of intestinal tuberculosis.

DYSPEPSIA. In 1851, twenty-one cases were admitted under this head; fifteen occurring in females. In some instances, the symptoms exhibited a sub-inflammatory character. There were total anorexia, nausea, a dry red tongue and fauces, a sense of heat internally, and diarrhoea or constipation, with epigastric or abdominal tenderness. These cases were relieved by the application of leeches to the seat of tenderness or pain, followed by blisters. Effervescing draughts with hydrocyanic acid, and cold acidulated drinks or ice, are useful. When the inflammatory symptoms are subdued, mild mercurials and purgatives restore the healthy action of the secreting and excreting organs; and due attention to diet completes the cure.

Dyspepsia with gastrodynia and pyrosis is common. Pain in the stomach after taking food, in women of a leucoplegmatic temperament, with or without leucorrhoea as a

concurrent affection, is, with few exceptions, soon relieved by bismuth. I usually prescribe a powder with from five to ten grains of nitrate of bismuth, ten or fifteen grains of carbonate of magnesia, and three or four grains of compound powder of kino. The bismuth, in these non-inflammatory cases, appears to have the effect of freeing the stomach from its morbid sensibility, and of restoring its normal action. Emetics are often of great use. When leucorrhœa exists to any extent, the infusion of quassia, with sulphate of zinc, is of good service. Pyrosis, in subjects beyond the middle period of life, or of advanced age, should be regarded with suspicion. It is often connected with organic lesions.

HÆMATEMESIS. A case of hæmatemesis, which occurred in 1851, deserves mention on two accounts: first, by reason of the great loss of blood, which nearly extinguished life; and next, on account of the effect of remedies.

CASE. — Sibney, aged 42, a nurse in a family, was admitted May 25th. Five years ago, she was ill seven weeks with vomiting and severe epigastric pain, supposed to indicate disease of the liver. About four months since, she was seized with pain at the pit of the stomach, followed by vomiting of blood to the extent of a pint and a half, as reported; and had several fainting fits in consequence. This attack was succeeded by a weekly discharge of blood from piles, which greatly reduced her strength. On the day of her admission, May 25th, she had suffered a great loss of blood by vomiting. Her bowels having been obstinately confined for some time, the house-surgeon's first care was to remove this impediment. Next day, gallic and sulphuric acids were ordered, with ice and iced drinks, etc. In the evening, two drachms of oleum terebinthinæ were given.

May 27th. Much the same. The following draught was ordered:—*R. Plumbi diacetatis gr. ij; aceti destillati 3j; aquæ dest. 3xj. Fiat haustus 2dis vel 4tis horis sumendus.* In the evening, the vomiting of blood continuing, she was for two hours in a state of extreme syncope, requiring wine and ammonia, and the application of hot sinapisms to the epigastrium, chest, and extremities. When she had somewhat recovered, another dose of turpentine was administered.

May 28th. Some blood was still vomited, though less copiously. Her exhaustion was extreme. Wine, and the best nourishment she could take, were ordered; and the following draught was prescribed:—*R. Olei terebinthinæ ℥x, ex ovi vitello; tinct. matico 3ss; aquæ pimentæ 3iss. M. Fiat haustus 3tiâ quâque horâ sumendus.* A blister was applied to the epigastrium.

May 29th. No return of hæmorrhage had taken place since last report, which, indeed, was the last time it occurred. She remained in hospital till July 9th, when she was discharged convalescent.

The quantity of blood lost by this woman must have amounted to several pints. There were no evident signs of hepatic disease; but, as blood had been discharged by the hæmorrhoidal vessels, as well as by the stomach, some obstruction of the vena portæ probably existed. Are we to attribute the suppression of the hæmorrhage to the matico? I have not much experience of the effect of this remedy administered internally.

CHRONIC VOMITING. A very obstinate case of chronic vomiting occurred in a young woman, a cook, aged 26. She had suffered for some years with heartburn, pyrosis, and gastrodynia, now and then attended with obstinate vomiting, for which she had been in a London hospital. She was admitted December 17th, having already been ill three weeks. Her appetite was good, but she vomited nearly the whole of her food (without much nausea) in a semi-digested state, mixed with mucus, sometimes with bile, and now and then with some blackish matter. The catamenia were regular; the tongue pale and flabby; the bowels were moved with difficulty, even by the most active purgatives. She was not otherwise ill. She was under treatment for two months. Effervescing draughts with hydrocyanic acid, ice, creasote, bismuth, opium, dilute sulphuric acid with sulphate of

magnesia and infusion of hops, strong purgatives, and enemas, failed in checking the vomiting. The only thing which relieved her, and effectually stopped the vomiting, was a pill with seven grains of Barbadoes aloes and one minim of undiluted sulphuric acid, taken once or twice a day. This opened the bowels freely and regularly. She was able, while taking it, to retain all her food, and became plump and fat.

INTESTINAL OBSTRUCTION. The following case, admitted in 1850, was interesting in many respects:—

CASE. Eliz. Stagle, aged 61, of a corpulent habit, was admitted March 30th. Her illness began a month before admission. At first, she was seized with severe pain in the bowels, vomiting, and obstinate constipation. By the report of the medical attendant, stercoraceous vomiting ensued. At length, however, the bowels were relieved; but sickness, pain, and great distension from flatulence, remained. She was nearly eight weeks in hospital, which, added to the time she was under treatment out of the house, made the duration of her illness little short of twelve weeks. Notwithstanding the evidence of very serious and obstinate obstruction of the bowels at the commencement of the attack, she suffered from uncontrollable diarrhœa all the while she was in hospital. The distension from flatulence for some time was enormous, but at length seemed to yield to large doses of camphor. She was in constant pain, and at no time could bear pressure in the left iliac region without complaint. She had a return of stercoraceous vomiting in the last week of her existence; the diarrhœa persisting. An erysipelatous inflammation of the mouth and fauces came on, with sloughing of the soft palate. She died May 22nd.

Autopsy. On examining the intestines, the colon, just above the sigmoid flexure, was found firmly agglutinated to the ileum. Around the colon was a thickened mass, which on section appeared to be composed of distinct collections of soft yellow matter. Within the colon were displayed, from above downwards, large ragged ulcers; the mucous membrane being destroyed to a great extent. At the point of agglutination to the ileum, were many fistulous passages; the proper canal of the intestines seeming nearly obliterated. One of these ragged, fistulous openings, larger than the rest, ran from the cavity of the colon into that of the ileum. Below this, the mucous membrane of the colon was healthy. The mucous membrane of the ileum was thickly set with small round ulcers on both sides of the perforation. There were also fatty liver, diseased kidneys, and a fibrous tumour of the uterus.

DISEASES OF THE URINARY ORGANS.

ALBUMINURIA. In 1849, two cases occurred, both in women.

CASE. Catharine Turrell, aged 18, was admitted on Jan. 31st. About two months before, she had been discharged from the hospital, having been eight weeks under treatment for amenorrhœa. She was rather fat, and of a florid complexion. The catamenia had not appeared for five weeks, and then very sparingly. Her chief complaint now was of severe pain in the loins, which impeded her movements. There was much tenderness on pressure on each side of the spine, in the region of the kidneys. The pulse was of moderate frequency and strength; the tongue clean; the bowels open. She passed a large quantity of pale urine, which on examination was acid, of specific gravity 1·010, and abundantly albuminous. The pain of the back was greatly relieved by cupping. Towards the end of February, the urine was less abundant, of specific gravity 1·020, but still albuminous as before. Anasarca of the lower extremities now first appeared. About the middle of March, the abdomen began to enlarge. The urine became thick and muddy, from a copious deposit of the lithates. The specific gravity rose to 1·026, at which point it remained till the middle of April, when it fell to 1·015, and afterwards, in July, to 1·005, without any remarkable increase in quantity. The anasarca went on increasing till it had invaded the cellular tissue of the loins and lower part of the abdomen.

It became necessary to puncture the legs and thighs, to prevent cracks and ulcerations of the over distended skin. In the month of June, fluctuation was very evident in the abdomen. About the end of July, profuse diarrhoea set in, which, though restrained and moderated by remedies, was never wholly suppressed. The mouth became very sore from aphthae. The dropsical symptoms gradually but wholly disappeared at least ten days before death; the serous exudation process having been transferred to the bowels. She died from exhaustion, Sep. 20th.

Autopsy. The head was not examined. The right pleura had several old adhesions. The apices of both lungs presented several tubercular deposits. The heart was small, but healthy. The great omentum was adherent at each ring. The mucous membrane of the intestines had several patches of intense congestion, but no ulcerations. The liver had undergone fatty degeneration. Both kidneys were very much enlarged; their structure was much confused with a whitish deposit. Numerous stellate veins were observed on their surfaces. A scrofulous abscess was found in the fundus of the uterus. The left ovary was enlarged, adhered to the uterus, and contained scrofulous matter. The state of the right ovary was not noted; but my impression is, that it also adhered to the uterus, and had undergone similar disorganisation to the left one. Enough, however, was found to explain the persistent amenorrhoea.

This case of albuminuria nearly corresponds to Rokitsansky's third form of Bright's disease, which is frequently fatal; but it will perhaps occur, that there was no proportionate relation between the changes of structure in the kidney and the great amount of albuminuria and other morbid processes. But, in fact, the renal change of structure is not the cause of *all* the morbid states, nor even a measure of their intensity. Rokitsansky, Walshe, and others, look upon Bright's disease as primarily a disease of the blood, the anomalous condition of which fluid has a peculiar relation to the kidney, and is followed by the secondary and visible disorganisation of the renal tissue. As the deposition goes on increasing in the kidneys, the excretory function of those organs becomes partly mechanically and partly dynamically interfered with; and hence the blood acquires a secondary morbid crasis. Rokitsansky thinks that albuminuria consists in a disturbance of the catalytic function of the kidney, arising from the homologous infiltration of the renal tissue. Albumen is in part deposited in the channels of the tubuli themselves. Albuminuria and granular kidney, however, are not necessarily associated; for the former may exist without the latter.

Regarding Bright's disease as having its origin in the blood, it may be asked why it affects the kidney? This question will admit of an answer, probably, when we can explain why tubercle is chiefly attracted to the lungs, cancer to the mamma and uterus, gout and rheumatism to the joints. This primary morbid condition of the blood, whatever it may be, there is little doubt, is generated in the body, and, like the diseases just mentioned, arises from some constitutional predisposition to these imperfect organic processes, without which none of the supposed causes of Bright's disease would produce it.*

The peculiarities of the blood in Bright's disease, as ascertained by analysis, are abundant serum of low specific gravity, excess of fat, excess of urea, and deficiency of albumen; but they are probably secondary. Rokitsansky thinks that the nature of the renal affection in this disease consists of an inflammatory process, which proceeds from a stage of hyperæmia to one of stasis, and then gives rise to the peculiar product which accumulates in and alters the appearance and structure of the kidney. It is sometimes acute, but generally chronic, with occasional exacerbations. The granulations are the Malpighian bodies and urinary tubuli charged with the above-named product.†

* Some pathologists, however, of high authority in our own country, as Drs. Owen Rees, Todd, and G. Johnson, are of opinion that Bright's disease is a fatty degeneration of the kidneys.

† An excellent monograph on the nature and treatment of Bright's disease was published by Frerichs in 1861.

The treatment of this case was directed, in the first instance, to subdue the acute symptoms, by moderate cupping, purgatives, diaphoretics, the vapour bath, etc. In the chronic stage, recourse was had to various preparations of iron, diuretics, hydragogue cathartics, etc. At length, the diarrhoea, and the extreme debility thereby induced, demanded all the assistance of art, in order that we might relieve, since we could not cure our patient.

CASE. The other case of albuminuria occurred in a woman, 31 years of age, unmarried, and following the occupation of a nurse. She said she had been long subject to giddiness and shortness of breath, with much wheezing, but no cough. Two days before admission, she was seized, while blowing her nose, with violent pain in the head, which went on with increasing intensity, and formed her chief complaint. She had vomited several times, and felt constant nausea. Before admission, she had taken calomel and purgative medicine, and leeches had been applied behind the left ear. Pulse irregular; respiration asthmatic and feeble. Sibilus was general on both sides; but the chest sounded well on percussion. She had abundant leucorrhœa. The urine was highly albuminous. A blister was applied to the nucha, and a draught, with digitalis, squills, and decoctum scoparii comp. was ordered every fourth hour. The next day, the digitalis was omitted, on account of her complaining of great faintness. On the 20th December, six days after admission, the headache was much better, but she complained of severe pain in the loins, and could not bear pressure. She was cupped to six oz., with relief. The following day, a seton was inserted in the nape of the neck.

Dec. 27th. The head and back gave very little pain. The leucorrhœa had ceased. The urine still albuminous in the same degree. Pulse 80, regular. Respiration free.

This woman improved in all respects save the state of the renal secretion, which continued to throw down much albumen, on the application of the usual tests. The seton appeared beneficial, and the diuretics, which acted most beneficially, relieved the chest. She was discharged free from complaint; but albumen was still found in the urine.

In 1850, the following case deserves a detailed notice:—

CASE. Maria Hunt, aged 30, much emaciated, subject to hectic fever, with night sweats, had been ill a year. She suffered severe attacks of pain in the region of the left kidney, passing downwards towards the bladder; and had pain in making water. There was a discharge of pus with the urine. Under the use of the pareira brava and creasote, she gained flesh and strength, and was much relieved. She left the house at her own desire, when there was very little purulent deposit in the urine. Subsequently, while taking balsam of copaiba, a measly-looking rash broke out upon her. She said she had had measles. After this, an attack of pneumonia of the upper lobe of the right lung, of a low, asthenic character, with profuse expectoration of a dark, thin, red matter, not foetid, set in. She quickly sank, and was delirious the day before death.

Autopsy. The left lung was free from adhesions, and contained a few tubercles. The right lung was generally adherent, and the apex was crushed and broken down in the attempt to disengage it. The upper portion of the superior lobe was infiltrated with a dirty, reddish fluid, which exhaled a foetid odour, so that Dr. Ormerod, who made the examination, was of opinion that the disease had proceeded to a gangrenous termination. The lower portion of the same lobe was a greyish, soft, friable mass, yielding some puriform matter when squeezed. The whole lobe contained miliary and chalky tubercles. The right kidney had lost its natural structure, and consisted merely of several sacculi containing a thickish, white, chalky-looking fluid. The ureter was obliterated. The left kidney was large, flabby, with a softened, tubercular deposit at the upper part; while the lower was occupied by a large scrofulous abscess, communicating with the pelvis, which contained some purulent matter. The other abdominal organs were healthy.

In 1851, two cases of albuminuria came under notice.

CASE. A farm labourer, Stephen Wheatley, aged 29, was ad-

mitted in March. He looked pale and bloated, and puffy about the under eye-lids. He was anasarcaous, and had a cough, with difficulty of breathing. There was dulness on percussing both sides of the chest, and abundant fine crepitation arising from oedema of the lungs. The heart-sounds were feeble, but natural. The liver was enlarged. Six months ago, he caught an ague, which only recently had left him. It returned soon after admission, with a quartan type, but was checked after the third paroxysm. The urine was copious and pale, slightly acid, of specific gravity 1.011, and highly albuminous. He took the potassio-tartrate of iron, with bitartrate of potash, every morning. Quinine was prescribed for the ague. Under this treatment, the anasarca was removed, and the respiration rendered easy. He was discharged April 30th, free from cough, dyspnoea, or dropsical symptoms, feeling, as he said, quite well. The urine, when last examined, was of specific gravity 1.018, and much less albuminous.

CASE. Another farm labourer, James Tidy, aged 34, was admitted, with a bloated countenance and puffy eyelids. The parotid and submaxillary glands were swelled. The ankles were oedematous. There was tenderness of the epigastrium and right hypochondrium. His health had been failing for two years. Latterly, he had suffered from palpitations, and a sense of fluttering at the epigastrium. No organic lesion of the heart was manifested. The urine was very albuminous; specific gravity, 1.014. The potassio-tartrate of iron, with the bitartrate of potash, was also prescribed for this man. In the course of a month, he felt so much better, that he returned home. The urine was nearly free from albumen, and the specific gravity had risen to 1.021.

DIABETES. In 1850, two cases of diabetes mellitus came under treatment, with the result of greatly reducing the quantity of urine, and maintaining a correspondence between it and the quantity of liquid taken as drink; so far improving the condition of both patients: but no other change was effected, the saccharine property of the urine remaining unaltered.

In 1851, two cases were admitted. Disulphate of quinine with alum, liquor potassæ arsenitis, and carbonate of ammonia, the last in as large doses as could well be swallowed, were tried. They all moderated the diuresis; but the carbonate of ammonia produced the most decided effect.

DISTENSION OF THE BLADDER. A woman, aged 37, was admitted in the year 1849, six weeks after confinement, with a tumour of the abdomen, resembling the gravid uterus at about the fifth or sixth month of pregnancy. The account she gave of herself was, that the size of the abdomen was not much diminished after parturition. She nursed her child for a fortnight, when her milk left her. A month after her confinement, she was attacked with severe headache, nausea, and vomiting; all which symptoms continued unintermittingly, and with increasing violence, up to the time of her admission into hospital. As there was frequent and difficult micturition, and no enlargement of the uterus could be detected on examination *per vaginam*, Mr. Hodgson passed a catheter, when a large quantity of urine was drawn off, and the tumour wholly disappeared. It was at least a month before the bladder recovered its tone; the urine being alkaline and bloody, and having a muco-purulent sediment.

I have narrated this case on account of the instructive lesson it conveys. The patient had been sent to the hospital from the country, under the belief that she laboured under some organic disease of the uterus—an error into which others might have fallen, who, in like manner, had trusted to external appearances only.

DISEASES OF THE UTERINE ORGANS.

AMENORRHOEA. In 1849, there was a girl, aged 19, who had never menstruated; but for three or four monthly periods there had been decided attacks of fever, lasting about three days. These ceased under treatment, but the catamenia did not appear.

In 1851, seven cases were admitted under the head of amenorrhoea and chlorosis. I have clubbed these affections together, for they are so nearly allied, as to be frequently no more than comparative degrees of the same malady. Amenorrhoea, it is true, is sometimes a mere accident, or depends on a temporary disorder of health; in which case, the function returns when the cause of its arrest is removed. There are cases, again, in which the menses have never appeared at all. Two of the cases referred to were of this kind, occurring in young women, aged respectively 18 and 19 years. In these cases, there is probably some defective development of the sexual organs. I have not met with chlorosis in these subjects. Some pathologists regard chlorosis as primarily a blood-disease, and amenorrhoea merely as a consequence; but I question whether there is not a more intimate relation between the two affections, than a *plus* or *minus* quantity of red corpuscles in the blood. Anæmia often occurs in women, without suppression of the catamenia; and were chlorosis merely a blood-disease, uninfluenced by menstruation, it should occur in males as often as in females. All these cases, complicated with some defect in the healthy crasis of the blood, are cured by preparations of steel. Those which depend on plethora or other causes require corresponding treatment.

RHEUMATIC AFFECTIONS.

LUMBAGO and SCIATICA. A good number of cases were admitted in 1850 and 1851. They yielded almost entirely to absolute rest and topical treatment. Cupping, when the symptoms are acute and recent, afterwards blisters, and a few passes of the hot iron, were found of great service. This is nearly reviving the practice of Cotugno.

SUBACUTE and CHRONIC RHEUMATISM. With regard to the internal treatment, much depends on the constitution of the individual; hence no single remedy will suit all cases. In old cases, and scrofulous habits, cod-liver oil is useful. When there is a suspicion of a syphilitic taint, alternative doses of mercury and iodide of potassium succeed; but in ordinary cases, purgatives, vapour-baths, alkalies, diuretics, and other eliminatives, produce good results. Cupping, blisters, and the hot iron, are also useful external remedies.

CUTANEOUS DISEASES.

PSORIASIS. In 1849, a girl, aged 12, had psoriasis affecting the greater part of the body. Small doses of liquor potassæ arsenitis were given, and she was discharged cured in February 1850, the skin having recovered its natural colour.

SYCOSIS MENTI. In 1850, there was a severe case. In the treatment of this affection, I commonly direct slight scarifications to be made in the inflamed bases of the tubercles: a practice which I have seen adopted in Rome in this disease, and also in bad cases of tinea capitis, with excellent effect.

LEPRA. In 1851, liquor potassæ arsenitis was found beneficial in two cases.

ECZEMA. A man, aged 56, had an eczematous eruption, affecting both legs, with much swelling. The complaint soon yielded to Plummer's pill, and liquor potassæ in decoction of sarsaparilla. Eczema in elderly persons is often a troublesome complaint, and difficult of cure: but one of the most troublesome examples of it occurred in a boy aged 15. The eruption chiefly affected the extremities, particularly the hands, but the trunk did not escape. The subject was robust and healthy; the potash with sarsaparilla failed; the liquor potassæ arsenitis with dilute precipitate ointment succeeded. He was discharged apparently well, April 23rd, having been in hospital fifty-six days; but he subsequently applied as an out patient, suffering from the same complaint.

ERYTHEMA NODOSUM occurred in two females, complicated with rheumatism in one case, and with irregular menstruation in both. Feverish symptoms attended the eruption in both instances.

ACCIDENTAL POISONING WITH CORROSIVE SUBLIMATE.

A case of this kind was brought to the hospital.

it presented some circumstances worthy of notice, I will relate it.

CASE. Henry Godley, aged 23, presented himself, June 17th, with face flushed and eyes suffused, and appeared in a state of great agitation. He breathed with difficulty, and complained of intense burning pain in the throat and in the pit of the stomach. He had inquired, it seems, at a chemist's for something to destroy vermin, with which his person was infested. Now, either not receiving sufficiently clear instructions, or mistaking them, he swallowed a drachm of corrosive sublimate dissolved in half a pint of water, instead of using it as a lotion. He vomited immediately, and probably discharged the greater part of the poison; but was instantly seized with the burning pain above mentioned. Mr. Penfold made him quickly swallow the white of eggs, and copious draughts of milk. Leeches were applied to the epigastrium; and, later, a dose of castor-oil was administered. 18th. The oil had acted: but nothing unusual was observed in the stools. He still suffered internal pain, and complained of soreness of the mouth and throat. The tongue was red; the gums rather spongy; the lips were dry, red, and swollen. Same treatment. 19th. He was feverish, and thirsty; complained of more pain, and burning internally. The epigastrium was tender. More leeches were ordered, and saline effervescing draughts were prescribed. On the 25th he was discharged quite well.

This case exhibits a fair example of the irritant effects of mercurial poisoning. It was a remarkable circumstance that the effects of so large a dose of the poison should have been confined to the mouth, œsophagus, and stomach. There was no diarrhoea, nor any other sign of intestinal irritation; no difficulty of passing water; no ptialism. It may be presumed that this soluble salt of mercury had been converted into a comparatively innocuous compound by the antidotes given for that purpose, and, therefore, those textures only with which it came into immediate contact, suffered from its corrosive action; very little probably having been carried into the circulation.

The above is a condensed report of 490 cases of disease, treated in hospital during the three years mentioned. The deaths amounted to 18, being in the ratio of about 3·6 per cent. They occurred as follows:—Typhoid fever complicated with hæmorrhage and abscess, 2; Meningitis, 3; Sanguineous apoplexy, 1; Abscess of the brain, 1; Delirium tremens and diseased liver, 1; Cancer, 1; Phthisis, 5; Bright's disease, 2; Hypertrophy and valvular disease of the heart, 1; Obstruction and ulceration of the bowels, 1.

Brighton, January 1853.

ON THE MEDICO-LEGAL SIGNIFICATION OF CLOSURE OF THE FORAMEN OVALE.

By JOHN C. BLOXAM, Esq.

THE perusal of an article in the ASSOCIATION JOURNAL of the 4th current, by Dr. C. Kidd, on the Medico-legal Signification of Closure of the Foramen Ovale, induces me to offer a few remarks on the same subject.

The formation of the foramen ovale, and the mode of its closure, have often appeared to me to be misunderstood. The foramen is not formed like a hole punched out of a piece of paper, and is not, except as the consequence of disease, subject to have a layer of lymph thrown across it. The formation of the foramen resembles a slit cut through a piece of paper, which admits of being held in such a position as to form an oval-shaped opening; but it also admits of being held in such a position as effectually to close this aperture. In the new-born infant, the structures round the foramen are, also, so formed that the two lips of the opening admit readily of being made to overlap one another. Now, prior to inspiration, I apprehend that the parts remain in a position which preserves the patency of the foramen, but upon an effectual inspiration being made, the altered relative position of the different parts of the heart, (caused

partly by the distension of the right ventricle, through the expanding influence of the act of inspiration, whereby it becomes filled with blood), as well as the altered position of the whole organ, through the descent of the diaphragm, causes the opening to be, practically and functionally, completely and instantaneously obliterated, in consequence of the two lips of the opening being brought into the same plane. The lips, when thus brought into contact, and overlapping one another, gradually unite; but the opening is effectually closed without such union.

It is very easy for an observer to be deceived as to the patency of the foramen, especially when the examination is made with the heart *in situ*. The foramen may have the appearance of being completely obliterated, and yet, upon some accidental movement of the parts, the two lips may be made to slide upon one another, so as to leave a small opening between them; or they may be brought into different planes, and the opening thus be restored to its original dimensions. From my own observations, I have no doubt that the foramen may, in some cases at least, be restored to its original dimensions some considerable time after respiration has been thoroughly established.

Newport, Isle of Wight, February 1853.

ON MEDICAL METEOROLOGY.

By T. MOFFAT, M.D., F.R.A.S.

FOR some years I have kept a register of daily observations of the barometer and other meteorological instruments, the amount of atmospheric ozone, and the dates of the commencement of diseases, as they occurred; and from what I have observed, I readily concur with the opinion of Dr. Addison, as stated in his article on "Requirements in Meteorological Tables", that the changes of the weather are prejudicial to health, and that mean readings of meteorological instruments do not show the connexion between the prevalence of diseases and atmospheric conditions. I feel confident that meteorological tables cannot be of any value, in a medical sense, unless they are formed of daily observations, and include the date of commencement of individual diseases; for even a slight increase or decrease in the readings of the barometer, with a change in the direction of the wind, leads to an increase in the number of cases, or to their entire removal. I have observed that the following diseases,—viz., apoplexy, epilepsy, infantile convulsions, and sudden deaths, premature labour, menorrhagia, uterine pains, diarrhoea with sickness, and with or without cramps, toothache, neuralgia, etc.,—seldom occur without decrease of the readings of the barometer and changes of weather; that snow and hail showers are, all but invariably, accompanied by seizures of apoplexy, epilepsy, and sudden deaths; and that ozone never appears without a decrease in the readings of the barometer, and that its presence or absence in the air depends entirely on the direction of the wind.

Of the number of cases of apoplexy which occurred in the years 1850 and 1851, fifty per cent. took place on days of decreasing readings of the barometer, and fifty per cent. happened on days after such readings; one hundred per cent. occurred with fall of temperature, and they all took place with a direction of wind from the S.E. and S.W. points of the compass. Of the cases of epilepsy in the same years, sixty-nine per cent. occurred with decreasing readings of the barometer, and ninety-eight per cent. took place with decreasing readings of the thermometer. Of the cases of toothache, ninety per cent. commenced with fall of the barometer, and seventy per cent. with fall of temperature. Eighteen out of twenty-three cases of premature labour occurred with decreasing readings of the barometer, and either a reappearance or an increase in quantity of ozone. Of seven sudden deaths, five occurred with wind from N.W. with hail showers. All the diseases above enumerated observe a similar rate of per centage, to similar readings of the barometer and thermometer. Directions of the wind appear to influence the prevalence of certain diseases; for all

the cases of rheumatism which came under my notice in the same years, commenced with directions of the wind from southern, north-western, and intermediate points; as also did all the cases of bronchitis and pleurisy. All the cases of infantile convulsions commenced with the wind in the W. and N.W. points. All the cases of erysipelas took place with a wind from N. and S. and intermediate points, by way of W.; while toothache and neuralgia occurred with the wind from all points of the compass; but these two last diseases, diarrhoea, and some others, are *invariably followed by a decrease in the readings of the barometer, and a change in the direction of the wind.*

The following may be viewed as a type of a meteorological process, and of the class of diseases which accompany it. If the wind continue from the northern points of the compass, that is, from points between N.W. and S.E. by way of E., the barometer readings will remain high, there will be few or no cases of disease, and no ozone; but if the wind passes into southern points, that is, to points from N.W. to S.E. by way of W., the readings of the barometer will decrease, there will be toothache, neuralgia, and diarrhoea, etc.; there will be ozone, and general changes in the weather; and when any of these diseases occur, *when the wind is in the northern points*, they are a certain indication that decreasing readings of the barometer will follow in a few hours, and ozone will be detected, or not, just as the northern or southern current prevails.

These conclusions are the result of close and uninterrupted observations during four years.

Hawarden, Flintshire, February 5, 1852.

BIBLIOGRAPHICAL NOTICES.

PATHOLOGY AND TREATMENT OF HYSTERIA. By ROBERT BRUDENELL CARTER, Member of the Royal College of Surgeons of England. 8vo. pp. 161. London: 1853.

For a young author, Mr. CARTER's choice of a subject may appear to be a bold one. Hysteria, with its Protean manifestations, inscrutable mental and moral states, sexual sympathies, and admixture of real and imaginary, true and feigned complications, may well demand the study of a lifetime, and an experimental acquaintance with human nature and its infirmities, such as we expect to find only in those of mature years, and who have devoted themselves to much observant intercourse with mankind. But Mr. Carter enters with no ordinary advantages upon the task he has undertaken, and has succeeded in fulfilling it in a corresponding manner. He has, as he tells us in his preface, enjoyed the confidence, and assisted in the practice, of one who was extensively known by his successful treatment of the most inveterate hysterical disorders. To the memory of this gentleman,—the late Mr. Stephen Mackenzie, of Leytonstone, who was overtaken a short time ago in the midst of health and increasing reputation and usefulness, by sudden death from accident,—the book is appropriately dedicated; and we are given to understand, that on his opinions and precepts the views of the author have been formed. The book, at the same time, bears ample evidence of independent thought and study having been brought to bear upon the subject; and, in its style and arrangement, is highly creditable to the abilities and judgment of the author. We shall endeavour to give, in the shortest possible compass, an idea of its contents.

Mr. Carter altogether sets aside those theories of hysteria which seek for its origin in a physical cause, whether that cause be some unknown state of the general constitution, or irritation of particular organs, as of the uterine system. In his view, it is purely mental in its origin, and is to be considered a disease of emotion. By the term emotion, he explains himself to mean certain vivid feelings or sensations associated with an idea of pleasure or pain, and aroused by objects either perceived, or remembered, or

imagined, or by the remembrance of other prior emotions. After tracing the effects of emotion, in the state of health, upon the muscular, circulating, and secreting systems of the body, and pointing out the influence of attention directed towards any portion of the organism, in rendering it not only prone to gradual changes of nutrition, but also to become the habitual outlet for any strong emotion, the author proceeds to apply these facts to the subject of hysteria. Women are more liable to its attacks than men, because they are more under the influence of emotion, and because there are many powerful emotions—and those not alone confined to the sexual passion—which, in the state of society in which we live, they are called upon to repress and conceal. And it is laid down as an invariable rule, that the paroxysm will be violent, in exact proportion to the length of time during which the feelings giving rise to it have been concealed. Females are at the same time peculiarly exposed to circumstances, such as the periodical recurrence of menstruation, and the disturbances to which that function is liable, that tend to concentrate and fix the attention upon the reproductive system. Anæmia, chlorosis, and other conditions of impaired health, are not to be regarded as causes of hysteria; though, by weakening the body, they diminish the power of resisting emotional influences, and thus augment the proclivity to the disease.

The convulsive paroxysm is considered by the author to be the essential characteristic of the disease, and all the other manifold phenomena which are usually recognized as hysterical, to be merely secondary and non-essential. If the fits occur alone, or are accompanied with certain physical complications only, the case is called simple hysteria; if involving much moral and intellectual, as well as physical derangement, it is called complicated. But a more important classification of cases of the disease, according to the views of our author, is that which refers to the mode in which the emotions giving rise to the paroxysm have originated, whether they are original or remembered; and in the latter case, whether suggested involuntarily, or recalled at will. Each case will thus be brought under one or other of the heads of primary, secondary, or tertiary hysteria. The primary cases are those which are excited by some original and fresh emotion, to the action of which the system has not before been subjected. The attack may exhaust itself in one paroxysm, but it generally leaves its subject in a state of greatly increased susceptibility—so much so, that emotions not sufficient to produce a first attack may readily give rise to subsequent ones. In particular, whatever recalls to memory the original exciting cause, as conversations, the visits and sympathy of friends, or brooding over an all-engrossing subject of contemplation, is extremely apt to renew the paroxysm. Such attacks, following upon remembrance of the emotions to which the primary attacks were due, are termed secondary hysteria, and often constitute a severe and protracted form of disease. But if these remembered emotions happen to be of a pleasurable character, there are many temptations to a patient to endeavour to recal them spontaneously, and thus to induce paroxysms which render her an object of sympathy, interest, and indulgence—if not purposely, at least by a ready surrender of the counteracting power of the will. A certain amount of practice will not fail to increase the facility with which this can be done. And thus arises the third class of cases—those of tertiary hysteria, in which the paroxysms are designedly excited by the patient, through the instrumentality of voluntary recollection, and with perfect knowledge of her own power to produce them. This necessarily supposes a deterioration in the moral tone of the character, and an indulgence in habits of falsehood and deception, which, if not checked, may be carried to extraordinary lengths. It is to this tertiary form of the disease, that all cases of complicated hysteria are to be referred.

It naturally follows, from the views which we have laid before our readers, that the treatment of hysteria advocated by Mr. Carter is essentially of a moral nature. If there is any morbid condition or diathesis present which, by its

debilitating effect upon the system, may increase the proclivity to hysteria, such state will of course be treated by appropriate remedies. But he cautions us against supposing that these remedies, or any therapeutic agent whatever, can cure hysteria. On the contrary, therapeutic agents often do harm, and perpetuate the disease, especially when it has passed into the tertiary form.

"As soon as the deceptive element comes into play, the practical complicity of the medical attendant is sought as one of the patient's most secure strongholds, and frequently is quite essential to the success of her schemes. Hence arises that insatiable desire for remedies, with which all who have seen tertiary hysteria are familiar, and that excess of confidence in the practitioner, which is always exhibited until his suspicions are aroused. The professional man who has once sanctioned imposture, by sending medicines for the cure of self-produced illness, becomes at once an ally, whose aid is the more important because unconsciously rendered. And moreover, when to the voluntary production of convulsive attacks is added the simulation of disease in some individual organ, the frequent application of medicines for the relief of the local affection, and the medical belief in its reality, which such applications imply, is likely to hasten the arrival of that last epoch in the history of simulative hysteria, when the continued attention from the malingerer brings its own retribution, and actually produces the morbid condition which she has feigned."

The treatment of the primary and secondary forms of hysteria is very briefly discussed, to make room for that which, with the views of the author as to its nature and phenomena, forms a principal portion of the book—namely, the cure, by moral management and control, of cases of the tertiary form. Space will not permit of our giving an analysis of the author's plan of treatment. Suffice it to say, that it proceeds upon the principle of taking away from the patient all motives for deception, or the voluntary production of convulsive attacks, by satisfying her that the full extent of her deception is seen through by her medical attendant, and may be exposed to her humiliation and shame, if she do not abandon it. Of course this cannot be fully carried out without her removal for a time from all the influences and indulgences of home, and the interference of well meaning, but injudicious friends. Nor is it enough merely to eradicate bad habits and principles—good ones must be formed and instilled in their place, before she can be restored to her friends and society as cured. The task is one in which, as the author justly observes, "however much the practitioner may possess of firmness, coolness, and tact—however much knowledge of human nature generally, and of the character of the individual under his charge—none of these powers or acquirements will be found either redundant or superfluous." It is not every one, indeed, who is in a position to carry out the instructions given in Mr. Carter's book, for the treatment of this aggravated form of hysteria; but to all they will furnish useful hints for the regulation of their intercourse with its unfortunate victims, and for the bringing moral influences to bear upon them.

TREATISE ON AUSCULTATION AND PERCUSSION. By Dr. JOSEPH SKODA. Translated from the fourth edition, by W. O. MARKHAM, M.D., Assistant-Physician to St. Mary's Hospital. 8vo. pp. 346. London: 1853.

THE profession is indebted to Dr. MARKHAM for presenting to them, in an English dress, the classical work of Dr. SKODA. The version is accurate and elegant; and it is accompanied by a sensible and well-written preface from the pen of the translator, who, along with the author, rightly considers that it is a prevalent mistake to trust too exclusively in our diagnosis to auscultation and percussion. The peculiar views of Skoda have of late years been so largely explained and criticised in English works, that we will not, upon the present occasion, enter upon their discussion, but content ourselves by recommending Dr. Markham's volume as the best source whence to derive a knowledge of these important doctrines.

MEMOIRES DE LA SOCIÉTÉ DE CHIRURGIE DE PARIS. Tome Troisième. Fascicules 2me et 3me. 4to. pp. 255. Paris: September 1852, and January 1853.

WE have received two fasciculi of the Transactions of the Surgical Society of Paris, with a proposition of exchange, which we most willingly accept. On the present occasion, we can do nothing more than indicate the titles of the essays contained in the Transactions; but we intend to notice some of them more in detail in our Periscopic Review.

1. On the Communication of Certain Ovarian Cysts with the Fallopian Tube. By Dr. Adolphe Richard. 2. Tracheotomy in Croup: Case of a Child twice attacked with Croup in Two Years, and twice operated on successfully. By M. P. Guersant. 3. Researches on Lymphorrhagia and Dilatation of the Lymphatic Vessels. By M. Demarquay. 4. On some Surgical Diseases of the Insane. By Dr. Deguise. 5. On Concussion of the Brain. By Dr. S. Fano. 6. Report on Dr. Fano's Memoir. By M. Chaiassaignac. 7. New Improvements in the Treatment of Vesico-Vaginal Fistulæ. By M. Maisonneuve. 8. On Cysts of the Maxillary Bones, and their Treatment. By M. A. Forget. 9. On Neuroma, with a Case of numerous Neuromata. By M. Houel. 10. Report on M. Houel's Memoir. By M. Lebert. 11. Case of very large Scrotal Hernia, with Gangrenous Ulceration of the Bladder, Urinous Infiltration of the Sub-Peritoneal Cellular Tissue simulating Hernia of the Bladder. By Dr. Pytha. 12. Some Remarks on Localised Traumatic Paralysis. By M. Debout. 13. New Cases of Rupture of Angular Anchylosis of the Knee, according to the Method of M. Palasciano. By M. Bonnet (of Lyons). 14. Chronic Hydrarthrosis; Pedunculated Sub-Synovial Abscesses simulating Fibrous Bodies in the Knee; Synovial Cysts, etc. By Dr. Verneuil.

French surgeons, from Ambroise Paré downwards, have done much for the advancement of our profession; and although some of them occasionally promulgate doctrines, or propose operations, such as we should be reluctant to adopt, we must feel ourselves under deep obligations to them. The Transactions of the Surgical Society of Paris contain much that is valuable. The authors of several of the articles deservedly enjoy an extensive and honourable reputation, as promoters of improvement in surgical pathology and practice; and the essays are no less creditable to the French school of surgery than to those whose names are appended to them.

PERISCOPIC REVIEW.

TOXICOLOGY.

DEATH FROM THE INHALATION OF CHLOROFORM DURING SURGICAL OPERATIONS.

Among the now innumerable cases in which chloroform has been administered with the object of procuring insensibility to pain during surgical operations, about twenty-five cases have been recorded, in which death was the immediate result of its inhalation. We cannot suppose that all the deaths which have occurred have been made public; yet, even allowing the number to be doubled, the small proportion which they must bear to the total number of cases, shows that they supply no argument against the judicious use of chloroform; at the same time, they teach us the advisability of using at least moderate precautions when we employ so potent an agent.

We propose to exhibit the cases in a tabular form; and in so doing, we shall avail ourselves of the elaborate paper published by Dr. SNOW, in the *London Journal of Medicine* for April, May, and June, 1852, adding such cases as we have met with in other journals since that date. We may also refer to Mr. NUNNELEY's numerous experiments and observations, published in the *Transactions of the Provincial Medical and Surgical Association* for 1849.

TABULAR VIEW OF RECORDED CASES OF DEATH FROM CHLOROFORM.

No.	Date.	Name.	Age.	Operation.	Apparatus.	Quantity used.	Time when death occurred.	Symptoms.	Post mortem appearances.	Reference.
1	Jan. 28, 1848.	H. Greener.	15	Toe-nail operation.	Table-cloth.	One drachm.	Two minutes.	Rigidity of muscles; pulse weaker; eyes closed, but on opening them they remained so; mouth open; lips and face blanched.	Lungs congested; epiglottis and larynx reddened; heart healthy, dark fluid blood in both cavities; very little in left. Brain rather congested. Liver, kidneys, and spleen, congested.	Lancet, 1848, vol. i, p. 161.
2	Feb. 23, 1848.	Mrs. Simmons	—	Extraction of teeth.	Apparatus of Dr. Morton of Boston (sponge partly filling a glass globe).	—	Two minutes?	Pallor while inhaling; convulsive action in limbs and body; pulse and respiration ceased at two minutes.	Lungs and bronchi congested; congestion of pleura, and extravasation. Heart flaccid, empty, deeply stained; bloody fluid (3vj) in pericardium. Brain normal. Blood quite fluid everywhere; mixed with some air in sinuses of dura mater.	Medical Gazette, vol. xli, p. 277.
3	Mar. 1848.	Patrick Coyle.	—	Operation for fistula in ano.	—	Thirty drops.	One minute.	Signs of pain, by putting hand to part; sinking of pulse. Was suffering from phthisis.	Lungs tuberculous; pleura adherent. Heart enlarged, pale, and soft; 3ij-ij of serum in pericardium; blood dark and fluid in vessels. Brain healthy.	Ibid., vol. xliii, p. 682.
4	—	Young woman.	—	Amputation of distal phalanx of finger.	Handkerchief.	A drachm.	Instantly.	Slight coughing; a few convulsive movements; instantaneous death; scarcely any bleeding from wound.	No inspection.	Ibid., vol. xlii, p. 84.
5	May, 1848.	Mdlle. Stock.	30	Opening an abscess.	Handkerchief.	A drachm and a half or two drachms.	Almost instantly.	Complained of choking; face pale; countenance changed; breathing embarrassed; foaming at mouth.	Lungs engorged in lower lobes; pulmonary vesicles dilated by artificial respiration. Heart flaccid, of usual size, empty. Brain firm. Blood thick. Air in veins generally, and in pulmonary artery.	Ibid., vol. xlii, p. 211.
6	1848.	C. Desnoyers.	22	Transcurrent cauterisation of diseased wrist.	Apparatus.	Not stated.	Five minutes.	Not stated.	No account of inspection.	London Journal of Med., May, 1852, p. 417.
7	Dec. 7, 1848.	Young gentleman.	—	Intended toe-nail operation.	Not stated.	Not stated.	Almost instantly.	Not stated.	No account of inspection.	Ibid., p. 418.
8	Jan. 19, 1849.	John Griffith.	31	Removal of hemorrhoids.	Napkin.	Three drachms.	Ten minutes.	Face and neck of livid leaden hue; eyes turned upwards; pulse imperceptible at wrist; whole body relaxed.	Lungs congested. Heart large, flabby, and empty; left ventricle rather soft. Brain healthy.	Ibid., vol. xliii, p. 712.
9	Jan. 24, 1849.	J. Verrier.	17	Intended amputation of finger.	Piece of gauze spread over face.	About a drachm and a half.	Six minutes.	Pulse at wrist ceased; respiration continued for a time, ceasing gradually.	Lungs very black. Heart flaccid and empty. Brain healthy; much black uncoagulated blood in sinuses. Blood fluid.	Ibid., vol. xliii, p. 745.
10	Feb. 20, 1849.	S. Bennett.	—	Amputation of toe.	Handkerchief.	Half an ounce.	—	No bleeding at end of operation. Inspiration noticed after pulse had ceased.	Lungs, trachea, and bronchi, congested. Heart rather large, flabby, auricles empty. 3j of fluid blood in each ventricle. Nothing remarkable in head. Kidneys congested.	Lancet, 1849, vol. i, p. 205.
11	Aug. 23, 1849.	Madame Labruno.	—	Intended extraction of teeth.	Handkerchief.	—	Instantly on applying 2nd supply to complete	Countenance suddenly pallid; features altered; pupils dilated; convulsive rolling of eyes; failure of pulse.	No inspection.	L'Union Médicale, Sep. 8, 1849.

No.	Date.	Name.	Age.	Operation.	Apparatus.	Quantity used.	Time when death occurred.	Symptoms.	Post mortem appearances.	Reference.
12	Oct. 10, 1853.	J. Shorter.	48	Toe-nail operation.	Inhaler (used by a non-medical person.)	Not stated.	—	Struggled a minute, then became still; skin cold; pulse soon ceased; respiration became slow, and ceased, having continued after the cessation of the pulse.	No inspection.	Medical Gazette, vol. xlv, p. 757.
13	Nov. 1849.	— Jones.	A girl.	Intended removal of eye-ball.	—	About a drachm.	Instantly.	Not described.	No inspection.	<i>Ibid.</i> , p. 1007.
14	Nov. 1849.	Young lady.	—	Intended extraction of tooth.	Sponge, covered with a napkin.	Several doses.	Suddenly at commencement of sixth attempt.	Stretched herself out, and foamed at mouth; died suddenly.	Lungs healthy. Heart soft and flabby, empty. Blood fluid. Brain normal; membranes slightly congested.	Medical Times, vol. ii, p. 230.
15	Feb. 1850.	Artillery-man.	—	Amputation of phalanx of finger.	Handkerchief.	A drachm.	—	Face pale; pulse and breathing ceased.	Lungs emphysematous. Right cavities of heart contained fluid blood. Less blood than usual in sinuses of dura mater and in brain.	London Journal of Med., 1852, p. 420.
16	June, 1850.	A. Scott.	34	Removal of portion of hand.	Napkin.	—	A minute and a half.	Bleeding suddenly ceased.	Lungs, brain, dura mater, and kidneys, much congested. Heart feeble and flabby; not much blood in it.	Medical Gazette, vol. xvi, p. 80.
17	Sep. 20, 1850.	James Jones.	24	Intended amputation below knee.	Lint, sponge, and towel.	A drachm and afterwards half a drachm.	—	Slight convulsive action of left eyelid; froth at mouth.	No inspection.	
18	April, 1851.	John Holden.	—	Intended operation on penis.	Handkerchief.	Half a drachm: ditto repeated.	Suddenly.	Not stated.	No inspection.	
19	June 10, 1851.	Madame Simon.	36	Extraction of teeth.	Handkerchief.	About 50 minims.	Less than a minute.		Lungs somewhat congested, and emphysematous. Heart flaccid, of moderate size. Dark fluid blood, with some fibrinous clots, in both cavities; most in right. Chloroform found in organs by chemical process.	L'Union Médicale, 29th Jan. 1852.
20	July 8, 1851.	Thomas Hutton.	45	Extirpation of testis.	Handkerchief.	Seventy minims, in four doses.	Soon after operation was commenced.	Flow of blood, and pulse ceased; one or two deep inspirations after.	Lungs, dura mater, and kidneys, congested. Heart flabby and soft; contained but little dark fluid blood.	Medical Times, 1851, vol. ii, p. 98.
21	Oct. 1851.	Elizbth. Hollis.	37	Intended operation for cancer of os uteri.	Handkerchief.	Eight or ten drachms.	Uncertain.	Not stated.	No inspection.	<i>Ibid.</i> , 1852, vol. ii, p. 620.
22	June, 1852.	Young man.	23	Ligature of arteries for aneurism by anastomosis.	Apparatus.	—	About ten minutes.	Sudden cessation of pulse; respiration continued; red colour returned to face.	Lungs healthy, but collapsed. Right cavities of heart contained fluid blood; left very little. Blood everywhere fluid.	Medical Times and Gazette, 1852, p. 310.
23	May 22, 1850.	Man in Stockholm.	30	Intended operation for hydrocele and diseased testicle.	Cotton placed in cone formed of folded towel.	A drachm and a half: then a drachm.	About five minutes.	Face and body pale; eyes rolled upwards and inwards; breathing became slow, and ceased.	Brain rather soft, slightly œdematous. Heart flaccid, of normal size; vessels on surface distended; left cavities empty, right, and great veins, filled; lungs posteriorly, larynx, and bronchi, congested. Blood everywhere thin & fluid.	London Journal of Med., 1852, pp. 423 and 695.
24	June 27, 1851.	Madame W.	32	Intended extraction of tooth.	Sponge in a handkerchief.	Twenty-five drops.	Very soon.	Speech trembling; stretched out limbs; face livid; eyes haggard; head and arms fell.	Heart soft, flaccid. Organs much congested with fluid blood, containing air.	Gazette Médicale, Oct. 2, 1852.
25	Aug. 10, 1852.	Mr. Martin.	—	Application of potassa fusa to ulcers in leg.	Not stated.	Not stated.	A few months.	Mouth and eyes open, breathing irregular, face pale, eyes turned slightly upwards, pupils dilated.	No examination.	Monthly Journal, Oct. 1852.

Several points suggest themselves for consideration, principally with regard to the cause of death.

1. Dr. Snow lays much stress on the necessity of sufficiently diluting the chloroform; and, as is well known, is much opposed to the plan of using a handkerchief or napkin, which appears to have been the only apparatus used in most of the fatal cases. In the *London Journal of Medicine*, April 1852, p. 323, he says: "There is no reason to believe that any of the accidents from chloroform have arisen from the continued exhibition of the vapour well diluted with air. On the contrary, the sudden manner in which the alarming symptoms came on in every case, shows that they were produced by the respiration of air containing not less than eight or ten per cent. of the vapour; and, from the history of the cases, it is most probable that the heart was disabled, in most instances, by the direct action of the chloroform. No systematic means were taken for properly diluting the vapour with air, in any case in which death has happened. The chloroform was exhibited on a handkerchief, or towel, or piece of lint, in all the cases but three; and, in two of these, it was not applied by a medical man. In order to show how easily accidents may happen with chloroform, I must beg attention to a few circumstances connected with its physical as well as physiological properties. On a former occasion, I showed (*Medical Gazette*, vol. xliii, p. 414), both from experiments on animals, and the amount of chloroform consumed in inhalation, that the average quantity of it in the blood of an adult patient, when insensible to the surgeon's knife, is about eighteen minims, and that, if twice that amount were present in the blood, it would suffice to cause death, even if it were uniformly distributed. Now thirty-six minims of chloroform, when in the form of vapour, only occupy thirty-seven and a half cubic inches, or very little more than a pint. It is true, that the vapour of chloroform does not exist in a separate state at the ordinary temperature and pressure of the atmosphere; but air, when saturated at 60°, contains rather more than twelve per cent. of the vapour; and, supposing the air to contain ten per cent., which it does when the chloroform dew point is at 55°, the thirty-six minims would be contained in 375 cubic inches of air, more than half of which might possibly be in the lungs at one time." To prevent this result, he recommends and uses a special apparatus fitted with valves; and would also have the chloroform diluted with an equal part of rectified spirit, when—as must often occur when an inhaler cannot be conveniently procured—a handkerchief or sponge must be used. The effects of chloroform, administered in this way, are slower in being produced; but then the chance of a fatal result is much diminished. This is a valuable suggestion; and an equally important point to be attended to, in our opinion, is that, during operations, it should be the special business of a competent person to watch carefully the effects of the chloroform on the patient from the commencement of inhalation. Of course, no medical man—and no one else should attempt to give chloroform—would think of at once closing up the nostrils and mouth of the patient with a saturated handkerchief, sponge, or lint, to the exclusion of atmospheric air.

2. The symptoms and *post mortem* appearances recorded, point to arrest of the heart's action as the cause of death; and in the majority of the autopsies, this organ is mentioned as having been soft and flabby. Yet, according to Dr. Snow, it has not in any case been extensively diseased: while he has "several times given chloroform during surgical operations, when very marked disease of the organ existed, and to a great number of old people, in whom the arcus senilis in the cornea might lead to suspicion of its being affected with fatty degeneration." While then, heart-disease is scarcely a contra-indication to the use of chloroform, it should make us exceedingly careful to administer it slowly, and to watch its effects; and with these precautions, we may adopt Dr. Snow's view, that it will then be even beneficial. "The action of chloroform on the circulation, when sufficiently diluted with air, is that of a stimulant. It has a very marked effect in preventing syncope during surgical operations; and, as syncope is attended with danger in diseases of the heart, there is reason to believe that the careful administration of chloroform is a means of safety to patients who, notwithstanding the heart-disease, have to undergo an operation. Moreover, the pain of even a slight operation has generally the effect of accelerating the pulse to about twice its natural frequency; and it is well known that mental excitement, muscular exertion, or any other cause which has such an influence on the circulation, may occasion sudden death where there is disease of the heart; but, as the pulse usually remains of its natural frequency and force during an operation under the effects of chloroform, this circumstance further confirms the

conclusion, that the careful use of this agent is a source of safety, and not of danger, to the patient with heart-disease. In these patients, however, I think it desirable to conduct the inhalation in such a manner that excitement and struggling may be avoided, and not to prolong the use of chloroform longer than is absolutely necessary, for protracted insensibility is sometimes followed by depression. I am happy to be able to quote the opinion of Dr. Sibson, who has paid great attention to the subject of chloroform, in favour of its employment under certain circumstances where there is disease of the heart. He says: 'persons, the subjects of heart disease, when the dread of a severe operation is great, may sometimes be peculiarly benefited by the careful and short production of anæsthesia during the cutting part of an operation.' *Medical Gazette*, vol. xlii, p. 111.

Is the action of chloroform on the heart local, or does the paralysis of this organ take place through the influence of chloroform on the excito-motor system? This is a question open to investigation.

3. With regard to the treatment in cases where chloroform appears to be inducing a fatal effect, we know but little. Mr. Nunneley suggests sudden dashing of cold water on the face and chest, or producing a moderate stream of air by means of a fan,—moderate interrupted pressure on the chest and abdomen being at the same time employed. Dr. Snow places great reliance on the performance of artificial respiration, which, he believes, "would restore the patient in most instances, if it were put in force within half a minute after the breathing had ceased." He also advises that blood should be taken from the jugular vein, if the patient does not very quickly begin to show signs of returning animation.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

COMPARATIVE VALUE OF ANTHELMINTICS.

The subjoined paper is reprinted from the *Dublin Quarterly Journal of Medical Science* for February.

Dr. KÜCHENMEISTER has examined the various vermifuges, by immersing the living intestinal worms of fowls, cats, and dogs, in albumen, at a temperature exceeding 77° Fahr., and adding the anthelmintics in the form of infusion or of powder. In some cases, a mixture of warm milk and water was substituted for the albumen. The experiments were not continued for more than from forty to forty-eight hours, if the worm had not been killed before the expiration of that time. Dr. Küchenmeister made use of electricity as the most delicate reagent for proving the occurrence of the death of the worms. In the first place, electricity cannot be considered as a vermifuge. The author subjected a female *Heterakis vesicularis*, taken from a partridge that had been killed, to the action of a rotatory apparatus, which was kept up with longer or shorter intervals during an entire day. The animal was not destroyed by the experiment. He next tried the remedies employed for the removal of tæniæ, and first tested kousso in the following manner. A living *Tænia crassicolis*, procured from a cat, was placed at four o'clock in a mixture of albumen and dolichos pruriens. The worm appeared to be perfectly well in this mixture, and at two o'clock on the following afternoon exhibited most vigorous movements. It was now transferred to a vessel containing a mixture of infusion of kousso and some of the infused as well as of the fresh powder, with albumen. The temperature of the mixture was 99°·5° F. On its introduction, the worm quickly extended itself; after some time it was found to be dead, its colour having changed to a dirty reddish-yellow. Two *Tænia serrata* were placed at half-past one in the afternoon in a mixture of albumen and kousso; at two o'clock they were dying, and at three completely dead. Two *Tænia serrata* from the same dog were brought into contact with kousso and milk at half-past one in the afternoon, and at two o'clock were dead. Two *Tænia serrata* were placed at half-past one in the afternoon in albumen, mixed with decoction of pomegranate root and with some of the powdered root: they died in three hours. Two others were placed in milk mixed with the decoction only: they died in three and a half hours. A *Tænia crassicolis* was put into a mixture of albumen with ethereal extract of male fern: it died gradually in three hours and three quarters. A number of *Tænia cucumerina* were placed in a mixture of albumen and oil of turpentine: they were dead in an hour and a quarter.

A number of the same were put into a mixture of albumen and castor oil; they were lively at first, but died in seven hours. Similar worms were put into a salad, composed of pieces of lettuce.

watered herring, boiled potatoes, large pieces of onion and garlic, albumen, vinegar, and a large quantity of oil. They died in eight hours. Lastly, the author tested the vermifuge powers of the brown oxide of copper: fifteen grains were administered in the course of four days to a strong cat. When the body was opened, the entire intestinal canal was found to be full of fluid, yellow, flaky faeces; the intestine was softened, and denuded of epithelium, especially at the termination of the ileum, where the adjoining Peyer's glands were much swollen, particularly in two situations, one of which was an inch and a half long by one-third of an inch broad; the other was nearly circular, and its diameter one-third of an inch. The cat had been purged. The tæniæ and ascarides it contained were lively. It would hence appear that this substance is inefficacious as a vermifuge, and dangerous to the system.

The following table contains the results of the above experiments:—

In milk boiled with koussou tæniæ died in half an hour.	
In a mixture of oil of turpentine and albumen, in 1 to 1½ hour.	
In decoction of koussou with albumen	1½ " 3 hours.
In decoction of pomegranate root with milk ..	3 " 3½ "
In decoction of pomegranate root with albumen	3 " "
In ethereal extract of male fern with albumen	3½ " 4 "
In castor-oil with albumen	8 " "
In salmagundi with garlic and onions	8 " "

Koussou therefore seems the most efficacious remedy against tæniæ. When pomegranate bark and male fern root fail, their failure may be owing to the habit of administering a laxative in from four to six hours after the exhibition of the vermifuge, by which the latter may be carried beyond the worm. With regard to pomegranate root, it must be observed that in large doses it occasions diarrhoea. The same remark applies to castor-oil. The author also alludes to cold water, strawberries, dolichos pruriens, and filings of tin. When tæniæ are placed in water containing ice, they are instantly benumbed, and if allowed to remain in it, they will always be found at the end of ten hours to be quite dead. Strawberries may be useful as a mild remedy in cases of tapeworm; if large quantities of them be taken on an empty stomach, entire portions of the worm will often be passed. Dolichos pruriens, with which the author tried many experiments, appears to possess no power of destroying worms.

The author has also minutely studied the medicines recommended for the removal of round worms. In albumen, these worms behave as the tæniæ; in water at about 77° F., they live for some days, but swell, stiffen, become longer, thicker, and more sluggish; they lose their power of suction, and their motions become slow and only partial,—they resemble leeches which have gorged themselves. In general, however, the males and young neutrals resist the effects of water longer than the mature, impregnated, egg-bearing females, which become quite rigid and inflexible, and swell considerably. Milk and whey affect the worms like water.

The following are the results of the author's experiments:—
1. An ascaris lived from eighteen to twenty hours in albumen into which some camphor had been introduced. 2. A mixture of oil of turpentine and albumen killed some ascarides which were placed in it from two and a half to six hours. 3. Ascarides lived forty hours in albumen and wormseed, whether the latter was employed in the form of powder or infusion. 4. Some ascarides were placed in albumen mixed with santonine; they did not die in it, nor did they die in a watery infusion of santonine. When santonine was dissolved in oil, especially in castor-oil, and mixed with albumen and ascarides, the latter died in ten minutes. An injection of santonine and castor-oil was thrown up the rectum of a cat, and produced numerous motions containing dead worms; and on killing the cat, the entire of the lower portion of the intestinal canal was ascertained to be free from worms, while four were found near the stomach quite rigid and extended, and retaining but little life. A *Tænia crassicolis*, however, was found in the intestines, and appeared to be quite uninjured and very lively. 5. A mixture of albumen and aniseed, with a strong infusion of the latter, killed the worms in about twenty-four hours. 6. Parsley, mixed with albumen, killed ascarides very slowly. 7. Flour of mustard and albumen destroyed them in about four hours. 8. In rue the worms lived upwards of twenty-four hours. 9. The same was the case with millefoil. In contact with tansy, valerian, and camomile, great numbers of them lived for twenty-four hours. With onions and garlic they perished in from ten to fifteen hours. A decoction of cloves, with or without albumen, killed them in twelve hours. In an infusion of ginger, with or without albumen, they lived about twenty-four hours. Petroleum,

mixed with albumen, killed them in less than six hours, as did also oil of cajeput and albumen.

A series of vermifuges, taken from the class of balsamics, namely, assafœtida, ammoniacum, balsam of Peru, extract of juniper, and Venice turpentine, was tried in like manner. In all these the worms lived more than twenty-four hours. Of the class of empyreumatics, the following were tried:—Oleum Chaberti (a mixture of four parts of oil of turpentine, and one of the animal oil of Dippel), oil of amber, castor-oil, tar water, creasote, wood-vinegar, and wood-soot. In these, for the most part, the worms lived from twenty-four to forty-eight hours; except the wood-vinegar, in which they lived rather more than twelve; and creasote, in which they died within two hours. Of bitters, the author tried aloes, gamboge, ox-gall, wormwood, myrrh, gentian, quassia, hops, bitter orange, and acorus calamus; in all these the ascarides lived from twenty-four to forty hours. Of astringents he tried pure tannic acid, pomegranate root, koussou, extract of walnuts, cinchona bark and quina, elm bark, willow bark, the flowers and stalks of meadow sweet, oak bark, dragon's blood, catechu, and kino. In these the worms died in from twenty-four to thirty hours, with but two exceptions, namely, tincture of galls and pomegranate root, both of which killed them in the space of eleven hours. Of saline preparations, sulphate of soda, chloride of sodium, and the roe of the herring, were tried. In the first, the worms died in from fifteen to eighteen hours; in the second, in from two to six; and in the roe of the herring, in four hours. The following metallic poisons were experimented on: arsenic, calomel, corrosive sublimate, and the salts of tin, of lead, and of copper. Corrosive sublimate alone destroyed the worms in so short a time as two hours; all the other metallic salts required a much longer period. From these experiments it would appear that santonine mixed with oil is the most powerful vermifuge, then chloride of sodium, the roe of the herring, garlic, onions, etc. The author advises that santonine should be given as a vermifuge, mixed with oil, in the proportion of from two to five grains, to an ounce of castor-oil. This solution should be given in the doses of a teaspoonful until the effect is produced. As auxiliary treatment, chloride of sodium, herring-brine, mustard, onions, and garlic, may be employed.—*Froriep's Tagsberichte über die Fortschritte der Natur- und Heilkunde*. Pharmakologie, Band 1, p. 317.

COMPOUND EXTRACT OF COLOCYNTH AND COMPOUND COLOCYNTH PILL.

At a recent meeting of the Pharmaceutical Society, reported in the *Pharmaceutical Journal* for December 1, 1852, Mr. ALFRED ALLCHIN stated, that he had found the compound colocynth pill of the new London Pharmacopœia to differ most materially in its medicinal effects from the compound extract of colocynth of the Pharmacopœia of 1836, being often much more powerful.

Dr. GARROD undertook to test the medicinal effects of the two preparations; and his results, which seem to satisfactorily set the question at rest, are published in the *Pharmaceutical Journal* for January 1, 1853. Most of his experiments were made on patients in the wards of University College Hospital. The compound colocynth pill (1851) was given in twenty-two cases; the compound extract (1836) was administered in fifteen cases. The patient thought the compound pill stronger than the compound extract in one trial; the compound extract was stronger than the pill in five; while, in the remaining trials, the patients could not distinguish any difference between the two preparations. The pill was accompanied by griping (noticed and spoken of by the patient) in six trials; the extract was accompanied by griping in four trials.

From these results, Dr. Garrod thinks that "we are fully justified in concluding that the compound colocynth pill of the London Pharmacopœia (1851) certainly does not possess more purgative action than the compound extract (1836). The result is slightly in favour of the latter preparation being the more powerful; but certainly no difference of power of the slightest practical importance to the physician can be detected."

Before the publication of the Pharmacopœia in 1851, there had been in common use a compound colocynth pill, the formula for which existed in the Edinburgh and Dublin Pharmacopœias. It was, we believe, of about the same strength as the compound extract of colocynth. We subjoin the formulæ for the three preparations.

Compound extract of colocynth. (Ph. Lond. 1836). Colocynth pulp, ℥vj; purified extract of aloes, ℥xij; powdered scammony, ℥iv; powdered cardamom seeds, ℥i; soap, ℥iij; proof spirit, cong. i.

Macerate the colocynth in the spirit for four days with a gentle heat; add the aloes, scammony, and soap, to the expressed liquor; then evaporate to a proper consistence, the cardamoms being added towards the end.

Compound colocynth pill. (Ph. Lond. 1851). Extract of colocynth, 3i; extract of aloes, powdered, 3vj; scammony, powdered, 3ij; cardamom (husked), powdered, 3ss; soft soap, 3iss.

Mix the powders together; then, the rest being added, beat all together to form a mass.

Compound colocynth pill. (Ph. Edin. et Dubl.) Aloes and scammony, of each, 3i; colocynth pulp, 3ss; Castile soap, 3ij; sulphate of potash, 3i; oil of cloves, 3i.

These are made into a mass: the Edinburgh Pharmacopœia directs rectified spirit to be used instead of soap.

EDITOR'S LETTER BOX.

THE RECENT INQUEST IN THE CASE OF ACCIDENTAL POISONING, AT THE CONVENT OF THE GOOD SHEPHERD.

LETTER FROM FRANCIS GRIGG, Esq., ONE OF THE JURY.

SIR,—My attention has been drawn to a letter in your Journal of the 28th ult., by Dr. O'BRYEN, relative to a recent inquest in a case of accidental poisoning by aconite, at the Convent of the Good Shepherd, in the parish of Brislington, county of Somerset.

Dr. O'Bryen states, that the conduct of the coroner and jury (of which I was a member) was so unusual, as to claim attention from the profession. He says also, that when the coroner and jury met at the convent to view the body, the coroner informed him that the jury could not allow him to be present, as they desired to make remarks, which they did not wish him to hear: that one of the jury insisted on taking the case out of his hands, and on nominating another surgeon to make the *post mortem* examination, without any reference to him: also, that he was ordered to leave the court during the whole time the witnesses were examined, without reason assigned, against which he protested, but in vain. He goes on to state:—"The effect" (I suppose he means the cause) "of the jury taking the place of the medical witnesses, in examining the body for themselves, was, that two spots of commencing decomposition on the abdomen were taken by them for marks of violence, and insisted on, even against my positive evidence, to the contrary; and they apparently yielded, when Mr. Prichard demonstrated the absence of violence in the tissues, and otherwise corroborated his statement. I say, apparently, for Miss Ryder was recalled, and sworn to the fact, that no violence had been used to the deceased." Lastly, he writes:—"What shall I say of the exclusion of the medical witnesses from the court? A hitherto unheard of proceeding! I was thus prevented from hearing and judging of the facts of the case, which might come out in evidence, and which in most cases would materially assist in deducing just conclusions. I had, however, taken care to examine all the witnesses myself, and had quite made up my mind that Emma Forty had died from the effects of about seventy drops of 'Fleming's tincture of aconite,' given by mistake."

In reply to Dr. O'Bryen's first charge, "of unusual conduct in the coroner and jury, in that they would not allow him to be present when they viewed the body", I beg to say that, although on such an occasion the coroner and jury can exclude any person, yet they would not have done so in this case, if Dr. O'Bryen's manner had been less officious, and his interference not such as to delay or interrupt the proceedings, by wishing to instruct the coroner and jury as to their duty. I beg also to say, that there is nothing unusual in a coroner and jury requesting that another medical man, who had not been previously connected with the case, should conduct the *post mortem* examination. I do not see why Dr. O'Bryen should feel aggrieved at his being requested (not ordered) to leave the court, as each witness would be called and examined separately. Such a proceeding, I believe, so far from being unusual on such an occasion, is one which is generally adopted in courts of justice.

The jury, I am sure, will be considered by the profession, and the public generally, only to have done their duty in desiring an examination of the body, when, in their opinion (at the time of viewing the body), there appeared two marks, re-

sembling bruises (one of them very large), on either side of the abdomen; especially when coupled with the fact, that persons, at different times, in passing along the high-road late at night, had heard cries, or screams, proceeding from the convent. The jury were afterwards perfectly satisfied, from the evidence of Mr. Prichard, that the marks on the body were merely the result of decomposition. Miss Ryder's having been recalled was for the jury to understand from her, whether she was quite certain that she gave the dose to the deceased from the bottle containing the aconite. She replied in the affirmative; and then the jury felt no longer any hesitation in giving their verdict. I mention this, as, on the Thursday previous, Miss Ryder, from distress of mind, seemed rather confused in giving her evidence. Miss R. was also asked if the deceased were treated unkindly; she replied, No; that the deceased, Emma Forty, was beloved by all the inmates, in consequence of her amiable disposition. I repeat again, in reply to Dr. O'Bryen's inquiry as to what he should say regarding the exclusion of the medical witness from the court, styling it "a hitherto unheard of proceeding",—that such a proceeding is usual in courts of justice; and why should it have been otherwise in an inquiry into the almost sudden death of an inmate of such an establishment as the Convent of the Good Shepherd?

I feel sorry that Dr. O'Bryen should be possessed of so bad a memory as to make a statement of the symptoms of the deceased, subsequent to her taking the poison, so widely different to that which appears in the *Mirror* and the other Bristol papers of the 15th and 22nd January last, from the evidence deduced, and there correctly shown; to which I would most particularly call your attention. There were four reporters present, and I consider their concurrent statements as worthy of credence.

FRANCIS GRIGG, one of the Jury.

Hengrove House, Brislington,
near Bristol, February 2, 1858.

[In some courts, medical witnesses are not allowed to hear the testimony of the other witnesses; but the practice has not been sanctioned by any medical jurist of eminence. In the present case, Dr. O'Bryen ought either to have been present at the examination of the body, or his exclusion ought to have been distinctly stated to be essential for the reasons assigned by Mr. Grigg. We thoroughly believe that the coroner and the jury acted according to their view of what was right; but still we think that the exclusion of Dr. O'Bryen requires a much stronger and more circumstantial vindication than Mr. Grigg has supplied. The point, however, is too narrow for further discussion in our pages, where we cannot allow important principles to be lost sight of, by our discussing the mere personalities which are attached to them.—EDITOR.]

ABUSE OF THE CHELTENHAM GENERAL HOSPITAL.

SIR,—I had just finished reading your excellent articles in the Journal for January 28th, on "The Abuse of Hospitals and Dispensaries", and on "The Shabby Tricks of the Guardians of the Ledbury Union", when the *Cheltenham Journal* of this week was put into my hands, containing a specimen of the *pleasing* results which medical men may expect from their attempts at "memorialising the various committees and boards of governors to stop the present wholesale distribution of medicines and advice to out-patients". I subjoin the passage in the newspaper to which I refer:—

"CHELTENHAM GENERAL HOSPITAL. ANNUAL MEETING. The annual meeting of the subscribers to this charity was held in the Board Room on Monday last; the President of the institution, F. Monro, Esq., in the chair. There were only from fifteen to twenty subscribers present, including the Revs. F. Close, F. D. Gilby, and C. B. Trye; Messrs. Tart, Basevi, C. T. Cooke, Humphris, D. J. Humphris, G. E. Williams, G. A. Williams, W. Hasell, T. Henney, Brandon, Iredell, Bradshaw, R.N.; and Drs. Gibney, Dalton, Comyn, Hawkins, Cannon, Bagnell, etc.

"PAUPER PATIENTS. Mr. DALTON, surgeon, took the opportunity, at this stage of the proceedings, of handing in a cheque for £10 from the guardians of the Winchcomb Union, with a request that its receipt might be acknowledged to Mr. Trenfield, the clerk to that union. He (Mr. Dalton) also took the opportunity of saying, that it was much to be regretted that the guardians of the different unions were in the habit of recommending pauper patients to these institutions, to the injury and loss of the hard-working surgeons of the unions. He did not speak on his own account, as he did not now fill the office of medical officer."

union; but he knew, from experience, that such a practice existed. "Mr. TARTT said, as far as the institution was concerned, it was out of their power to refuse any patient who came to them suffering from a casual accident.

"The Rev. Mr. TRYE regretted that Mr. Dalton had left the room, for he was quite sure that the guardians were not open to the imputation cast upon them; indeed, the impression out of doors was quite the other way, namely, that a great many cases were treated by the union medical officers, which ought by rights to be brought to the hospitals. (Hear, hear.) It was impossible that the poor could be treated so well in their own confined cottages as they could be at an institution like this. Then it was only a common act of charity to bring them here; and he was quite sure that no medical gentleman of any standing would complain of such a thing. (Hear, hear.) He believed the practice Mr. Dalton complained of received the sanction of the Poor Law Board.

"Dr. HAWKINS. Yes! and the Poor Law Board recommends that, in parishes where there are hospitals, the Board of Guardians should subscribe to them, so as to have a right to send patients to them.

"The Rev. Mr. TRYE. For the express purpose of relieving the rates.

"Dr. HAWKINS. Yes.

"The Rev. Mr. CLOSE. I thought that Mr. Dalton's ten pounds and his speech did not tally very well together.

"Mr. G. E. WILLIAMS. I ought to say, that I have known my friend Mr. Dalton for many years, and I am quite sure he is the last man to make any complaint which he did not believe to be correct.

"The matter then dropped."—*Cheltenham Journal*.

I much fear that it will be more difficult than you imagine, to convince committees of public charities that anything is an abuse which brings grist to their mill. They consider their responsibilities simply to consist in sustaining and enlarging the benefits of the charity; and think little, and care less, respecting the rights of their medical officers. Medical men, therefore, in their attempts to establish themselves in a more just and remunerative position, must take higher ground than that upon which any memorial to a body of exclusive executives can possibly be planted; and at once insist on their right to be placed in the same position as their brethren of the kindred professions, who, as in the instance in question, are often more ready to oppose, than to support them.

If it be true, that they who wait by the altar should live by the altar—that the labourer is worthy of his hire—the barrister of his fee—the soldier of his pay,—why should we not decline to continue a practice which (to use your own words) "tends to diminish the public estimation and proper money value of professional advice"? The tactics of the day point out to us that the only chance of success lies in agitation; and, as a first step in the right direction is half the battle, let every hospital and dispensary practitioner place at once before the public the alternative—*remuneration or resignation*. It may be that, for a time, inferior persons may supply the vacated places; but John Bull has too much good common sense not to perceive that he has but "gained a loss" by the substitution of the raw recruit for the experienced man.

JUSTITIE AMATOR.

IMPORTANCE OF MEDICAL HISTORY.

LETTER FROM HENRY DAYMAN, ESQ., TO THE EDITOR.

SIR,—I have read with much interest your articles on the "Study of Medical History, as a necessary part of Medical Education"; and they have suggested to me a few remarks, which I now offer, partly in extension of your own opinions, and partly to vindicate the claims of that old-fashioned scholarship on which the apparent success of modern science may have cast a slur.

In spite of the objections which some of your readers have raised, I venture to affirm that every thinking person, who has looked into the matter, is satisfied that the ulterior advantages you have set forth, are real; and that your words have not been the mere expression of a fanciful theory. But, since there is one result to be looked for, to which no allusion has been made, and since the operation of that result is immediate, and requires neither special pleading to enforce, nor a mind unusually credulous to take in, perhaps it will not be out of place to draw attention to it at once. It is the profit in store for those who investigate the means by which the great men of old have achieved their greatness. Let us take one example, then which there is none more striking on record. The history of Harvey's

celebrated discovery is well known. The doubts and difficulties which for a long time, in the face of positive demonstration, prevented the doctrine from being established, have been often narrated. The reserve of the public, and the opposition of the profession, were equalled only by the firm and deliberate perseverance of the illustrious author himself. But, I would ask, may we not trace the success which at every step followed this great induction, to the influence of the dialectic school in which Harvey had been trained?

On the other hand, it may be urged, that instances are not wanting of men who have attained eminence by the unassisted energy of their natural gifts. Of this sort was John Hunter: and while we confess that education can lay down no laws for the guidance of such minds, since it is of the essence of genius to endure no bounds but those of its own imposing, it may be well worth our while to attempt an analysis of the principles which have actuated and supported these master-spirits in their career.

To a careless observer, many of the speculations of John Hunter must at first have appeared like the dreams of an enthusiast; and, indeed, if the determination of purpose which he manifested throughout life had been exhibited only by fits and starts, as if he obeyed no adviser but caprice, his efforts of thought might, to say the least of it, have been justly charged with inconstancy. But it was far otherwise with John Hunter: he had consecrated his life to the fulfilment of a divine mission; and the subordinate failings of his mind (of which hasty temper was a conspicuous one) had no power to withdraw him from his great work: he never relaxed from that disinterested activity to which, as if by a severe necessity, he had been wrought up; and of which, on the other hand, there was no perceptible increase. It may, therefore, be said of John Hunter, that his mind presented "the calmness of an intensity kept uniform by the nature of the human mind forbidding it to be more, and by the character of the individual forbidding it to be less. The habitual passion of his mind was a pitch of excitement and impulsion, almost equal to the temporary extremes and paroxysms of common minds; as a great river, in its customary state, is equal to a small or moderate one when swollen to a torrent."

Becoming thus personally acquainted, so to speak, with the fathers of our art, the student would discover by what methods they earned for it the epithet *learned*; and that this distinction was bestowed on medicine, not in consequence of their attainments in medical information, but from their intimate knowledge of the mechanism of the instrument through which that information was conveyed. Our ancestors both wrote and spoke in the Latin tongue; and it was their wisdom to believe and teach that science could only be known when its language was understood.

There is yet another point connected with this subject, which is well worth our attention: I mean the effect which the study of history would be likely to have on the *style* of medical composition; for I hold, that a general standard of excellence may be observed in medical, no less than in every other kind of writing. Nor does the introduction of technical terms, which is indispensable in the language of science, necessarily weaken the force, or take from the purity of the style. The ancients would certainly warn us not to burden the sense with hard words: above all, they would remind us that we are forbidden, equally by the canons of good taste and the laws of universal scholarship, to coin words from the Greek or Latin languages, which may be given as well in plain English; or to thrust into the currency of our literature an alloy compounded of Latin and Greek roots. I cannot but think that such words as "mentalisation" and "sociology" are tainted with this vice.

Lastly, I would ask your objectors to consider the means by which the efficiency of editors themselves is secured; but I must defer this and other parts of the subject to a future opportunity.

HENRY DAYMAN, Surgeon.

Milbrook, Southampton, Feb. 5th, 1853.

FORMULA FOR TIC-DOULOUREUX.

LETTER FROM J. W. BEAUMONT, ESQ., TO THE EDITOR.

SIR,—Those who have seen a patient suffer from an acute attack of facial neuralgia, when the pain has been so intense as to render life, for the time being, burdensome, will surely rejoice when anything is suggested likely to give relief. Having had a very large number of cases to treat, I have tried almost every remedy and almost every combination, but have found none so efficacious

as the following. It is one for which I do not for a moment claim novelty; but having seen so much good from it, I cannot forbear, on grounds of humanity and benevolence, from communicating it to others. It is as follows:—

R. Ferri potassio-tartratis ʒij.
Vini opii ℥lxxx.
Aqua cinnamomi ʒviii.

M. Ft. Mist.

Give two tablespoonfuls three times a day, or three tablespoonfuls at once, if the pain be very severe.

I do not pretend to say *why* this particular combination should be *apparently* so much better than others, but certainly I have not known it yet to fail.

J. WILSON BEAUMONT, M.R.C.S.,

Late Resident Surgeon of the Wakefield Gen. Dispensary.

Mirfield, Yorkshire, February 5, 1853.

PETITION AGAINST THE INCOME TAX FROM THE PRACTITIONERS OF SHREWSBURY.

LETTER FROM DR. BURD TO THE EDITOR.

SIR,—A petition, similar to the one agreed upon by the medical men at Torquay, has been signed by all the medical practitioners in Shrewsbury; and Mr. E. H. Baldock (one of our borough members) has kindly consented to present the petition, and urge its prayer by every means in his power. I hope that the members of the profession in other towns will also follow the good example of their Torquay brethren, and raise an unanimous voice against such a continued injustice.

EDWARD BURD, M.B. & L.M.Cantab.

Shrewsbury, Feb. 7th, 1853.

THE NECESSITY OF PETITIONING AGAINST THE INCOME-TAX.

SIR,—Parliament has already assembled; but what has the profession done to relieve themselves from the unjust oppression of the Income-Tax? A great effort, on the part of the Provincial Medical and Surgical Association, could not fail to produce a powerful impression. This might either be accomplished by the assembling of a Special General Meeting at some central or convenient place, such as Birmingham or London; or by the Branches holding special meetings, and petitioning separately. The Income-Tax Committee of the Provincial Medical and Surgical Association cannot be expected to accomplish any beneficial result, unless they receive, in some such way as I have suggested, the countenance of their colleagues.

I am,

A VICTIM OF THE INCOME-TAX.

February 8th, 1853.

NEWS AND TOPICS OF THE DAY.

THE LETTSOMIAN LECTURES of the Medical Society of London will be delivered this year by Professor Murphy, commencing on the 9th of March. The subject which he has selected is "Parturition as illustrating the importance of a competent education in the practice of midwifery".

GLASGOW MEDICAL JOURNAL. The prospectus has appeared. The work is to be published quarterly; and No. I. is advertised to come out on the 1st of April. We understand that we were correct in naming Dr. Weir as the editor. It is evident from the prospectus, that this new medical periodical is started, not as a commercial speculation, but for the praiseworthy purpose of fostering local talent and industry.

MEDICAL BENEVOLENT COLLEGE. We recently announced, that the Bishop of Oxford had kindly consented to preach in Vere Street Chapel, in aid of the funds of the College. We have now the satisfaction to state, that the Bishop of London has promised to preach, in Trinity Church, St. Marylebone, in furtherance of the same object.

BATH UNITED HOSPITAL. At the annual meeting of this institution, P. B. Duncan, Esq., in the chair, it was stated, that during the year, the in and out patients numbered 13,976. The receipts amounted to £3,739 14s., and the expenditure to £3,536 5s.

INCREASE OF LUNACY IN MARYLEBONE. In the first half of 1851, there were 316 in the asylums and workhouses of the parish; in the first half of 1852, that number had increased to 494, being an addition of 180 lunatics to those already chargeable on the funds.

DR. DALTON. A proposal is on foot to erect a statue in memory of the late Dr. Dalton, the author of the atomic theory, in the Ardwick cemetery, where his remains were interred, and to found two scholarships in Owen's College, Manchester, one chemistry in and the other in Mathematics, the learned doctor having been eminent for his success in applying mathematics in the elucidation of chemistry. The Mayor and the Bishop of Manchester are earnest in supporting the proposed subscription.

SUSSEX AND BRIGHTON EYE INFIRMARY. During the year 1852, there were admitted 1,359, being a considerable increase of patients on the previous year. The late Clement Deacon, Esq., bequeathed £448 17s. 6d., and N. A. H. T. presented a donation of £100. Two wings were lately added to the Infirmary, which have increased the beds to twenty-eight.

ADVERTISEMENTS.

Just Published, 8vo, cloth, 8s.

On Consumption: its Nature, Symptoms, and Treatment.

Being the Essay for which was awarded the Fothergillian Gold Medal. By RICHARD PAYNE COTTON, M.D., Assistant-Physician to the Hospital for Consumption, Brompton.

"A work of very considerable interest."—*Medical Times*.

"Eminently calculated to remove many of the difficulties which surround the subject."—*Lancet*.

"A very excellent practical treatise, which deserves, and we have no doubt will have, extensive circulation."—*Dublin Medical Press*.

Also by the same Author, foolscap 8vo, 3s. 6d.

Phthisis and the Stethoscope. A Concise

Practical Guide to the Physical Diagnosis of Consumption.

London: JOHN CHURCHILL, Princes Street, Soho.

NEW EDITION OF WILSON'S PRACTICAL AND SURGICAL ANATOMY.

On Friday, February 18th, will be published, in One Volume, with additional Wood Engravings by Hagg.

The Dissector's Manual: Being a

New Edition of Practical and Surgical Anatomy. By ERASMUS WILSON, F.R.S.

London: Longman, Brown, Green, and Longmans.

DISEASES OF THE BREAST.

One Volume, 8vo, with 12 plain and coloured Plates, price 12s. 6d. cloth.

The Diseases of the Breast, and their

TREATMENT. By JOHN BIRKETT, F.R.C.S.E., F.L.S., Assistant-Surgeon to, and Lecturer on Anatomy at, Guy's Hospital.

London: Longman, Brown, Green, and Longmans.

IN THE PRESS.

An Account of some of the Less

FREQUENT DISEASES AND DANGERS OF PREGNANCY AND PARTURITION. By JOHN ROSE CORMACK, M.D.

London: TAYLOR, WALTON, and MABERLEY.

Second Edition, greatly enlarged, with thirty Woodcuts, price 7s. 6d.

On Near Sight, Aged Sight, Impaired

VISION, and the MEANS OF ASSISTING SIGHT. By W. WHITE COOPER, F.R.C.S., Senior Surgeon to the North London Eye Infirmary, and Ophthalmic Surgeon to St. Mary's Hospital.

London: JOHN CHURCHILL, Princes Street, Soho.

Osteological and Dental Repository.

45, Museum-street, Bloomsbury, London. JOHN HARNETT begs most respectfully to call the attention of Lecturers, Students, and Gentlemen connected with the Medical Profession, to his large and select Stock of Anatomical Preparations, consisting of Skeletons, loose and articulated Skulls, Hands and Feet, Vertebrae, and Loose Bones, at the lowest possible prices.

NOISELESS RINGS.

Gutta Percha Curtain and Cornice

RINGS.—These Rings have been much approved by the Faculty, particularly for nervous and aged persons. Owing to the peculiar properties of Gutta Percha, these rings do not make a noise when drawn along the pole or rod. The following sizes may be had either with or without loops.—Sizes, 1 inch diameter, 1½ inch ditto, 2 inch ditto, 2½ inch ditto, 3 inch ditto, 3½ inch ditto.

TUBING, LINING FOR TANKS, ORNAMENTAL MOULDINGS, &c., manufactured by the GUTTA PERCHA COMPANY (Patentees), 18, Wharf-road, City-road, London.

[ADVERTISEMENT.]

13, PIERREPONT STREET, BATH,

3rd February, 1853.

SIR,—As my Letter is not allowed admission into the body of our JOURNAL, I request you will place it extra limites, and that you will publish this with it.

I am, Sir, your obedient servant,

JOHN BARRETT, F.R.C.S.

To Dr. CORMACK,

Editor of the Association Medical Journal.

TO THE EDITOR OF THE ASSOCIATION MEDICAL JOURNAL.

SIR,—The publication in the PROVINCIAL MEDICAL AND SURGICAL JOURNAL for December 23, 1852, of a discussion affecting my character—a proceeding, I believe, without precedent in the history of the Branches; the very great irregularity, according to all laws of debate, of interrupting me, whilst in possession of the meeting, by a motion not even put as an amendment to that before the meeting; the impossibility of my afterwards defending myself under protest, as I otherwise should have done, without admitting a right which I cannot think of admitting; and the common justice there is in allowing every man an opportunity of defending himself when attacked (and, virtually, I have been again attacked by the publication of this report)—oblige me to request your insertion of the following remarks.

I shall not, however, argue on the right claimed by the meeting of considering such questions. I protest against it; and the manner in which that right has been supposed to be established, and which is really nothing more than the old "*sic volo, sic jubeo, stet pro ratione voluntas*", will not deter me, when occasion arises, from arguing against it. But I should prefer such an occasion, as would in itself clear the arguments I might use from all appearance of being influenced by personal considerations.

In my letter, which has been appended to the report of the meeting, it is stated why, with Mr. W. Bush, I volunteered my evidence in Mr. Cox's favour. With the trial, I think, the subject ought to have rested. In and out of the profession, I was not singular in this opinion. But there it was very soon determined that it should not rest; within two or three days, the programme for Mr. Cox's ruin was out. He was to be driven with ignominy from this Society and that; to be stripped of his appointments; the College of Surgeons was to be applied to, to demand his diploma; and then, disgraced himself and his family beggared, he might hide himself in one of our colonies—an emigrant, if not an outcast.

However galling it may be to his enemies, events have shown that a man who, for a series of years, has conducted himself kindly and honourably, cannot be thus crushed. *Nemo repente turpissimus fuit*. The public has felt this; and his patients have shown that they do not believe the charges against him. Nor have his own patients been the only ones to show this. To attack another man behind his back, is always a mean, and sometimes a dangerous, course. That attack is still going on. It will prove as futile as it is contemptible.

When Mr. W. Bush and myself left the court, we had no intention of having anything more to do with the matter; but when we saw what was contemplated, we did not feel justified in standing by and seeing a man crushed, most unjustly, as we did then, and still do, believe. But how was our object to be effected, except by showing the public that the adverse evidence was not to be depended on? By far the most important part of this evidence was that of the medical men: it was this on which mainly rested the counsel's allegation of fraud. It was put to the jury by the judge, and he did not desire "the jury to dismiss the medical part of the case from their consideration"; he did not recommend "the jury to look at the broad facts of the case, and not the evidence of the medical witnesses". It was necessary to bring before the public, in such a manner as they could understand, such an array of argument and authority as would upset it. It would have been idle to have confined ourselves to the medical profession: they did not require information on the subject. With the public, not with the profession, rested the question of Mr. Cox's ruin.

We were not the first to introduce the subject to the public;

nay, more, to the drawing-room, to the ladies. The Bath papers had already given full reports of the trial: the editor of one had written a leader on it. We found the subject in the hands of the public, and there we dealt with it.

It is objected, that my letter had a tendency to injure the medical witnesses. My answer is, that their evidence had a tendency to ruin Mr. Cox, and if erroneous, as I contend it was, to ruin him unjustly. But, if what I stated against them be true, they, at any rate, suffer only from truth being against them; whilst Mr. Cox might have been ruined from their error being against him. I disclaim all personal ill will towards them. I readily acknowledged their respectability when attacking their opinions. Nothing I have written would have been illegitimate, had it been suggested to Mr. Cox's legal defender at the trial; and then the press would have made it public. Would the press have been immoral in doing this? Then it has to answer for immorality in what it has published. Let this Branch of our Association arraign the press, appoint their champion, arm him with their most tried weapons;

"And when he thus doth ride abroad, may I be there to see."

I had no selfish object to serve in writing this letter. I have lived to very little purpose, if I have not long since learnt that, in taking such a step as I have in favour of a just though unpopular cause, a man exposes himself to much that is unpleasant, much that interferes with the ease of life. "*Nonne melius multū fuisset, otiosam ætatem et quietam, sine ullo labore et contentione traducere*." Were I a disciple of Epicurus or Paley—did I believe that ease or expediency should be our guide, I should certainly have acted on the suggestion which Tully did not follow.

It was not that either Mr. Bush or I justify the introduction of such subjects to the public under ordinary circumstances. We need not deal in protests when facts are so ready to our hand. I am sorry to occupy your space; but it is more just to give in full the following extract from the report of the "Anniversary Meeting of the Bath and Bristol Branch", as it appears in the JOURNAL for 1850, p. 412:

"Mr. Hunt here rose to make some strictures upon the manner in which their reports had hitherto appeared in the provincial newspapers. He had no objection to the publication of the reports, if the list of cases were left out; but to publish that such and such a case was read by so and so, savoured of quackery, and did not accord with the respectability of the profession. He therefore moved an amendment, to the effect that the list of cases should not be published in the report. The Secretaries defended the publication of the list of cases in their report, and stated, that it had been customary to request one or two local reporters in the town in which their meetings were held, to attend, in order to proclaim to the public their proceedings. They had nothing further to do with the reports in the newspapers; and, unless a resolution were come to by the meeting, that reporters should not be admitted at all, they could not be answerable for the publication of any part of the proceedings. Mr. Norman, and several other of the most influential and respectable gentlemen present, utterly repudiated the sentiments expressed by some of the speakers; and expressed their acknowledgments of the obligation the Association was under to the public press, and to the total absence of any right on the part of the meeting to say to its representatives what part of their proceedings should, or what part should not, be reported in their columns. Mr. Bartrum, as Secretary, especially bore testimony to the courtesy the reporters had always evinced, as well as the judicious character of the reports given of the proceedings of the Association."

This "judicious character" thus highly lauded by the Secretary, will, no doubt, be evident by the following titles, which I extract from the list which Mr. Hunt informs me was that he quoted when complaining of such lists appearing in the newspapers:—"On a Case of Imperforate Urethra; and on a Case of Imperforate Anus"—"History of a Case of Laceration of the Perineum during Parturition": I believe, the only members who spoke in support of Mr. Hunt were myself and Mr. W. Bush; and I clearly remember, that my ground of objection was, that, under the circumstances, there was no sufficient reason for introducing a mention of such subjects to the public; and there were very strong reasons why it should not be done. Were we inclined to use it, the Branch would evidently furnish us with a *tu quoque*. But

"Non tali auxilio, nec defensoribus istis
Tempus eget".

And I will also say,

"*Nec venenatis gravidâ sagittis,
Fusce, pharetrâ.*"

There is far higher ground, there are far better weapons of defence. They resolve themselves into two questions:—Are there no circumstances which justify the introduction to the public of subjects not ordinarily brought before it? Did the occasion on which we acted present such circumstances?

We had to quote and argue on diseases. Supposing it had been necessary to refer to functions, could we find no high authority for such reference? Say that nothing can justify this, aye, and when very broadly done, and you must tear from British literature some of its noblest, its wittiest, nay, its most moral pages. I talk not of the accidents of language, nor even of those occasional blemishes which we bear with, because we cannot remove them without endangering what is so intimately mixed with them, but I mean those deliberate and intentional introductions of such subjects which form part of the character of an author—I mean not those writings which we keep on a dark shelf in our libraries, but those great British Classics which, as fathers, as husbands, as brothers, we do not selfishly confine to our study, but which we place, in splendid binding, and with beautiful illustrations, on our drawing-room tables. What department of British classical literature shall I—or, rather, which may I not—instance in proof? Look at Milton, who wrote

"to assert Eternal Providence,
And justify the ways of God to man."

Read his allegory of Sin; his description of Adam and Eve in Paradise, in the bridal bower; their conduct immediately after the Fall, and when returning conscience alarms for the consequences. And mark how indignantly he justifies such references—goes out of his way to—Ah! he was not a member of the Provincial Medical and Surgical Association, or he would have been better instructed.

Then there was Pope, whose object was to "hit the folly as it flies"; and he hit hard too, by the means in question. Thus he hit the

"reverend sire, whose want of grace
Had made him father of a nameless race";

when he says of him—

"Still to his wench he crawls on knocking knees,
And envies every sparrow that he sees."

Alexander Pope! how could you place this in your *Moral Essays* (Ep. i, 232)? or how could you think of describing what happened to Sir Balaam's daughter (Ep. iii, 392)? or how could you dare to redeem from the difficulties of old Chaucer, and present, in your own flowing numbers, what followed from the union of January and May? Surely we are abettors of your immorality, when we allow you to remain in our libraries, say nothing of admitting you into our drawing-rooms!

Sterne,—you who wrote sermons!—what were you thinking of, when you wrote *Tristram Shandy*? If there be Widow Wadmans in the world, how immoral of you to describe them! Say that the Sorbonne did subtilize till it made theology an indecency, how immoral of you really to defend the dignity of religion, by turning on them their own weapons!

But it is not only in our classical literature, it is also in the best part of our everyday press, that we find these ordinary rules departed from when occasion demands. Look at the extracts the *Times* published from the *Guide to the Confessional*. Is anything I have said half so plain as what is there stated? How many other instances might I quote!

But to come nearer home. It was only last summer, that the Rev. H. Seymour, a clergyman of the Church of England, brought forward in this city, to a crowded meeting, in reply to Cardinal Wiseman, details of conduct the most horribly licentious and disgusting. Ladies, it is true, were not present, but youths were there. I am not censuring the reverend orator; he deemed the occasion justified what he did. So did many of his clerical brethren; so must some of those medical men who censured me the other night, for they clustered round him on the platform. But then they had popular feeling with them,—the cause we espoused had had popular feeling raised against it.

It is not many years since I had to give evidence on a trial of infanticide, before Mr. Justice Erle. Just as females were about to be ordered out of court he interfered and said he wished them to stay, adding "if this case be conducted as it should be, nothing need be said, which under the circumstances

a female should not hear, and for the good of society I wish them to hear." He knew what kind of evidence would be given, for he had the depositions before him; and if a charge rests against me, still more would the evidence then given and which he did not interrupt, make it rest against him. Can that be immoral which an English judge on the Bench sanctions?

"Credat Judæus Apella,
Non ego."

Look at the case of Kirwan, now occupying so painful a part of public attention: is there not at least one point in the medical evidence which demands investigation, which appears to have weighed with the jury, which has most mistakenly been made the foundation of a horrible suggestion in a leading journal, and which could not be dealt with except by the plainest out-speaking on subjects never ordinarily referred to, and to which the attention of the profession has been invited? There life and death tremble in the balance. Would any member of our Association condemn a letter, which was afterwards shown to have saved an innocent life, no matter how plainly it spoke out to the public? He would not. And is the character,—are the best and dearest interests of a professional brother, likewise no sufficient grounds for speaking plainly to the public on subjects to which we would not ordinarily refer? This word "brother" we often use, but if it implies anything, it implies duties on the part of those who use it, rights on the part of those towards whom it is used. I have some grateful recollections of a time when this was felt by others in the profession towards myself. I hope I have not forgotten the lesson.

It has been said that my letter might find its way to the drawing-room table, and pollute the minds of some wives and daughters. Is there not one book which, happily for this country, we place in the hands of every person, without restriction? And do we, therefore, consider ourselves guilty of what is immoral or improper? And yet there have not been wanting those who have said that this book is indecent (*ut quidam minuti philosophi censent*). I do not suspect either of the two gentlemen who attacked me of this. They certainly threw some hard words at me, but I should be sorry to do them an injustice in return. I will, therefore, not class them with those "minute" philosophers who could see nothing but the little difficulties in the aspirations of Cicero, nor with those against whom Berkeley entered the lists; still less will I intimate that they belong to another branch of the same school, who titled mint, anise, and cummin, the trifles of the law, whilst its eternal principles of truth, justice, and mercy, they neglected or outraged. But this I do say, that in such an attempt as they have lately made, they are going on a false principle; that they are paving the way in our profession, it may be unconsciously, for that "minute" moral philosophy which finds its satisfaction in conventional views, and which is ever in danger of losing sight of "those sublime laws of right, which had the ethereal heavens for their birth-place, and God alone for their author; which the decays of mortal nature cannot vary, nor time cover with oblivion; for the divinity is mighty within them, and waxes not old."

And now, in leaving this subject, I have no wish to deny the pain it has given me to differ from so large a number of my professional brethren. I am very far from denying them what I claim for myself,—the credit of upholding what they believe to be right; but there are occasions, in the life of every man, when we have to determine between what we see would be convenient, and what, with all its dangers, with all its annoyances, we deeply feel to be right. On such convictions I have acted; and were I to seek a formula for my medico-ethical creed, I could not find a better than in the language of one who most happily combines the physician, gentleman, and scholar:—

"In nostrâ hæc republiâ, quod verum est, sit pro re—pro imperio, religio veri—pro lege supremâ, populi salus! Sit unitas in communitate, in communitate unitas! Ad hæc tuenda et conservanda sit nullum inter nos jusjurandum! Si ullum, in verba hæc—'Experientia! Amor! Amicitia!' Verba ipsius Harvey—verba omnium ætatum, temporum, locorum! Leges, mores, etiam diplomata regia, humana omnia mutantur. Amor et amicitia a Deo sunt, et manent."

I am, Sir, your obedient servant,

JOHN BARRETT, F.R.C.S.

13, Pierrepont Street, Bath,
29th December, 1852.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. VII.

LONDON: FRIDAY EVENING, FEBRUARY 18, 1858.

NEW SERIES.

THE COLLEGE OF PHYSICIANS OF EDINBURGH AND THE UNEQUAL PRESSURE OF THE DIPLOMA STAMP-TAX.

LAST year, during the assembly of Members of the Provincial Medical and Surgical Association at Oxford, a meeting was held by British graduates in medicine practising in England and Wales; and a committee was formed for the purpose of attending to their interests in connexion with the measure of Medical Reform proposed by the Association, and the contemplated charter of the London College of Physicians. This committee has not been asleep; and through their energetic secretary, our colleague Dr. Tunstall of Bath, they have been in useful and friendly communication with the Royal Colleges of Physicians of London and of Edinburgh. From a correspondence published in the former series of this Journal, for December 8th, 1852, p. 648, between the Secretary of the Graduates' Committee and the Registrar of the London College of Physicians, it appears that the latter body entertain no unkindly feeling towards gentlemen practising as physicians in England and Wales without their license, and are desirous, by a fair and liberal scheme, to incorporate all physicians practising on this side of the Tweed into their College, under the then appropriate name of the Royal College of Physicians of England. In fact, throughout the recent negotiations and public discussions arising out of the publication of the Medical Reform Bill by our body, it has been universally felt that the London College of Physicians of the present day is sincerely disposed to concur in and promote any measure which is calculated to benefit the profession; and that they are resolved on the one hand to co-operate with our Association in obtaining a just and liberal bill, and on the other to assist in carrying *pari passu* through Parliament charters for the Scottish and English Colleges of Physicians, by which all honourable practising physicians should be incorporated into the Colleges of their respective kingdoms. We are only stating the expressed opinion of the profession both in England and in Scotland, when we declare such an incorporation to be wise and conciliatory in its immediate consequences, and bountifully fraught with future benefits to legitimate medicine, especially by its protecting us better than at present from the degrading taints of homœopathy, and other money-paths, by which needy or greedy men, under the assumed cloak of physic, endeavour to enrich themselves.

To facilitate the accomplishment of so desirable an object as this general incorporation of physicians, it is evident that a vigorous effort ought to be made by the parties more immediately interested, to induce government to remit the diploma stamp-tax during the year of grace proposed by the new charter; so that so unfair and onerous an impost should not in any degree be allowed to shut the door which the College of Physicians of London are about to open.

Impressed with this conviction, the Committee of British Graduates considered how they could best bring influences

to bear upon Government; and, among other steps which they deemed proper, they stated the case to the College of Physicians of Edinburgh. It was found that that active and enlightened body had already deliberated upon the question, and were prepared, upon every fitting occasion, to urge a remission of the objectionable stamp tax. On the 1st current, they adopted the following petition to Parliament, which very clearly exposes the flagrancy of the grievances complained of:—

Unto the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The Humble Petition of the Royal College of Physicians of Edinburgh, given under their common seal this first day of February, one thousand eight hundred and fifty-three years,

HUMBLY SHEWETH—

That your petitioners were incorporated by Royal Charter in 1681.

That this Royal Charter points out the advantage of having all the Physicians incorporated into a Royal College, and renders it imperative on those practising in Edinburgh to belong to it.

That by the aforesaid Charter no one can be admitted a Fellow of the College of Physicians, unless he has graduated in medicine in some University.

That comparatively recently a tax of £25 has been imposed on the diploma of every Fellow of the College.

That a similar tax of £10 is imposed on the diploma of every graduate of a Scottish University.

That as most of the Fellows of this College are graduates of one or other of the Scottish Universities, they thus pay to Government in this tax the sum of £35.

That the diplomas of graduates in medicine of the London University, and of the Queen's University, in Ireland, are not liable to this duty.

That many Fellows of the Royal College of Physicians of Edinburgh have removed to England, and are there engaged in practice.

That the new Charter of the Royal College of Physicians of England contemplates the admission of these gentlemen into that body at a fee of £15; and that the Royal College of Physicians of Edinburgh are of opinion that it would be of great advantage to the profession and to the public, were all practising physicians incorporated into the Colleges of their respective kingdoms,—an arrangement which has been aimed at in every Bill for Medical Reform introduced into Parliament.

That by the existing Stamp Acts, Fellows of this College, joining the College of England, will have again to pay a tax of £15.

That it appears to your petitioners unfair and injurious that the graduates of Scottish universities thus situated should thus pay three taxes: *first*, on graduation; *second*, on admission to the College of Physicians of Edinburgh; *third*, on admission to the College of Physicians of England.

That it also appears to your petitioners that the exemption in favour of the London University, and Queen's University of Ireland, which are new institutions, entirely supported at the public expense, is calculated to injure the schools of medicine in Scotland, by creating an invidious distinction, which ought not to exist.

May it therefore please your Honourable House to take the premises into your early consideration, and to amend the existing Stamp Acts, so as to place all graduates in medicine on an equal footing.

And your petitioners, as in duty bound, will ever pray, etc.

Signed and sealed by the PRESIDENT and SECRETARY, in name and on behalf of the Royal College of Physicians, at Edinburgh, this first day of February, eighteen hundred and fifty-three years.

COURT MARTIAL ON THE CONDUCT OF MR. UMPHELBY, IN RELATION TO MILITARY ETHICS.

DUELLING is likely soon to become—if it be not already so considered—as ungentlemanly a means of adjusting a quarrel or avenging an insult, as it is undoubtedly an absurd and unchristian practice. The altered tone of public feeling upon this subject has, we believe, been brought about partly by enlightened and powerful articles which have from time to time appeared in the *Times* newspaper, but chiefly by its having transpired that linen-draper, tailors, and “snobs” in general, were in the habit of “demanding satisfaction”, and giving and receiving it by firing pistols at one another, charged with ball or blank cartridge according to the discretion of the seconds—just as obtains, or did obtain, among men of undoubted fashion. What was unassailable on the ground of its absurdity, brutality, and sinfulness, has not been able to withstand the imputation of snobbishness: a fact which clearly proves that a satire is often better than a sermon, and that we ought not to ascribe unmitigated levity to the Frenchman when he cries, *Vive la bagatelle!* nor undervalue the services of our eccentric, but true-hearted and most useful contemporary, Mr. *Punch*.

The circumstance of a young medical officer of the Bengal Army having been lately tried by a court martial, for *not* sending a “hostile message”, in the old and till lately approved style, to a fellow by whom he had been wantonly assaulted, has elicited a trial and a verdict for which every rightly constituted mind must feel deeply thankful. The verdict not only does full justice to the courage of our colleague, Mr. UMPHELBY, in refusing to comply with a misnamed code of honour, but it likewise shows that a soldier and a gentleman need no longer fear being cut or cashiered, should he decline to sin against the laws of God and man by fighting a duel with every tipsy comrade or reckless bully by whom he may be injured or insulted.

Mr. Umpelby was put on his trial

“For conduct disgraceful to the character of an officer and a gentleman, in having, at Calcutta, on July 7, 1852, subjected himself to the indignity of being publicly kicked by Mr. A. P. Pennefather, a clerk in the office of the Administrator-General, without adopting any sufficient measures, either immediately, or for three days, to obtain reparation for such insult.”

The court martial returned a verdict of “NOT GUILTY”, and “honourably acquitted” the accused. This decision has been “approved and confirmed” by the Commander-in-Chief; so that we trust and believe that duels may never more be heard of in our armies.

THE MEDICAL SOCIETY OF LONDON AND THE SCIENCE OF PHYSIOLOGY.

MANY of our readers have probably seen, in the *Athenæum* of last week, a report that a movement is on foot for establishing a physiological section, in connexion with the Medical Society of London. We have ourselves been aware for one or two weeks past that such a scheme was in contemplation, and have only been waiting to see the matter in a further state of development, in order to comment upon it. The course pursued by our excellent contemporary

has removed this hesitation; and we proceed, therefore, to place before our readers such information as we possess on the subject.

It is true then, that the attention of the Council of the Medical Society of London has been directed by one of the Fellows of the Society (Mr. Richardson) to the importance of forming a section devoted solely to the prosecution of physiological investigations; and a series of propositions from that gentleman are, we believe, at this time before the Council of the Society, and are receiving its best attention. We cannot state more concerning the extent and nature of these propositions than has been stated in the *Athenæum*; viz., that “the Members of the section are to meet in the rooms of the Society; and that it is proposed that persons not belonging to the Society shall be permitted to join the section”.

It is scarcely requisite for us to say, that the project meets with our fullest approbation. It is not creditable to the scientific world of London to be without a society specially devoted to physiological studies; and the more so, because in this day the applications of physiological knowledge to the practice of medicine and surgery are universally acknowledged and acted upon. We like, too, the principle involved in the present project, that of making the new institution a section of another institution, rather than a separate Society; and are delighted to know that so active and flourishing a body as the Medical Society of London has been requested, in the present instance, to consider the practicability of this principle. If we might be allowed to make one observation on the manner in which sections should be added to standing societies, it is this: that, while it should be the object of the section to further in every way the interests of the parent institution, it should also be the object of the central society to allow the members of the section, within certain defined limits, the power of self-government, and such freedom of action as is due to gentlemen and to scholars.

In conclusion, we have only to add, that we shall watch the further development of this movement with great interest; and shall be happy to offer every assistance which it is in our power to bestow, to a society formed for the purpose of prosecuting with sincere zeal the all-important science of physiology.

THE VERDICT AGAINST MR. HICKS.

WE have inserted at p. 156 a letter from Mr. BENSON referring to our article in the number for February 4th, p. 95, on the verdict of manslaughter recently returned against Mr. Hicks, of Toddington, by a Coroner's Jury. While the force of our general remarks is in no way impaired by Mr. Benson's statements, his share in the case is deprived of some of the grounds upon which our remarks might be made personally applicable.

A DUELLIST, according to Samuel Johnson, is:—“1. A single combatant: 2. One who professes to study the rules of honour.” In exemplification of the latter sense, he quotes the following from Ben Jonson:—

“His bought arms Mung not liked; for his first day
Of bearing them in field, he threw 'em away;
And hath no honour lost, our duellists say.”

ORIGINAL COMMUNICATIONS.

REPORT OF THE READING PATHOLOGICAL SOCIETY FOR THE YEAR 1852.*

By T. S. LITTLE, Esq.

(Read on the 4th of August, 1852.)

MALIGNANT DISEASE. Mr. GAMBLE presented a specimen of encephaloid disease, which had perforated the skull of a man aged 56. He was a pauper patient, of short stature, sallow complexion, and dark hair; he had usually enjoyed good health. A year ago, the disease was first accidentally noticed, and then it formed a flattened and rather hard tumour of about the size of a crown-piece, occupying the upper part of the temporal fossa. It gradually increased in size, and, in the last month, occupied the space bounded by the parietal eminence behind, the orbit in front, the median line above, and the zygoma below; its circumference was very irregular, and it had many offshoots. It was soft, very elastic, and not painful; the skin was but little discoloured; numerous large veins and the temporal artery ramified over it. The edges of absorbed bone were easily felt around the main part of the tumour; they were irregular, very elastic, and denticulated. The shape of the head was much altered, and the right eye protruded considerably. The patient had no headache, nor any disturbance of the cerebral functions, till three days before his death, when, after violent shivering, he had epileptic fits, became semi-comatose, and died.

Post mortem Examination. The cranium was very thin; a portion of it, as large as a crown-piece, was entirely absorbed, and through the opening thus formed the main portion of the tumour protruded: there were also smaller openings through which other portions of the tumour had escaped. The tables of the bone forming the edge of the large opening were widely separated, whilst those of the smaller openings were not. The encephaloid mass adhered to the dura mater and to the bones, and considerably involved the external tissues. Its consistence was tolerably firm and white, except in the centre, where it was soft, and dark from the presence of blood. The outer portions were much softer than the central mass. The brain was healthy, but considerably flattened by the pressure of the tumour.

Mr. Gamble thought that the disease had originated in the diploë.

Mr. BULLEY presented a fine specimen of osteosarcoma, which occupied the right wrist and part of the ulna. The tumour measured fourteen inches in circumference, and nine inches from side to side, and consisted chiefly of bony cells.

The patient was an ostler, aged 46. Sixteen years ago, a horse kicked his right hand, bending it violently backwards: this injury occasioned active inflammation, which terminated in ankylosis of the wrist. A few months afterwards, a tumour arose on the back of the wrist, and acquired considerable size: it was punctured, and a quantity of fluid discharged. Other treatment was adopted, but without benefit. The tumour enlarged, increased in hardness, and then remained almost stationary. He was advised to allow nothing to be done to it, and he resumed his occupation. A few months ago, he received a blow on the tumour; the skin was broken, and there was smart hæmorrhage. This was soon followed by darting pains in it, and by dark red patches on its surface; fistulous openings formed, and from them there was much hæmorrhage; the pain became especially severe at night, and the strength was rapidly failing. Amputation was performed about three inches below the elbow-joint. The patient soon recovered; and two months after the operation was in excellent health.

Mr. HARRISON presented a specimen of cancer of the bladder in a woman aged 70. In September 1851, she was anæmic and cachectic; she had had hæmaturia twelve

months, and the hæmorrhage had sometimes been profuse. A small fungus, protruding from the meatus urinarius, was removed, and nitrate of silver applied. A month later, the bladder was felt, by means of a catheter, to be hard, rugose, and unyielding: there was pain in it. The urine contained mucus mixed with cretaceous masses. After awhile, the pain became agonizing, and a tumour appeared in the right groin. In April 1852, the patient died, exhausted by pain and hæmorrhage.

Post mortem Examination. The bladder was much thickened, and studded with cancerous deposits of various sizes; its mucous membrane was ulcerated in some places. There was a cancerous mass, of the size of a walnut, in the left lumbar region. The kidneys, the rectum, the ovaries, and the uterus, were healthy.

Mr. Harrison cited the authority of Dr. Cross and Professor Walshe, to show that uncomplicated cancer of the female bladder is very rare. Dr. Cowan had seen two such cases.

Mr. VINES presented a specimen of encephaloid disease of the right ovary of a child aged seven and a half years. At the age of five and a half years, the child had occasional pain in the bowels and sickness, and also a red vaginal discharge, which recurred at intervals of three, four, and six weeks. The mammary glands gradually enlarged, and at seven and a half years appeared to be fully developed. About six weeks before the child's death, the abdomen became much swollen and tender, and there was severe pain in it, especially at night. The appetite failed, the stomach rejected all kinds of food, and bilious-looking matters were frequently vomited. She died much emaciated.

Post mortem Examination. There was about a pint of straw-coloured fluid in the peritoneum. The abdomen was nearly filled by an enormous tumour, which had its origin in the right ovary, and weighed four pounds and a half. The left ovary and Fallopian tube were perfectly free. The uterus appeared to be fully developed.

A point worthy of notice in this case, is the coincidence of malignant disease in an ovary with the early development of the sexual organs.

Dr. WELLS exhibited the uterus, ovaries, and rectum, of a woman, who had died in the hospital. When admitted, she was much emaciated: the abdomen was tympanitic, and contained a large tumour. After a few days, vomiting came on, with great prostration. As there had been no evacuation from the bowels, the rectum was examined, and found to be strictured, so that neither a finger nor a tube could be passed up it. In consultation, it was considered inadvisable to attempt to form an artificial anus. Two days afterwards, the patient died.

Post mortem Examination. The left ovary was as large as a child's head; the right was of the size of an orange, and sacculated: it pressed on the rectum. The rectum was obstructed by cancerous deposit, and its canal was not larger than a quill.

During the discussion, Mr. May said that, in any case in which it seemed advisable to form an artificial anus, he would make an opening into the cæcum or ascending colon, by cutting down to the peritoneum, and then applying potassa fusa, so as to produce a slough of that membrane, with adhesion of the intestine; by which all risk of effusion into the peritoneum would be avoided. He considered this mode preferable to that of Amussat, in which the colon is opened behind. He viewed the colon merely as a receptacle, like the bladder, and believed that all the vital functions of the bowels were performed in the small intestines.

PERFORATION OF THE STOMACH. The case was reported by Dr. M'INTYRE, of Odiham, and communicated by Dr. Cowan.

The patient was a labouring woman, of spare habit, who had not been well for several months; she chiefly complained of pain in the epigastrium after meals. In the afternoon of the 23rd August, whilst engaged in reaping, she was seized with violent pain in the left lumbar and iliac regions, and immediately became faint, cold, and

* From the great and increasing demands upon our space, we have been obliged to omit several paragraphs.

covered with profuse perspiration. At half-past nine in the evening, when first seen by Dr. M'Intyre, she was in a state of collapse. There was pain all over the abdomen, but it was most severe on the left side, and was increased by pressure; the abdominal walls were retracted; there was thirst, and the tongue was dry and brown. The bowels had not acted since the morning of the preceding day. The diagnosis was, that perforation of a bowel existed; and she was treated by opium in repeated doses.

August 24th, at 3 A.M., she was easier. At 9 A.M., the extremities were warmer, and the pulse somewhat improved. The countenance was still cadaverous; she had slept a good deal early in the morning, and was still sleepy; the pupils were contracted; there was urgent thirst, and slight retching.

August 25th. She had passed a very bad night, and was evidently sinking. She died at 3 P.M., about forty-eight hours after the seizure.

Post mortem Examination. In the peritoneal sac there were about three pints of green ropy fluid, of the consistence of mucilage. The peritoneum and bowels were highly inflamed, and covered with recent lymph. The stomach was collapsed; on its anterior surface, about two inches from its cardiac orifice, there was a perforation, into which the forefinger easily passed. Its edges were firm, and slightly funnel-shaped; the tissues around were highly vascular and much thickened; near the perforation there was a small superficial ulcer surrounded by slight redness. The ascending and half of the transverse arch of the colon were distended with flatus; the remainder of it was strongly contracted. The lower extremity of the ileum was of a dark purple hue.

CONGENITAL INTESTINAL OBSTRUCTION. Mr. HARRISON related the case of an infant boy, of full size, who two hours after birth vomited large quantities of green bilious fluid; the urine passed freely; everything given was immediately rejected; the vomiting continued to the evening of the third day, when the child died. Injections were tried, but they would not pass; a small flexible catheter was introduced its whole length up the rectum, but it neither brought anything away, nor was it stained by meconium.

Post mortem Examination. The liver was healthy; the right kidney was absent; the stomach and the upper half of the intestines were distended with a greenish flaky fluid; the lower half was extremely contracted; the large intestines were a mere cord dotted with dark matter.

The mother of this boy had had six children, four of whom had died of congenital disease: one of diseased heart, and three of this affection; the first of these lived ten days, the second five days, and the last three days.

PURULENT CYSTS IN KIDNEY. Mr. MAY exhibited a kidney, in which there were several cysts filled with pus: it was taken from a boy, aged 17, who, three days before his death, complained of frequent desire to pass his urine, of pain in the loins, and vomiting.

OBSCURE RENAL DISEASE. Mr. HARRISON presented the kidneys of a man, aged 61, whose principal symptom was rapid breathing with great distress. There was no thoracic disease; the pulse was natural; the skin cool; the urine abundant, and free from albumen. He died more from asthenia than from coma.

Post mortem Examination. The bladder was much dilated and hypertrophied. On the surface of the kidneys there were many cysts filled with sabulous matter; the pelvis and ureter were dilated.

EMPHYSEMA FOLLOWING PHTHISIS. Dr. WOODHOUSE related a case. The patient was a man who had been in the hospital three times during the last eighteen months. On the first occasion, he was under Dr. Woodhouse, and his symptoms were those of confirmed phthisis. He was discharged at the end of his eight weeks. After a few months he was admitted under Dr. Cowan, and, in a short time, again discharged. About a month ago he was re-admitted under Dr. Woodhouse with symptoms of well-marked

emphysema. He was somewhat relieved by treatment; but one morning he suddenly expired in a paroxysm of dyspnoea.

Post mortem Examination. The sternum having been removed, the lungs appeared unusually prominent, on their surface there were numerous vesicles, some of which were of the size of a walnut. In the apices of the lungs there were some tubercles, and some condensed and corrugated points, which were apparently the cicatrices of former cavities; there were also other tubercles surrounded by hepatized lung. The lower lobes were much congested and partially hepatized.

EPILEPSY: LARGE BRAIN. Mr. MAY related the case of a gentleman, aged 40, who for the last fifteen years of his life had been subject to epileptic fits, during which he was generally thrown on his face, and then only rescued from suffocation by an attendant altering his position. In the fits his right humerus had been many times dislocated, but this accident had latterly been prevented by a bandage. He was at last found lying on his face dead, having been suffocated in a fit.

Post mortem Examination. The brain was pale, and weighed sixty-four ounces; the cerebrum fifty-eight, and the cerebellum six.

POISONING FROM BITE OF A FERRET. Mr. JESTON, Jun., related the case of George P., who came to him on the 14th May, complaining of intense pain in the point of one of the fingers of the right hand; the finger had been bitten by a ferret three weeks before. On the 18th, a small abscess was found in the situation of the bite and was laid open. A few days afterwards the patient had a shivering fit, and complained of great weakness, headache, and inability to get out of bed: there was a claret-coloured spot on the cheek and forehead. On the 23rd, the right side of the body was covered with red spots varying in size from a pea to a shilling; the lymphatics of the arm were inflamed, and the glands in the axilla were enlarged: there was great dyspnoea and prostration. Stimulants were freely given, and he began to rally; in a few days the spots disappeared and he got better. On the 27th the left half of the body was affected in the same manner as the right had been: the pulse was sixty; there was great debility, with very slow deep-sighing respiration. A glass of wine or brandy was given every hour; the arm was put into a bath, and the bowels were regulated by enemata. The stimulants were continued, and on the 2nd June the spots had disappeared, and the patient seemed to be going on favourably.

INDUCTION OF PREMATURE LABOUR. Mr. VINES related two cases in which he had performed the operation.

The first was a twin-case. The woman, having had several severe labours, for the completion of which instruments had been used, readily consented to be delivered at the seventh month. On the 21st July, about noon, the membranes were punctured and a great quantity of liquor amnii escaped. In the night of the 22nd, labour pains commenced; on the morning of the 23rd the os uteri was dilating and the pains were strong. The first child was delivered by the feet about noon, still-born, and the second in the same manner about half-an-hour afterwards: the latter was born alive, but died in a fortnight.

In the second case, the woman was of short stature and had an exceedingly narrow pelvis: she had been three times delivered of still-born children; the last of them in the seventh month. On the 22nd Oct., at 4 P.M. the membranes were punctured, and three or four pints of liquor amnii escaped; shortly afterwards she had a shivering fit, which quickly ceased on covering her with warm blankets. In the afternoon of the following day, the child was expelled still-born. The presentation was of the breech. The mother rapidly recovered.

Mr. Harrison said he had induced premature labour twice in the same individual. The first time, in the seventh month, he separated the membranes with a male catheter, and then gave ergot of rye: the labour was completed in

seventy-two hours; the child was born alive, but soon died. The second time, in the eighth month, the membranes were punctured with a stilettoed catheter and the liquor amnii let out; the labour was completed in thirty-six hours: the presentation was a breech one, and the child was asphyxiated. The mother did well.

Mr. May mentioned the case of a lady whom he had attended in two labours, in which he had been obliged to perforate the head. During the third pregnancy he advised the induction of premature labour. Without difficulty he introduced a sponge-tent into the os uteri. The next day he was summoned in great haste: there had been excessive hæmorrhage, and the floor was deluged with blood. He proceeded to deliver her, and then found a placental presentation. Without losing more blood, she almost immediately expired.

PURPERAL BLOOD-POISONING. Mr. HARRISON stated that Mrs. —, aged 36, was delivered of her second child on the 8th March, 1852: the duration of the labour was eleven hours. After the sudden escape of the liquor amnii and when the head was engaged in the outlet, the pains ceased for two hours and a half, then recurred, and, in an hour and a half more, the labour was completed. The outlet was narrowed by an undue prominence of the coccyx; the presentation was face to pubes; the child was a boy and weighed ten pounds: the placenta was extracted in a few minutes; the uterus contracted well, and there was no hæmorrhage.

Second day. She was comfortable in every respect.

Third day. She had been disturbed by the child and felt languid.

Fourth day. She had a good night, and made no complaint. The pulse was 90 and soft; the face flushed, the mouth and tongue dry, and she had slight thirst, the skin was moist, the urine abundant, the lochia moderate in quantity and healthy: there was not much milk. Mr. Harrison concluded that there was a general disturbance of the system, with interrupted secretion. He ordered hydragryi chloridi gr. j.; opii gr. ʒ., quartis horis sumend.; also saline mixture with antimony; and barley water, beef tea, and a little wine and water, for diet; warm water was injected into the vagina, and a hot bran poultice applied to the abdomen for an hour three times a day.

Fifth day, (morning report). She had had a good night: her expression was natural; the tongue moist, clean at the tip and edges, and coated with yellowish fur in the centre. To continue the medicines.

(Evening report). The pulse was more frequent than in the morning; the patient felt perfectly well, with the exception of being a little languid.

Sixth day. She had had a good night; had vomited a large quantity of bile, and expressed herself much relieved, the pulse was as yesterday; the complexion clear; tongue dry in the centre; the bowels had been twice relieved by medicine, and the evacuations were healthy; urine was abundant, and loaded with lithates. She was ordered effervescing medicine with ammonia, soda-water and brandy, and beef-tea.

(Afternoon). The bowels acted three times, and vomiting occurred three or four times. At night the patient felt so well that no one sat up with her. During the night she vomited three or four times.

Seventh day, (morning). She was rapidly sinking. The lochia were now offensive. Some unmixd bile had been once vomited or rather gulped up. Her intellect was clear. There was slight delirium in the evening, and she died at 9 P.M.

Post mortem Examination. A deposit of fresh lymph was found on the ovaria and between the intestinal convolutions. A quantity of bile was present in the stomach and duodenum.

This lady was of remarkably even temperament, and before her confinement was in perfect health. Mr. Harrison attributed her death to the influence of a poison, which was generated in the system, and which the secretory organs were unable to eliminate.

ON DISTICHIASIS.

By WHITE COOPER, F.R.C.S., Senior Surgeon to the North London Eye Infirmary, and Ophthalmic Surgeon to St. Mary's Hospital.

It has been observed by Paley, in his *Natural Theology*, that "in general we may remark in how small a degree those who enjoy the perfect use of their organs, know the comprehensiveness of the blessing—the variety of their obligation. They perceive a result; but they think little of the multitude of concurrences and rectitudes which go to form it".

A forcible illustration of the truth of this is afforded by the affection called distichiasis, in which the simple circumstance of a few hairs growing in a wrong place, or taking a wrong direction, is sufficient to embitter a man's existence. The following case presents a sad picture of suffering from this cause, extending over no less a period than two-and-twenty years.

CASE. Captain R. T., aged 44, 2nd regiment Madras Light Cavalry, was brought to me by Mr. R. J. Pollock, of Kensington, December 18th, 1852.

The following is the official report of his case by the regimental surgeon:—

"OPHTHALMIA. R. T., Captain 2nd Regt. L. C., 25 years resident in India, of a spare habit of body, temperament nervous, habits moderate.

"30th July, 1852. He was placed on sick list on 30th of last month, in consequence of a sprained ankle. Leeches were applied, which removed the pain and swelling; and he has now recovered entirely from that accident, but is suffering so much from his eyes, and his general health is so bad, that there is no prospect of his being able to return to duty.

"Captain T.'s eyes are constantly kept in an inflamed and painful state by trichiasis. There is great redness of the conjunctiva of the eyeball and eyelids; the vessels being turgid with florid blood, forming chemosis. There is considerable opacity of the cornea, rendering vision indistinct; and there is more or less constant pain, and a sensation as if particles of sand, or some gritty substance, had insinuated themselves under the eyelid, accompanied by heat and pricking pain. There is a watery secretion constantly going on in the day-time, that becomes glutinous at night, causing the eyelids to stick together. The eyelids are slightly inverted, and a considerable number of hairs of the upper eyelids are turned inwards against the eyeball; and, although their extraction gives temporary relief, they cause much greater irritation when they begin to grow again.

"This ophthalmic disease is of 22 years' standing.

"When living at Bussorah, in 1829, he had a severe attack of ophthalmia, from which he did not perfectly recover, and was sent to Bombay, and eventually to Europe, for further treatment.

"When in Europe, he placed himself under several eminent oculists; but they did not observe any defect in the eyelids, although he has now reason to believe that trichiasis existed at that time. In England, however, his general health improved, and the disease of his eyes subsided. Soon after returning to India in 1835, his eyes became worse than ever; and he was subjected to a variety of treatment, bleeding, purging, blistering, setons, tonics, alteratives, etc. He had the hairs repeatedly extracted from the cilia; but when they grew again, they took their usual course towards the tunica conjunctiva, and, by constant irritation of that membrane, produced pain and chemosis. Eye-washes and salves were at the same time had recourse to, but all proved ineffectual. His general health became involved; and in 1840, Dr. C. sent him for two years to the Neilgherries, where his health improved; and Drs. B. and S. excised a piece of skin from each eyelid; but the operation did no permanent good. His eyes, on leaving the hills, became as bad as ever. In 1842, he went to Madras, on staff duty, where the oculist endeavoured to contract the eyelids by the application of sulphuric acid;

and on this failing, strongly urged Captain T.'s return to Europe. This, however, he was unable to do, and has ever since remained in India; having the hairs pulled out every week or so, and using nitrate of silver lotion.

"With this palliative treatment, he has continued doing regimental duty: the duty of a cavalry corps constantly subjecting his eyes to irritation, from dust and sand thrown up when at drill. He is now nearly blind, and his general health is bad. He has frequent heaviness and oppression in his head, tenderness and heat in the epigastrium after a meal, and suffers in various ways from dyspepsia, which latter affection is very much aggravated by the depression of spirits induced by the state of his eyes. Altogether, his case is now a very urgent one; and, being clearly of opinion that a speedy return to his native country holds out the only reasonable chance for his recovery, I subjoin the following certificate."*

On taking a general view of Captain T.'s eyes, when he first applied to me, the appearances were as follows:—The upper lids appeared shortened and somewhat thickened; there was a full growth of lashes, which were agglutinated together by thick secretion, which was also accumulated in considerable quantity in the corners of the eyes; there was a constant flow of tears, requiring the frequent application of a handkerchief; the conjunctiva of each eye was reddened, and much stained with the characteristic olive tint produced by nitrate of silver; the corneæ were turbid from deposit of lymph in several places; and there was abrasion of the epithelium in more than one spot.

On examination, the cause of all this mischief was at once apparent. In addition to an unusually luxuriant fringe of eyelashes taking the proper direction, there appeared on the free surface of the margin of each upper lid, an additional row of fine hairs, growing close to the ocular margin, and directed obliquely inwards, so that they swept against the front of the eyes during every act of winking. The right lower lid presented a similar supernumerary row, extending along the greater part of the edge. In the left lower lid, there was a tuft of five strong hairs, which were directed full against the cornea.

The case, taking it altogether, presented a remarkably perfect example of that rare disease, true distichiasis, or double row of eyelashes. I say rare; for, although nearly three thousand patients pass annually under my observation at the two ophthalmic institutions to which I am attached, and elsewhere, three or four cases only of distichiasis (in contradistinction to trichiasis) present themselves.

There was clearly but one course to pursue, namely, to remove the bulbs of the whole of the cilia; for no other proceeding affords complete relief in these severe cases.

On the 21st December, the margin of the right upper lid, including a strip of the integuments, fibres of the orbicularis and hair-bulbs, were carefully dissected from the tarsal cartilage, and the edges of the wound drawn together by sutures.

On the 27th, a similar operation was performed on the left upper lid.

On the 3rd January, 1853, the margin of the right lower lid, and the tuft of cilia on the left lower lid, were removed.

The operations were very painful, and somewhat tedious; but I was ably assisted by Mr. Pollock, and Mr. Baker of St. Mary's Hospital, to whom my thanks are due.

The sutures were in each instance removed twenty-six hours after the operation, and the wounds healed with great rapidity. The following sketches were made immediately after the parts had been removed.

The following extract from a letter from Captain T., dated January 21st, will show his present condition as compared with his previous state.

"Before the operations, my eyes, consequent on the disease I was labouring under, but which was not understood when I returned to England in the year 1832, were continually watering, and in an inflamed state, which caused

great uneasiness and partial deprivation of sight; and until the supplemental row of eyelashes was removed, this irritation was kept up, causing much pain, which ceased on the lashes being extracted with tweezers. I have been suffering upwards of twenty years from this disease. Since the operations I have been quite a different man; my eyes seldom or never water, though they have been so recently cut, and I feel assured that, after they have fully recovered their natural strength, the watering will cease altogether."

Fig. 1 represents the margin of the right upper lid seen from the inner side, and showing the bulbs of the supplemental row of cilia, which are in front.

Fig. 2 is the margin of the left upper lid from the outside. The true cilia are nearest the spectator.

Fig. 3 is the portion removed from the right lower lid, seen from the outside.

Fig. 4 represents the tuft of five strong hairs from the left lower lid; they were directed full against the cornea. With the exception of the last, the false cilia were much finer than the true. In all the sketches, the free surface of the edge of the lid is placed uppermost.

Careful examination of the parts removed confirmed the opinion formed by me from other cases, that in true distichiasis the pseudo-cilia are not merely true cilia, the bulbs of which have been displaced by disease affecting the border of the eyelid, but that they are independent of them, issuing in regular order from the ocular margin, and being much finer than the true cilia. An essential distinction between distichiasis and trichiasis is, that in the former the growth and situation of the inverted hairs is independent of disease of the lid; while in the latter, some morbid condition has almost certainly existed.

The following is perhaps the commonest mode in which the eyelashes become displaced.

A yellow suppurating spot, involving two, three, or more lashes, will be seen at the margin of the eyelid. On lifting with a cataract needle the little scab covering this, a drop of pus escapes, and an ulcer is laid bare, which has dissected round the cilia, often exposing the very bulbs; the cilia having thus lost their natural channels, easily acquire a false direction, which is confirmed by the contraction of the cicatrix after the healing of the ulcer; thus the hairs are drawn inwards against the eye. I have no doubt that this was the cause of the irregular position of the cilia represented in Fig. 5, which was sketched

Fig. 5.

from a portion of the margin of an upper lid, which portion was removed by me on the 8th September, from a patient who had long been tormented with obstinate trichiasis. A comparison of the figures will show the characteristic difference between trichiasis and distichiasis. In fig. 5, the cilia are irregularly scattered over the free margin of the lid; in three out of the four of the other sketches the pseudo-cilia will be seen extending in order along the inner edge of the lid, whilst the true cilia extend along the outer, a clear space intervening between the rows. The fore-shortening in fig. 1 rather obscures this, but it was strongly marked.

The following are the steps of the operation for distichiasis, which after considerable experience, I have found easiest and most complete.

With a fine camel's hair pencil and lampblack, the limits and line of an incision, which shall include all the pseudo-cilia, are to be marked on the skin about the eighth of an inch from the outer margin of the lid; this is desirable, as the free hæmorrhage and loose texture of the parts render

* The usual certificate for return to Europe.

it difficult to preserve an accurate direction during the dissection. Then, with a sharp pair of scissors, the edge of the lid, supported on an ivory spatula, is to be divided at the extremities of the proposed incision. The skin is thus set free; and by means of a sharp scalpel the skin, fibres of the orbicularis, and bulbs of the cilia, may be dissected from the tarsal cartilage with facility. When this strip has been removed, it is proper to wait until the bleeding has ceased, when any stray black points (hair-bulbs) may be snipped out with curved iris scissors. The edges of the incision are to be carefully drawn together with sutures of fine Chinese twist, and cold water dressings alone are required. At the expiration of about twenty-four hours, the sutures should be removed, or the lid will become puffy: their extraction requires a light hand, in order that the adhesions may not be disturbed.

The removal of the edge of the lower lid is somewhat more difficult than that of the upper, for the spatula which protects the eye, and is a firm point on which to cut, cannot be conveniently used; the lid must be drawn down to avoid the possibility of wounding the eye, and the traction on the integuments throws the tarsal cartilage back, so that it is rendered deeper than natural. Instead, therefore, of cutting down, I find it is best to thrust in the point of the knife at the limits of the intended incisions, and to cut towards the surface. The boundaries having been thus divided, the flap should be dissected off the cartilage, and, with a pair of scissors, snipped through close to the mucous membrane.

The operation is painful; the hæmorrhage always free: and it is best to have two assistants, one to hold the head of the patient firmly, the other to attend to the spatula and to sponge.

19, Berkeley Square, February 1853.

ON THE IDENTITY BETWEEN THE POISON OF ERYSIPELAS AND THAT OF PUERPERAL FEVER.

By ROBINSON ELSDALE, Esq., Surgeon.

My object in publishing the subjoined cases is to afford evidence in confirmation of the doctrine of the similarity, or rather the identity, of the poison of erysipelas and that of puerperal fever. They will show that one of these diseases will, under certain circumstances, induce the other; and that the induced disease, acting on the system of another person in a different state, will manifest itself in its original form.

The cases are related in the order of their occurrence.

CASE I. A man in this neighbourhood, after having recovered from a severe and long attack of typhus fever, imprudently went out and sat for some time upon some damp straw. He went home, and was seized with a shivering fit; and in a few hours erysipelas appeared, which extended over the whole of the head and face. He was quite blind from the swelling, and died in a few days. His death occurred on the 22nd of October. During his illness, he had been nursed by the wife of Joseph Freshney, residing at Moulton, a strong, healthy woman, aged 35, the mother of six children. On the day after his death, this woman, being then between four and five months advanced in pregnancy, had a severe rigor, and complained of sore throat. When I was applied to, on October 24th, erysipelas had commenced in the face; and it spread rapidly over the head and neck. Under the usual treatment, however, the fever and other symptoms abated; and on the 9th of November I considered her convalescent.

On November 10th, I was summoned to her, as labour pains had commenced. Shortly after my arrival, a fetus of between four and five months was expelled. I noticed a preternatural degree of heat in the generative organs, which induced me to interfere as little as possible. The woman recovered. Two women who attended this case,

suffered from fever and sore throat, and two children in the house had the same symptoms.

CASE II. On the same evening, Nov. 10th, I was sent for to Mrs. Buchan, a respectable married woman, aged 21, living at Moulton Chapel, four and a half miles from my house, and in quite a contrary direction from the last-mentioned case. She had a very favourable labour—it being her first. I was not with her more than three hours, before she gave birth to a full-grown female child. She had had slight diarrhœa for a day or two previous to the labour, which had not subsided at the time of her confinement. Two days afterwards, she was seized with violent vomiting and increased purging, which continued with more or less violence for a fortnight. There was no tenderness of the body on pressure; but the vomiting, which amounted to some quarts, was to her the most distressing symptom. The fluid ejected from the stomach was of that dark, coffee-ground appearance, observed in puerperal fever; and of precisely the same character as that which occurred in another case about to be related. She had a dry, hard skin, with a pulse never less than 120. The symptoms yielded to medical treatment. Calomel and opium appeared to have a very beneficial effect; and I used turpentine externally. She remained weak for a very considerable time, but ultimately recovered; and I have since attended her in other confinements.

The nurse who attended this woman had inflammation of the arm, which she attributed to a prick from a thorn in the fore-finger. The inflammation extended along the course of the absorbents to the shoulder. She was obliged to leave, and kept her bed for more than a week. She had considerable febrile symptoms. The woman who supplied her place was seized with pain in the arm, without any assignable cause, attended with the same symptoms; and was also obliged to leave. In both cases, abscesses formed, which were exceedingly tedious and troublesome. Both women attributed their illness to washing the linen of the lying-in woman.

CASE III. On the same night, November 10th, I was summoned at half-past 12 o'clock to Mrs. Garton, of Whaplode, quite in another direction from either of the two last-mentioned cases. I had previously attended her in two confinements, both of which had been very quick, and from which she soon recovered. She had enjoyed good health up to the time, and was thirty-seven years of age. On my arrival, I found the membranes whole, with the head low down, and strong pains. I ruptured the membranes, and, after a very few pains, a live child was expelled. The placenta followed almost immediately, and I left her very comfortable. Upon my calling on her during the next day, she (to use her own words) "never felt better in her life". The same night, she was seized with a rigor and pain in the abdomen: this she attributed to some castor-oil which the nurse had given, and which had not operated. I saw her again early on the morning of November 12th, not more than twenty-eight hours after her confinement. She was then suffering from extreme pain in the region of the uterus; she had a dry, hard skin, and a pulse of 140; her countenance was exceedingly anxious and expressive of pain. I bled her in the arm, and applied a dozen leeches to the abdomen: I also ordered her half a grain of calomel, and half a grain of powdered opium, every three hours; and administered an enema of warm gruel with turpentine. Upon visiting her in the evening, I found all the symptoms aggravated. The bowels had not acted; her eyes were half closed, her breasts exceedingly flaccid, her speech incoherent at times, and her breathing very difficult. She was evidently moribund, and died about six o'clock on the morning of the 13th; not living more than fifty-four hours after her confinement.

The nurse who attended her was seized with erysipelas of the face and head, on the evening of the woman's death, and died within a week. I did not attend her myself, as she came under the hands of Dr. Welch, of Holbeach, who told me that he never saw a more severe case, or one which more resisted all attempts on his part to arrest the progress of the disease: in fact, he assured me that it was one of the worst

forms of erysipelas he had ever seen. A neighbour, who came in during the labour, also had an attack of erysipelas, but in a much milder form (owing, perhaps, to her having much less to do with the patient); and she recovered.

Here, then, we have the poison of erysipelas conveyed, as believe, from the first woman, Freshney, producing in the lying-in woman, Garton, puerperal fever, and again (from the difference of the state of the two women) developing itself in the nurse in its original form.

CASE IV. On Nov. 11th, the day following that on which I attended the above-mentioned case, I was called to see Mrs. Brown, a young, healthy woman, aged 21, in labour with her second child. She lived at Moulton Chapel, under the same roof with the second mentioned patient, Mrs. Buchan. Here there was an unusually unyielding state of the os uteri. I had recourse to bleeding and opiates during labour, which extended over sixteen hours. She gave birth to a child greatly deformed in its lower extremities, and with spina bifida. I left her about one o'clock in the afternoon; and upon visiting her again in the evening, I found that she had had a rigor, and complained of pain in the region of the uterus, greatly increased by pressure. I applied leeches, with turpentine dressing, to the abdomen, and gave calomel and opium every three hours, with castor-oil. Upon again visiting her, as there had been no evacuation from the bowels, I administered an injection of warm gruel, with an ounce of spirit of turpentine. I also applied warm poppy poultices, as she complained of the turpentine increasing the pain. The calomel and opium were continued. Next day she was no better. She had violent and repeated vomiting of dark coffee-ground looking fluid. I gave another enema, and applied more leeches. In spite of treatment, she gradually got worse, and died on November 16th, four days after confinement.

This last case was one of decided puerperal peritonitis, without those marked symptoms of fever which existed in the case of the woman Garton. During life, there was a moisture upon the skin; and there was no dryness of the tongue until the last few hours. The bowels acted of themselves after about four injections had been given; but the pain was never absent, and the pulse sometimes 200 in the minute. I had at one time, from the action of the bowels, and the skin, some hopes of this woman's recovery; but to no remedy did the pain yield. Besides the calomel and opium every three hours, I at times gave full doses of the latter, with a view of allaying the irritability, and, if possible, of relieving the extreme pain. Leeches appeared to afford little or no relief. The vomiting was almost incessant.

After the death of this woman, so convinced was I that I carried about with me the poison which was working such frightful consequences, that I destroyed my clothes, sponged myself all over with a solution of chloride of lime, and rode for miles about the country, exposed to all weathers, hoping that the storm and wind might help to purify me from this fearful scourge. Luckily for myself and my patients, I had no other case of midwifery for more than a week. I took every precaution to interfere as little as possible, and was gratified by the recovery of the woman without one unfavourable symptom.

REMARKS. In the first case, the woman Freshney, having gone through (if I may so express it) the dangerous stage of erysipelas, had a premature labour, unattended by any bad symptoms, from which she speedily recovered.

In the second case, that of Mrs. Buchan, I think it may very fairly be asked, whether she did not in great measure owe her recovery to the inflammation attacking the mucous membrane of the bowels, instead of the peritoneum? the diarrhoea which she had previously to her confinement, as well as at the time, showing an irritable state of that membrane. In this case, both the attendants had inflammation of the absorbents, and abscesses, with considerable febrile derangement; the inflammation being of an erysipelatous character.

In the third case, that of Mrs. Garton, death took place so rapidly, from the extreme violence of the symptoms, as

to leave scarcely any time for medical treatment to be of any avail; and in this case the nurse died of erysipelas.

These facts appear to me to confirm the doctrine, that so-called puerperal fever or peritonitis is a disease of an erysipelatous character; and that it is capable, under certain circumstances, of infecting other persons with erysipelas, which may even prove fatal.

In connexion with this subject, I will quote the following interesting observations from a Report of the Standing Committee for the Western District of New Jersey Medical Society, by Dr. Parrish:—

"The simultaneous occurrence of erysipelas and puerperal peritonitis has often been a subject of useful and interesting inquiry among physicians. As evidence of there being great danger of communicating to parturient females the contagious virus of erysipelas, it may be stated that, while recently visiting a patient with this disease, and engaged in making applications to the inflamed part, the writer was called to wait upon a female in labour. Under the apprehension that there might be some danger of communicating the disease, the examinations *per vaginam* were as few and as rapid as circumstances would justify; but the case being very tedious, and requiring the employment of forceps, the hands were necessarily brought into contact with the mucous membrane of the vagina; and, though they had been thoroughly washed, the patient barely escaped with her life, from an attack of puerperal fever, with an offensive discharge from the uterus, and an acrid secretion from the vaginal walls. The infant, at the age of about two weeks, was seized with a severe attack of erysipelas, invading the head and shoulders, and extending down the back. The integument became extremely indurated; the skin assumed a dark, livid hue; and the little sufferer died on the third day, in a state of coma. A similar case occurred not long since, in the practice of another member of your committee; and the infant died with erysipelas about the nates, between the third and fourth week." (*London Journal of Medicine*, January, 1850, p. 57.)

Moulton, near Spalding, Lincolnshire, February 1853.

CASE OF HEMIPLEGIA FROM EXPOSURE TO SOLAR HEAT.

By WILLIAM HENRY ASHLEY, M.D., Surgeon to the Kensington Dispensary.

THE months of July and August of the past year were remarkable for a temperature unusually high for this climate, ranging in the shade at noon from 80° to 90° Fah., with probably an increase of 15° or 20° in the sun. The effects of this intensity of heat on our labouring out-door population were most baneful; and among the number of those who succumbed to its influence, may be mentioned the following instance.

CASE. James Bond, aged 24, a brickmaker's labourer, came under my care as a dispensary patient on August 3rd, 1852. He was of spare habit, had lived temperately, and enjoyed good health up to the time of the attack. During the sultry weather he had been engaged in conveying unburnt bricks to the kiln. The high solar temperature (blood-heat) to which he had been exposed, was rendered more aggravating by the burning brick-kilns; and under these adverse circumstances he had complained from time to time of much distress, and of headache. I did not see him until some hours after the attack. His statement was then very rambling, and his language incoherent; I gleaned, however, from him, with much difficulty, that he had no recollection of what had transpired from the time he quitted the brick-field, until he found himself in bed (his room was within a short distance of the field in which he had been employed), and he believed that the attack was not instantaneous. No person was present who could give any further account of his illness.

The pulse was small and 52 in the minute; the respiration natural; the complexion neither flushed nor pale.

head unduly hot; the eyes had a wild expression; the pupils contracted imperfectly under the influence of light; the conjunctivæ were not suffused; the tongue was drawn to the left side, and protruded with difficulty; it had a white fur, and was moist. His articulation was very much impaired; so much so that it was scarcely possible to comprehend one word that he attempted to utter; the mind also appeared somewhat imbecile. He had not felt pain in the head since the attack. There was complete deprivation of voluntary power over the right half of the body; the facial muscles were drawn to the left side; sensation was perfect, and the temperature uniform throughout. The functions of the involuntary muscles were unimpaired; there was no retention of urine nor constipation of the bowels. The nurse had not observed any muscular twitching or convulsive movement, nor had there been any delirium.

The following medicine was ordered: *R. Hydrargyri chloridi gr. vj; olei tiglii gr. i*: to be taken immediately, and followed in an hour by a turpentine enema. The head was to be kept raised on a pillow, the hair removed, and iced lotion to be occasionally applied to the scalp. The hot mustard hip-bath was directed to be used as soon as possible. Twelve leeches were applied to the temples. *R. Hydrargyri chloridi gr. ij; pulv. cinnamomi compos. gr. viij. M. Quartis horis sumatur.* The patient was ordered to take barley-water and gruel as nourishment.

August 5th. The pulse had increased in frequency. There was no anæsthesia nor formication; articulation was a little more distinct; he had no pain or throbbing of the head, nor intolerance of light, or excessive sensibility to sound. The bowels were relaxed, and the urine was copious. *Acetum cantharidis* was ordered to be applied to the scalp on the left side, and the blistered surface to be kept open with an ointment, formed of equal parts of the *unguentum hydrargyri*, *unguentum iodinii compositum*, and *unguentum cantharidis*, combined with one third portion of lard. The following powder was ordered to be taken every six hours: *R. Hydrargyri cum cretà gr. ij; pulv. cinnamomi compos. gr. v; and beef-tea*, as sustenance.

August 7th. The pulse was 70 in the minute, with increased power. He pronounced words with less difficulty; voluntary power was returning; the right foot could now be moved, and the facial muscles were but slightly distorted. The *hydrargyrum cum cretà* and *pulv. cinnamomi compos.* prescribed at the date of the last report, was now ordered to be taken three times a day; and the beef-tea and gruel to be continued.

August 13th. He had continued to improve daily. The paralytic condition had left but a trace of weakness on the right side; the voluntary power of the arm was restored, but the leg was still feeble. Articulation was scarcely affected; the muscles of the face had assumed their normal appearance. The following medicine was prescribed: *R. Hydrargyri cum cretà gr. ij; extracti hyoscyami gr. iij. M. Ft. pilula mane nocteque sumenda. R. Potassii iodidi gr. ij; ammoniæ sesquicarbon. gr. v; misturæ gentianæ compos. ʒj. M. Fiat haustus ter quotidie sumendus.*

From this date he might be considered convalescent; and in three weeks the power of locomotion was perfectly restored, and his health reinstated.

REMARKS. The majority of those who fall under the malignant influence of *coup de soleil* never rally; death too frequently ensuing either from apoplexy or shock. In this case, although the patient escaped the more fatal consequences, hemiplegia was the result.

In a remote age, we find the father of medical science thus briefly alluding to this subject:—"And when they pass their fiftieth year, defluxions supervening from the brain render them paralytic when exposed suddenly to strokes of the sun or to cold." Here, however, the paralysis was not a sudden result of the stroke of the sun; nor did it arise from apoplectic seizure, or transient vascular distension; for it did not appear until some hours had elapsed after the exposure, and not until all evidence of determination of blood to the brain had ceased. The pathological

condition will be better explained, by attributing it to serous effusion consequent on congestion of the cerebral vessels.

In the earliest stage, that of local hyperamia with determination of blood to the brain, the cold douche to the head, hot mustard pediluvia, and topical blood-letting, should promptly be had recourse to, together with the remedial measures before mentioned as having been employed in the case described. Should there, however, be any tendency to collapse, much circumspection will be required in order that we may not depress the vital powers; it may, indeed, be necessary to support with ammonia, ether, and other stimulants.

Excepting where apoplexy supervenes, general blood-letting, as a rule, is not admissible. We read that very doubtful benefit, if not positive injury, has resulted from it; the pulse has been observed to fall very rapidly, and the heart's action to become embarrassed, threatening syncope. Another grave objection which may also be advanced against the use of the lancet in these cases is, that by abstracting the more solid constituents of the blood, and thus diluting it and impairing its vitality, the risk of serous effusion is much increased.

In the more advanced period, that of effusion, the ointment before cited is most useful as a counterirritant in promoting the removal of the morbid product. The exhibition of mercury, however, in small and repeated doses, is mainly to be relied on, as it not only arrests the effusion, but conduces to the absorption of serum and coagulable lymph. Moreover, mercury should be administered at the earliest period of the attack as a preventive of inflammation; indeed, this is a most important indication in the treatment, not only of this affection, but in all cases where we have reason to believe that inflammation may be impending. By judiciously introducing into the system this invaluable agent, local inflammatory action may be prevented, or certainly arrested, before the more tangible symptoms reveal themselves to our senses; we thus anticipate the evil, and take measures to prevent its advent.

8, Boyne Terrace, Kensington Park,
February 8th, 1853.

CASE OF STRICTURE OF THE ŒSOPHAGUS.

By GEORGE LOWTHER, M.R.C.S.

THE following case of œsophageal disease, which occurred in my practice several years ago, I have been led to submit to the notice of my professional brethren, mainly from the fact that it resisted all remedial measures, even in the hands of men of eminence and extensive practical experience; and under the hope that this failure may prompt us to renewed exertions, in order to devise, if possible, some method of cure for one of the most formidable and distressing maladies incident to humanity.

CASE. Near the close of the year 1844, Mr. S., a corn merchant, felt, for the first time, an obstruction during deglutition, immediately above the sternum. Three months subsequently, the dysphagia increasing, he grew anxious, and consulted me on his complaint. I put him under a course of antispasmodics, alteratives, and counterirritants, with occasional aperients, and lastly mineral tonics; and at the end of three weeks, the difficulty of deglutition was decidedly relieved. The relief, however, was but temporary. He next took the advice of Dr. A—, then resident in Hull. Early in April, he left home, with the intention of consulting some metropolitan physician.

After an absence of three months in London, having been attended by Dr. C., afterwards by Dr. W., and finally by Mr. A., he returned home, greatly emaciated, and in no way benefited.* Dr. C. prescribed antispasmodics and mineral tonics; Dr. W. administered mercury, to moderate

* Mr. S. had in addition, during his stay in London, the advice and assistance of Mr. V., a surgeon of considerable practical experience.

ptyalism; and Mr. A. excluded medicine altogether, and confined his treatment to the introduction of an elastic gum catheter into the œsophagus two or three times a week.

On June 29th, the day after his return, I saw him. He had shrunk considerably; his step faltered; and his countenance indicated great anxiety. There were cough, dyspnoea, and hoarseness, which he attributed to a cold, caught a few days before, on a foggy day, in the suburbs of London; but which symptoms denoted, in fact, an extension of the disease, by proximity, from the œsophagus to the larynx.

June 30th. I witnessed an attempt to swallow a little milk. The effort caused an immediate distension, or bulging, just above the sternum, approximating in form and size to a small orange. The dysphagia appeared very distressing. After several ineffectual attempts to force the milk through the stricture, it was at length regurgitated, a small portion having passed, apparently *guttatim*. A glass, containing half a pint of milk, stood by him; he took an ounce at once, and regurgitated each successive draught, until the glass was empty. The fluid was then measured, and it was found that from half an ounce to an ounce had passed into the stomach. The introduction of a flexible catheter was arrested just behind the clavicular end of the sternum; by a slight manipulation, however, it passed its full length, eleven inches. The operation was repeated on July 2nd, also on the 4th, 6th, 9th, 12th, 14th, and 16th, with little amelioration in the dysphagia.

July 17th. The dysphagia was increased. Vesication over the trachea was ordered.

July 18th. I introduced the bougie, and ordered a few minims of an antispasmodic tincture to be given in mucilage occasionally; and an anodyne liniment to be applied over the blistered surface.

July 20th. The bougie was now introduced morning and evening. I ordered an antispasmodic and diffusible stimulant, containing half a grain of strychnia. The vesication was repeated; and oil of turpentine was applied over the blistered surface.

July 21st to 28th. The same treatment was continued, with the addition of an expectorant mixture. On the last named days, the patient was ordered to inhale occasionally the steam of half a pint of boiling water, with which two drachms of extractum conii had been mixed.

July 29th. He had slight pyrexia, and was ordered to take a sedative julep every three hours.

July 30th. I introduced the bougie. Ten minims of nitric acid were ordered to be taken three times a day, in a wineglassful of decoction of sarsaparilla, and soap liniment, with equal parts of tincture of iodine and spirits of turpentine, to be applied over the trachea.

August 1st. The plan of treatment hitherto described had had no effect in arresting, scarcely in mitigating, the morbid action in the larynx or œsophagus. His dyspnoea increased, and the larynx was acquiring a croup-like sound during inspiration. Emaciation and debility increased rapidly. The countenance had become anxious and cadaverous. Life had been chiefly supported since his return by beef-tea and other nutritious injections.

August 3rd. He was so much worse this morning, that I declined introducing the bougie. In the afternoon, I was hastily sent for. His breathing had become painful and laboured. Shortly after my arrival, he was seized with spasm of the glottis. He gasped for breath, implored the bystanders to give him air, and anxiously inquired if he was dying. The spasm gradually subsided, but was succeeded, at short intervals, by a second and a third attack, each paroxysm being less severe than the former. Dr. S., who had been a few days in attendance, directed a combination of opium, calomel and tartar emetic, to be administered every four hours. Leeches were applied over the os hyoides; vesication over the trachea; and the nitrate of silver in solution to the pharynx and epiglottis. Preparations were also made for tracheotomy, in the event of a recurrence of spasm.

August 4th. He passed a tranquil night. The antispasmodic powders were continued.

August 5th. It would be superfluous to particularize the remaining treatment. Anodynes, antispasmodics, and counterirritants, appeared to arrest further spasmodic action. The patient, however, gradually grew worse. Having lingered until the 8th, after having been insensible for half an hour, he expired.

Section Cadaveris, twenty hours after death. The œsophagus having been reflected from its vertebral attachments, together with the larynx, the latter was first opened.

The entire mucous membrane, particularly about the rima glottidis, was so much thickened, as to lessen considerably the diameter of the larynx. It was covered with a thick, glutinous, chocolate-coloured coating, but had no perceptible evidences of ulceration. These appearances extended in a less degree to the trachea, and were lost in the bronchi.

The œsophagus was then examined. On tracing it downwards, the canal began gradually to expand, until it had acquired an extraordinary calibre, presenting a pouch-like appearance, which at once accounted for the bulging during deglutition. Immediately opposite the clavicular extremity of the sternum, the canal had become thickened, indurated, and contracted. Here, of course, was the seat of stricture. The diameter of the tube was so diminished, as scarcely to admit the bougie (a tapering one) to be drawn through it. The cellular tissue connecting the larynx and œsophagus was entirely obliterated; and the two tubes were so completely connected, as to render their separation impossible. A full-sized œsophageal bougie, introduced into the canal immediately below the stricture, passed, with a slight sensation of obstruction, into the stomach. The remainder of the canal, however, was quite normal, the obstruction being occasioned by an osseous growth projecting from one of the dorsal vertebrae.

There was nothing remarkable in the thoracic and abdominal viscera, beyond a diminution in size, and a general appearance of exsanguinity. The stomach, as might be anticipated, had shrunk considerably. The head was not opened.

A practical writer has lately said, "Whoever abuses the functions of an organ, accepts a blank bill upon the future. It may run for a longer or a shorter date, but it *must* come due." Alas! bills, wherein Disease is the witness, and Death the acceptor, belong to an old currency of a world-wide circulation. That they are frequently self-drawn, is proved by sad experience; the present case affording a painful illustration. Mr. S., although rarely intoxicated, had been in the daily practice, during several years, of indulging in strong spirituous potations. He was, moreover, a free smoker. That the structural change in the œsophagus had been induced by the artificial habits he had acquired, admits not, I think, of the slightest doubt. The disease was not malignant; and in this view Dr. S. coincided. The case is one of those wherein we discover the futility and utter inefficiency of all remedial agents, in controlling or modifying severe structural changes, or extensive organic lesions.

3, Nelson Street, Hull, February 14th, 1853.

ABSCESS OF THE CÆCUM, CONTAINING SOLID OPIUM, IN AN OPIUM-EATER.

By J. P. BOWLING, H.E.I.C. Bengal Medical Establishment.

CASE. Charles E. May, aged 25, a sergeant in H.M. 51st regiment, was admitted into hospital under my care on the 29th of June 1852. He complained of having been feverish and unwell for some days, with occasional fits of shivering followed by heat of skin and sweating. He had also a dull aching pain, and slight tenderness in the right iliac region, with thirst and foul tongue. The bowels were constipated.

the pulse was 90, and weak. He was ordered to have a dozen leeches applied, followed by warm fomentations to the seat of pain, and to take a mercurial purgative.

June 30th. He stated that the leeches had considerably relieved the pain: but he still felt uneasiness on pressure. The purgative had acted well, and had brought away a large quantity of dark offensive faecal matter. The tongue was clean; the skin cool and moist; the thirst less; pulse 100, and weak; he had had no rigor since admission. He was now ordered bark with sedatives, with generous diet, and a small quantity of wine. Under this plan of treatment, he appeared for a few days to be improving.

July 6th. He had been observed for the last day or two to present a dull heavy look. He appeared quite apathetic and indifferent to all around him, sleeping a great deal, and in fact exhibiting all the appearance of a man under the influence of opium. When questioned on the subject, he strenuously denied ever having taken a grain of that drug beyond what had been prescribed for him.

He continued in the same state of drowsiness and oppression, which masked any symptoms which might otherwise have presented themselves, and making no complaint beyond that of debility and want of appetite,—the pulse becoming weaker and more rapid, till the morning of the 13th, when he expired.

On removing the body, nearly two ounces of opium were found beneath the bedding. His comrades admitted that he had been in the habit of taking large quantities for the last seven years.

Post Mortem Appearances. The body was well formed, but attenuated. The contents of the thorax were healthy. In the abdomen, the cæcum was found distended, and formed the pouch of an abscess, which contained about four ounces of highly offensive pus. Throughout this collection of matter were seen seven or eight pieces of a dark looking substance, which, on being submitted to examination, proved to be opium. Their weights varied from one to three grains each. There were traces of recent peritonitis, but not of an active character. Owing to the absence of proper instruments, the head could not be examined.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

IODIDE OF SODIUM IN THE TREATMENT OF CONSTITUTIONAL SYPHILIS.

DR. UBALDO DAVERI, Chief Physician of the Hospital of Saint Orsola in Bologna, has employed the iodide of sodium instead of the corresponding salt of potassium. The iodide of sodium employed by Dr. Daveri, was prepared by placing three ounces of filings of iron in two and a half pounds of distilled water, and gradually adding, with constant agitation, a pound of iodine; as soon as the mixture had acquired a greenish colour, it was filtered and quickly treated with a solution of carbonate of soda, until all the iron was thrown down. The carbonate of iron thus formed was separated by filtration, the filtered fluid evaporated to dryness, and the residuum again dissolved, filtered, and evaporated, until a pellicle had formed. By this method, fourteen ounces of iodide of sodium were procured in the form of white rhomboidal prisms, deliquescent, and having a saltish taste, less disagreeable than that of iodide of potassium.

The iodide made from iodine and caustic soda is disagreeable to the taste, gives rise to a burning sensation in the fauces, to weight and uneasiness in the stomach, and to gastro-enteric pains.

The dose administered at the commencement of the treatment, was always a scruple of the iodide dissolved in three ounces of distilled water, and given in three equal portions in the course of twenty-four hours. The salt was likewise employed, in the form of ointment, in the proportion of half a drachm or a drachm to the ounce of lard. In the administration of the iodide of sodium, the same rules and precautions are to be observed as apply to the use of the potassium salt. The author divides the 110 cases, on the observation and treatment of which his paper is based, into the three following classes:—

1. Cases of constitutional syphilis, in which so-called secondary and tertiary phenomena co-existed.

2. Cases of so called tertiary lues, in which the use of mercury preceded the treatment by iodide of sodium.

3. Cases of so-called tertiary lues, in which iodide of sodium alone was employed.

Of the first class, twelve cases, in which the symptoms were pains in the bones or periostitis, united with some manifestly constitutional affection of the skin, generally of a papular or pustular form, were treated with iodide of sodium. In eight of these cases, the use of the salt alone effected a cure; in the remaining four, it was necessary to have recourse to mercurial frictions, to remove the cutaneous affection which remained after the tertiary symptom had yielded to the iodide. The minimum quantity which succeeded in curing the disease was three drachms, the maximum three ounces; the quantity which was usually required ranged from two to three ounces. The shortest time in which the symptoms were removed was nine days; the longest, three months; the average was about a month.

The cases of the second class, or those of so-called tertiary lues, in which the use of mercury preceded the treatment by iodide of sodium, were seventeen. In some of these, six or seven ounces of stronger mercurial ointment had been rubbed in; the average quantity was from four to five ounces. The minimum quantity of iodide of sodium administered was three drachms; the maximum, four and a half ounces; the average, from one to two ounces. Those patients who had derived no benefit from a protracted course of mercurial treatment, were cured after the administration of a small quantity of iodide of sodium; while this remedy had to be given to the extent of four and a half ounces, in cases in which only a limited number of mercurial frictions had been used. The patients who resisted the long continued employment of the ointment, laboured under osteocopic pains, which subsequently gave way to a small quantity of the iodide; while those who practised, without benefit, a moderate number of mercurial frictions, suffered either from syphilitic rheumatism, or from a mixture of syphilis and scrofula. This fact of the iodide being required in the inverse ratio of the amount of mercury previously employed, arises, the author thinks, from this,—that in the first case the use of mercury had, in a great measure, overcome the syphilitic element, which was then entirely removed by the administration of the iodide; while in the second the elimination of the constitutional venereal principle, commenced by the mercury, was, for the most part, reserved for the iodide of sodium.

The cases belonging to the third class, comprising those of so-called tertiary lues, in which the iodide of sodium was the only medicine administered, were eighty-five in number; of these, thirty-seven were cases of ostalgia, in the treatment of which vapour baths and iodide of sodium were employed: the minimum quantity of the latter given was from one to seven drachms; the maximum, from eight to twelve ounces; the average, from two to four ounces. Of rheumatism, the cases were seventeen, likewise treated with vapour baths and the iodide; the minimum dose of the latter being from two to four drachms; the maximum, nine ounces; the average, two to four ounces. Of arthralgia, nine cases were similarly treated; the minimum quantity employed having been seven drachms; the maximum, two ounces. Of the other varieties of tertiary disease, the numbers were too limited to require special mention, or to justify the deduction of conclusions from them.

Derangement of the stomach, iodic eructations, pyalism, and affections of the throat, were seldom met with from the time the iodide of sodium was substituted for the potassium salt; consequently, the remedy could be more steadily persevered with, and its dose more rapidly increased: circumstances directly promoting the cure of the diseases for which it was administered. In the few cases in which pyalism occurred, it totally ceased on suspending the medicine for two or three days. In but a single case, did it appear to be obstinate; and in this instance the mouth was, on examination, found to be pale, free from swelling, and very slightly painful. As the patient lay in a ward with many syphilitic patients under mercurial treatment, it was thought the salivation might be owing to mercurial vapour present in the atmosphere—a suspicion which was verified by the result; for on removing the patient to another apartment, free from mercurial contamination, the salivation entirely ceased in two days.

The time required for the cure of nineteen patients treated with the iodide of sodium, was about twenty-eight or twenty-nine days; while with the potassium salt, likewise exhibited in nineteen cases, the average time was from thirty-four to thirty-

five days. Many cases, which had either not got entirely well, or were proceeding but slowly, under the use of the iodide of potassium, were rapidly cured by the substitution of the corresponding salt of sodium.

Several of the cases, however, treated with iodide of sodium, relapsed, and the disease again yielded sometimes to a repetition of the remedy, sometimes to the use of mercurial frictions. But this circumstance cannot be urged against the iodide of sodium alone; for the same is equally true of every other antivenereal remedy,—one of the leading features of lues being its tendency to present periods of lull and of relapse, whatever be the therapeutic means employed.

The author concludes his paper with the following *résumé* :—

1. Soda being a very common ingredient in our organism, the iodide of its base appears best suited to the human system.
2. The taste of the iodide of sodium is much less disagreeable than that of the iodide of potassium.
3. It is less likely to occasion iodism.
4. It is better borne than the potassium salt, and in consequence of this, its dose can be almost daily increased; and it thus becomes a more efficient remedy.
5. It has sometimes succeeded where the iodide of potassium had failed.

6. We may commence by giving daily, in three equal doses, a scruple of the salt dissolved in three ounces of distilled water, increasing the strength of the solution, every two or three days, by six grains. Some patients have, in this way, been able to take more than two drachms a day, without suffering the slightest inconvenience.

7. The iodide of sodium is admirably adapted to cases in which the corresponding salt of potassium is indicated.

8. The iodide of sodium is the best substitute for mercury.

(Abridged from *The Chemist*, December, 1852, as quoted from *Corrispondenza Scientifica di Roma*, No. 32, 1852.)

CASES OF LYMPHORRHAGIA: VARICOSE DILATATION OF THE LYMPHATIC VESSELS.

In the *Mémoires de la Société de Chirurgie de Paris*, tome iii, fascicule 2, M. DEMARQUAY has published two cases of lymphorrhagia, or escape of lymph from the external surface of the body.

CASE I. M. X., aged 17, on the 9th of March, 1852, while playing with some relatives, accidentally found that his shirt and trousers were wet. On examination, he found that the fluid escaped from a part of the thigh; it was at first colourless, but soon became milky. A medical man was called, who arrested the flow by applying a compress dipped in cold water, with a slightly tightened bandage. The next day M. Demarquay found, at the lower and inner part of the left thigh, numerous small depressible elevations, which he at first took for hypertrophy of the follicles. The linen, which had been worn on the previous day, had become stiff, as if it had been dipped in an albuminous fluid. It was evident that much lymph had escaped; but the exact point of its exit could not be determined.

Some days afterwards, M. Demarquay had an opportunity of seeing some lymph escape from the lower and inner part of the right thigh of M. X. It was at first colourless, and of a slightly opaque tint, passing to yellowish white on accumulation in a glass vessel. On examining with a lens, M. Demarquay ascertained that it escaped from a very limited spot: it was thrown out with some force, for it slightly raised the epidermis; indeed, it flowed in the same way as blood from a small arterial twig at the bottom of a wound. Eight *grammes* (a little more than two drachms) were collected in a wine glass: in a few minutes the fluid was entirely coagulated; it adhered to the vessel, and presented a bluish white appearance, inclining to yellow.

Some days afterwards, MM. Denonvilliers, Ricord, and Flourens examined the case with M. Demarquay. Independently of a series of granular elevations at the inner part of the right thigh, at the union of the lower with the middle third, there was a projection three or four *centimètres* (one inch and one-fifth to one inch and a half) in extent, reaching, in a slightly curved form, from the front to the inner part of the thigh. It yielded to pressure like a varicose vein; upon and around it were small granular elevations. The projection increased on motion, and diminished during rest; it was evidently a varicose dilatation of a lymphatic vessel.

From this time till September, M. X. remained free from the lymphorrhagia. At the latter period, when in Montpellier, he was again attacked; the fluid was then examined by M. Bouisson and other physicians. A flow of lymph occurred for a short time on October 31st; and on November 1st it returned, and continued during nine hours, in spite of pressure by means of a handkerchief, which had hitherto been found sufficient to arrest

it. M. Demarquay obtained several ounces of fluid, some of which was furnished to M. Mialhe for chemical examination. The fluid coagulated, like that already described: but a clot was soon formed in the centre, appearing as if composed of a series of reddish filaments in abundant serum. The varix had increased in size, and the granular elevations observed in March had become transparent and vesicular. On pricking one of them, lymph escaped. The right thigh was at this point more than two *centimètres* (four-fifths of an inch) larger than the left.

Pressure above and below the point whence the lymph escaped gave rise to a jet as from a vein of moderate size. When pressure was made below the dilatation, the flow was not arrested.

M. Demarquay observes that there was here not only dilatation of a lymphatic vessel, but also of the superficial network at two points of the thigh; viz., anteriorly and interiorly at the junction of the lower with the middle third, and on the anterior part at the middle third. The escape of lymph during nine hours did not produce inconvenience; and, up to the date of the report, the disease had continued, and the flow of lymph had gradually increased.

CASE II. This case was observed by Dr. Fitzer. A young lady, aged 16, who had not menstruated, had had crural hernia from the age of eight years. In 1847, she found that she had on her abdomen a number of small granular elevations; she was examined by Dr. Fitzer, who found a brownish stripe three finger-breadths in width, commencing an inch below the umbilicus, to the left of the linea alba. It extended to the left and upwards, passing between the false ribs and the ilium, and ended at the dorsal vertebra, becoming smaller and more transparent at this part. The middle part of this streak was prominent, and was formed of about eighteen papillary enlargements; some of these resembled the mammillary papille in men, others those in women; they were not tender to the touch, and disappeared on pressure. In July, the patient felt some pain in the situation of the streak; and on the 31st of that month, after returning from a walk, she found that there was escaping a milky coagulable fluid. She estimated the quantity which escaped at a quarter of a pint. Dr. Fitzer found the appearance of the parts the same as before. The fluid continued to escape during three days. It was milky, of a saline taste, alkaline, and escaped from two of the largest of the elevations which have been described. When one orifice was compressed, more lymph flowed from the other. Dr. Fitzer cut one of the elevations with curved scissors; he was able to pass a probe for an inch right and left: a quantity of lymph escaped from this incision. Pressure, and the application of alum, were insufficient to restrain the flow of lymph; Dr. Fitzer therefore applied nitrate of silver. It was important to arrest the disease, as the girl was losing strength, and the pulse was becoming weak. The lymphorrhagia ceased, but the granular projections remained; new ones were even formed, of the size of a lentil or millet-seed, while the skin over the remaining part of the streak had become pale, like that of the rest of the abdomen.

Microscopical and chemical analysis of the fluid, made by M. Schlossberger, left no doubt that it was lymph.

M. Demarquay has not been able, after diligent search, to find any records of cases of lymphorrhagia from spontaneous rupture of the vessels: cases of lymphorrhagia from wounds have been recorded by Nuck, Van Swieten, and Assalini.

Dilatation of the lymphatic vessels has been observed by Baillie, Mascagni, Amussat, Breschet, Sir A. Cooper, Bichat, Sömmering, Morgagni, Beau, Ricord; also by Bidloo, Meckel, Rokitansky, Albers, Andral, Otto, and Hasse.* But the facts have not as yet been sufficient to enable pathologists to determine the causes, forms, varieties, diagnosis, prognosis, or treatment of the disease. As far as M. Demarquay knows, M. Beau is the only surgeon who has attended to the treatment. In cases of dilatation of the lymphatics of the prepuce, he introduces a small seton into the dilated vessel, and removes it at the end of three or four hours. Obliterative inflammation is thus produced.

EPIDEMIOLOGY, HYGIENICS, AND STATISTICS.

SMALL-POX.

THE epidemic small-pox which visited England in the early part of the year 1852, was at least as severe in its character, as malignant in its contagious tendency, and as fatal to its victims, as any variolous epidemic with which this country has ever been visited. The visitation commenced in the last quarter

* Hasse's *Pathological Anatomy*. Sydenham Society's Translation.

of 1851, advanced rapidly until the termination of the year, and continued its fatal career till the end of July 1852, when it began to decline with steady rapidity till December, during which month there were only 14 deaths; the monthly average during the last twelve years being 74. The following table is constructed from the weekly reports of the Registrar-General as regards the mortality from small-pox in the metropolitan districts:—

DEATHS FROM SMALL-POX.

From 1840 to 1851, the average deaths from small-pox were about	801 per annum.
In the last quarter of 1851 there were 339 deaths; rate,	1356 "
In the first quarter of 1852, 389 deaths; rate,	1556 "
In the second quarter of 1852, 472 deaths; rate,	1888 "
In the third quarter of 1852, 221 deaths; rate,	884 "
In the fourth quarter of 1852, 74 deaths; rate,	296 "

The present average is, therefore, four times less than the average of the preceding eleven years. The disease has, however, broken out with great severity in South Wales, where an epidemic of very fatal character has been raging, particularly in the iron districts, for the last three months. It has likewise been very fatal in the West of England, especially at Bristol, where it has assumed a peculiar and somewhat novel character; the type being malignant and confluent, and the pustules running into putrid masses with unwonted rapidity. Mr. Stansbury is of opinion that the disease is of Irish introduction, as the first case which came under his notice he could trace directly from Ireland.

Small-pox is essentially a pustular affection; and it is remarkable that it should have immediately succeeded the prevalence of the furunculoid epidemic. The deaths from carbuncle attained their greatest number in the first quarter of 1852, in which there were 16 deaths from that disease, or a rate of 64 per annum, the average being 44; and the deaths from small-pox in the second quarter of 1852 were 472, the rate being 1888 per annum; the average being about 792. It becomes a question of interest, therefore, whether a general tendency to pustular formations may not have had some common influence in producing both epidemics. During the year 1852, there were more cases admitted into the small-pox hospital than in any former period since its original establishment; and the fatality has been equally extraordinary. The corymbose and hemorrhagic forms of the disease, both of them at all times almost uniformly fatal, have prominently marked its course. It is also worthy of remark, that, almost immediately preceding its outbreak in Europe, the Indian Presidency of Bengal was visited with one of those awful variolous epidemics which have devastated that "city of palaces" on several occasions during the last half century. The visitation of 1840-50 was so fatal in Calcutta, that, notwithstanding the proverbial apathy of the inhabitants (who have, as a body, rejected the protection of vaccination), yet, on this occasion, a general panic of so unusual an order seized on the inhabitants, that government appointed a special commission to inquire into the nature of the epidemic. The report of these commissioners has been transmitted to the Epidemiological Society; and it appears that, during the years 1840-50, among the native inhabitants, the deaths from small-pox actually amounted to 4,467, the total deaths from all diseases being 9,530: in other words, the deaths from small-pox alone were 46·86 in 100 deaths. In the following year, the disease visited Europe; thus travelling, like the cholera, from east to west.

SCARLATINA.

The more common epidemics have been observed, from time immemorial, to follow hard upon each other's footsteps. It has been shown, that the late variolous epidemic attained its height in the metropolitan districts in the second quarter of 1852; that it declined in the third quarter of that year; and in the fourth quarter diminished to an amount far below its average. Now, by comparing the following tables, it will be seen that, no sooner had small-pox begun to decline, than another epidemic, scarlatina, began to manifest itself; and observed a rapidity in its advance remarkably proportioned to the rapidity of the decline of small-pox.

SMALL-POX. Annual average, 840.	1852.	SCARLATINA. Annual average, 1794.	1852.
1st quarter, deaths	389	1st quarter, deaths	366
2nd quarter, "	472	2nd quarter, "	563
3rd quarter, "	221	3rd quarter, "	668
4th quarter, "	74	4th quarter, "	952
1st six months, .	861	1st six months, .	920
2nd six months, .	295	2nd six months, .	1,620
Total deaths in 1852,	1,156	Total deaths in 1852,	2,549

Thus it appears that, while both of these epidemics exceeded their usual average in the year 1852 by about one-third, the actual excess in small-pox was observable in the first six months only; while the excess in scarlatina occurred in the second six months only; and that the excess of each, in its own epidemic half of the year, was about double the average half-yearly number; the small-pox cases being rather more than double, the scarlatina cases rather less than double, the average of six months.

It can scarcely be doubted that, amidst the general darkness and mystery in which the causes of epidemics are involved, a ray of light might be struck out, if, with the aid of general registration, the future history of different epidemics, especially with regard to their relative rise, progress, and decline, could thus be accurately traced and systematically recorded. We doubt not that the zealous members of the Epidemiological Society will ultimately have their attention drawn to these interesting points. Meanwhile, we earnestly call upon the members of our Association to avail themselves of their local opportunities, each in his own sphere, of noting, recording, and tabulating, corresponding facts.

In the preceding sketch of the epidemics of 1852, as regards the metropolitan districts, we have purposely abstained from all reference to the influence of vaccination in protecting the population against small-pox, because we are looking with eager expectation to the forthcoming report of the Small-pox and Vaccination Committee of the Epidemiological Society, which, we trust, will set most of the vexed questions connected with vaccination at rest. But, lest the late variolous visitation should lead any of our readers to erroneous conclusions as to the general failure of Jenner's discovery, in its protective power over the population at large, we can only entreat them to wait until the whole subject has been brought before them in all its details, and in its momentous bearings upon the prospects of this country and the world at large, in regard to the possibility of being better prepared to meet any future outbreak of this terrible disease.

There is one interesting fact disclosed in the quarterly return just published by the Registrar-General, viz., that, while the metropolitan mortality has been considerably below the average, as likewise the mortality in the provincial towns, the mortality of the provinces generally was above the average. This may be accounted for, if we reflect that a very rainy season, while it will augment the general tendency to disease, will also, by washing out the drains of large cities, tend to diminish the rate of mortality arising at all seasons from this very fruitful source of disease and death. It is also reasonable to attribute the superior salubrity of the town districts to the energy with which, in some localities, the new Sanatory Act has been enforced under the direction of the Board of Health.

MEASLES.

This disease is at present very prevalent in London and some of the suburbs. The epidemic is of a mild character; but from the severity of the season, the children of the poor frequently have a tedious and imperfect convalescence. The eruption is in general very profuse, and the fever slight.

FURUNCULOID EPIDEMIC: APPEARANCE OF ACUTE PEMPHIGUS.

The epidemic of carbuncles is still raging in London, and has been more fatal during the last month than at any previous period, except in the month of September last year, in which were registered 10 deaths. In January 1853, 9 deaths were registered, three of which occurred in the last week of the month. In one of these, the patient, a lady of 39, survived with a succession of carbuncles for five months, during the last five weeks of which they became complicated with whitlows and abscesses, under which she sank. In several instances, the disease has of late commenced with vesications; and it is also remarkable, that two or more deaths have recently occurred from pemphigus, which, in its acute form, is extremely rare in

this country. In its malignant form it is a horrible disease, more dangerous than small-pox, and quite as repulsive and distressing. The type is low, and the serum in the vesicles speedily assumes a putrid condition, and exhibits a dark colour. The pulse is frequent and feeble, and the mucous membranes often participate in the disease, and discharge an offensive muco-purulent fluid.

SURGERY.

RHINOPLASTIC OPERATION: FLAPS FORMED BY SUBCUTANEOUS INCISION.

The following case and remarks, by Dr. MACDONNELL, of Montreal, are abridged from the *Canada Medical Journal*, for November, 1852.

CASE. Mr. —, aged 30, two years ago, in an attempt to save an old man, who was maltreated by two strong young men, was knocked down by these men, and one of them bit out several pieces from about his face and hands, a portion of one ear, and the entire cartilage of the right ala of his nose, leaving but a small portion connected with the upper lip. He recovered soon from the effects of the beating, but the wound of the nose was a long time in healing, and left the nostril exposed on that side. He consulted a surgeon about a year ago, who undertook to remedy the defect by engrafting on the cicatrix a portion of skin removed from the back of the patient's hand. This was accordingly done, and the new substance retained *in situ* by adhesive plaster; as might be expected, no union took place. The patient now despaired of obtaining relief, and selected an occupation that required withdrawal from society. He came to Montreal to consult me. On his removing the adhesive plaster with which he had concealed the deformity, I was struck with the peculiar shape and size of the deficiency in the nostril, which could hardly have been produced in any other way than that already mentioned. I recommended him to take a private ward in St. Patrick's Hospital, and stated my opinion, that an operation would remedy the defect. On October 4th, assisted by Drs. David and Howard, and by Dr. Walter Jones, I performed the operation in the following manner:—A small narrow bladed knife was introduced between the skin and nasal bone, and carried upwards towards the edge of the orbit, care being taken to keep the blade close under the skin. When the point was felt in this situation, the edge was carried towards the mesial line so as to separate the integument from the bridge of the nose, which was rather prominent. The dissection being completed in this situation, the knife was carried downwards, still close under the skin, until it reached a level with the under edge of the nasal bone. The blade was then withdrawn, and entered under the remnant of cartilage before alluded to as being still connected with the cheek, and pushed toward the ear for about two inches, when the edge was turned upwards, and the dissection carried on until it joined that before made. By this plan, the skin was detached off the subjacent parts, from the median line of the nose all over the cheek, and the scalpel passed freely about in all directions. A large flap having thus been made, the edges of the cicatrix were pared and brought together, and the stump of cartilage joining the cheek, being brought into contact with the tip of the nose, was there maintained by a Dieffenbach's pin and twisted suture; two or three points of suture served to bring the remainder of the wound into apposition, and thus, what was before a semilunar cicatrix, appeared an incised wound, whose edges were in one line. To enable me to avail myself more fully of the flap detached from the cheek, an incision to the extent of little more than half an inch was carried from the outer edge of the nostril, by which the tension was taken off the new ala nasi, and a plug of lint being introduced into the nostril, the dressing was completed: the loose integument being pushed from the cheek towards the nose, and there retained by means of compresses and adhesive plaster. The operation was thus performed without making the least disfigurement of the face. Nothing remarkable ensued during the month the patient remained under treatment. He now has a complete nostril; the nose is straight and prominent, and except that, on the side operated upon, the lower edge of the ala nasi, at its junction to the cheek, descends about the twelfth of an inch more than the other, no difference is perceptible, as nothing marks the line of junction but a fine cicatrix.

REMARKS. The plan of operation in the foregoing case is a modification of the French method of autoplasty, or as it is sometimes termed, *la methode par glissement*. It differs from the French method, in the fact of the dissections being subcutaneous, which is a decided improvement, for it is often a question whether the plan adopted to remedy some of these

deformities does not leave a great amount of disfigurement. When a portion only of the nose is lost, then, as in the instance before us, the deformity admits of being remedied. The plan I adopted is preferable to that of taking a flap from the cheek, twisting it round, and adapting it to fill up the chasm; for besides the scar on the cheek, the want of any portion of cartilage prevents a nostril being successfully made. Whenever the surgeon can save a piece, no matter how small, of the original ala, he will find that it can be made to answer better for a margin than any piece taken from the cheek; for, besides rounding off the arch of the nostril and keeping the ala distended, it retains the property of dilatation and compression, owing to the insertion of the levator labii superioris *alæque nasi* being attached to it, as well as the lower fibres of the compressor nasi; and it is acted upon simultaneously with that of the opposite side, both in the acts of respiration, and the different emotional movements of the face. Although I have mentioned that the foregoing operation is a modification of the French method of autoplasty, yet it does not appear that French surgeons have ever availed themselves of the flap made by subcutaneous dissection; and it is evident, that the most recent writer on the subject is *unaware of the possibility of the defect being remedied in this manner*, for Jobert says, "On a réparé également par la méthode indienne le lobule du nez et même, dit-on, les ailes du nez. Pour moi, sans blâmer l'emploi de la méthode indienne pour réparer les difformités partielles du nez, je pense que lorsqu'il s'agit de son extrémité ou de ses ailes, il est préférable de tailler un lambeau aux dépens des joues ou des lèvres." *Traité de Chirurgie Plastique*. Tome premier, p. 256.

MIDWIFERY AND DISEASES OF WOMEN.

PROLAPSUS OF THE ANTERIOR WALL OF THE VAGINA AN OCCASIONAL CAUSE OF FETID, PHOSPHATIC, MUCOUS URINE.

We abridge the following communication by Dr. GOLDING BIRD, from the *Medical Times and Gazette* for Jan. 1st, 1853.

It is not very unfrequent for a physician to be consulted by females (generally about their grand climacteric), on account of their having great irritability of bladder, and the urine, when passed, being very fetid, and containing much ropy mucus. They generally complain of small quantities of the urine escaping on any sudden change of posture, or after violent coughing, and suffer no little distress from the offensive odour which, in spite of every precaution, clings to them. It occurred to me several years ago, that the cause of this state of urine was analogous—in some of the cases, at least—to that which exists in cases of enlarged prostate in the male: I mean a cause preventing the complete emptying of the bladder, and thus inducing the retention of a portion of urine sufficiently long to allow it to undergo decomposition.

Almost the first case in which I recognized this condition, occurred about eight years ago, in the person of a stout, tolerably healthy-looking woman, who had been the mother of several children, and had ceased to menstruate for three or four years. She complained of great sense of distress in the lower part of the abdomen, with weight and bearing down. Walking was painful to her, and she was almost constantly tortured with a desire to empty the bladder. The urine was very offensive, and contained a large quantity of dense ropy mucus, mixed with phosphates. Suspecting the possible presence of a calculus, I introduced a catheter, but little urine escaped, and no concretion could be felt. But, on examining the vagina, a large pink looking sac depended from its anterior wall, and almost separated the labia. She was suffering from prolapsus of the bladder into a pouch formed in the anterior vaginal wall. By keeping the bladder emptied by the daily use of the catheter, the urine soon recovered its healthy appearance, and the mucus decreased considerably. The decomposition of the secretion in this vesical pouch had evolved ammonia, which had irritated the bladder and caused a copious secretion of mucus, loaded with the earthy salts. I sent the patient to my brother, Dr. Frederic Bird, as I believed no permanent cure could be obtained while the prolapsus existed. He applied the actual cautery to the anterior wall of the vagina, and the result was most satisfactory. After the slough came away, sufficient contraction occurred to prevent the formation of the vesical pouch, and the patient remained free from the ailment.

I have met with so many analogous cases, that I am persuaded that a very large proportion of cases of fetid phosphatic mucous urine in the female, may be traced to the imperfect emptying of the bladder from prolapsus of the anterior wall.

wall. Every one is well aware of the frequency of enlarged prostate as a cause of this state of the urine in the male, and the circumstances to which I have now drawn attention will be found to be as frequent a cause of this state in the female. In more than one instance, I have seen complete prolapsus of the uterus produce a similar result, evidently by drawing the bladder out of its position, and thus interfering with its being perfectly emptied.

So far as I have seen, the ailment in question is nearly, although not exclusively, confined to females who are called upon for laborious exertion too soon after their confinements. I have met with but very few cases in the higher ranks.

I have seen many poor women deprived of the means of earning their bread as domestic servants, from the apparent incurability of the ailment. A few months ago, a lady who resides in my neighbourhood, informed me that she was under the necessity of discharging her cook, on account of the urinous and even fetid odour which exhaled from her person. The poor woman had been out of place for a long time before entering this lady's service, on account of this very ailment. I found the urine to be strongly alkaline, exceedingly fetid, and loaded with mucus and phosphates. She never had been married, but had suffered, as she fancied, from prolapsus of the uterus for many years. I found that, after emptying the bladder by the catheter, the urine secreted and removed in half an hour was slightly acid, and scarcely fetid. The following morning, before she passed water, I discovered the labia to be separated by a large soft red body, which proved to be the depending anterior wall of the vagina, filled with her prolapsed bladder. The use of an injection of infusion of galls three times a-day into the vagina, the wearing of an abdominal support with a perineal pad, and the administration of iron and quina, with dilute phosphoric acid, soon restored her to health and comfort, and enabled her mistress to retain her services.

A nearly identical case occurred in the person of a servant of a lady of rank, who had obtained for her the opinion of several of our most distinguished surgeons, as she was supposed to be labouring under calculus. She was completely relieved in a similar manner. But there was a curious fact connected with this case, which I learned from the mistress. After failing to obtain relief from legitimate sources, she had been induced to consult a "wise woman", residing in the village where her lady's country residence was situated. This sibyl told her that she laboured under "sinking of the womb", and that she could cure her. On her next visit, the woman introduced something into the vagina. The operation gave her very considerable pain, but, to her great delight, it certainly diminished the irritability of the bladder and offensive character of the urine. She retained this body for some months, when it fell out; and, on its being shown me, I was rather surprised to find that it was a large smooth black siliceous pebble, common in the beds of brooks and shallow streams. Whatever induced the old woman to make her diagnosis, her clumsy substitute for a pessary had afforded no small relief.

I would, in conclusion, advise that, whenever a female is found to labour under the annoyance and distress, accompanying the excretion of fetid mucous phosphatic urine, the state of the uterus and vagina should be carefully examined when the bladder is distended; and I believe the ailment will be often cured by relieving the prolapsed state of that viscus.

COMMUNICATION OF OVARIAN CYSTS WITH THE FALLOPIAN TUBES.

M. ADOLPHE RICHARD, in the *Mémoires de la Société de Chirurgie de Paris*, tome iii, fascicule 2, directs attention to certain cases of ovarian disease, in which the cyst opens into the Fallopian tube. He has observed five cases of this description.

CASE I. The body of a woman, aged from twenty-five to thirty years, was brought into the dissecting-room. She had died of typhoid fever. When the abdomen was opened, there appeared a large ovarian cyst, with apparently a portion of the small intestines adhering to its front: on removing the parts, however, this was found to be a portion of the Fallopian tube. The entire broad ligament of the left side was distended by a cyst of the size of a child's head, of pretty regularly spherical form, on the anterior face of which was the Fallopian tube, which was easily recognised by its connexion with the uterus. The tube was of normal size at its inner third; it then began to enlarge, and, in the whole of its outer half, was of the size of the small intestines. It formed several flexuosities like those of the intestines, and was lost in the walls of the cyst, at the centre of its external surface. All the enlarged portion of the tube was full of fluid; and on even slightly pressing on the cyst, it was evident that they

communicated. On the inner surface of the tube, the folds of mucous membrane were half obliterated. About three-fourths of an inch before its termination in the cyst, the abdominal orifice of the tube was represented by a sort of transverse valve. From this point to the cyst, the tube was much dilated, and presented longitudinal folds, evidently formed by the fimbriae, connected by membranous deposit.

Cysts in the broad ligament may originate from the peritoneum, the uterus, all parts of the Fallopian tube, the ovarian ligament, and especially from the *débris* of the Wolffian body. Ovarian cysts are recognisable by the presence of the atrophied ovary on the inner wall, as the presence or absence of the testicle on the walls of the cyst indicates the origin of hydrocele.

CASE II. In another woman, much older than the preceding, the ovarian cyst was smaller, but had thicker walls, and was bound round by the tube, much more dilated than in the last case, and opening on the posterior aspect of the cyst. The remains of the ovary were found spread out in the walls of the cyst.

CASE III. In a woman who died of puerperal peritonitis, the ovary and Fallopian tube on the right side were healthy: the former contained a *corpus luteum*. On the left side, there was a multilocular ovarian cyst, not very large: the ovary forming its inner wall, projected instead of being spread out. On the outer side, the communication with the tube was formed by a short, narrow passage, succeeded by a more sudden and spherical enlargement than in the preceding cases.

CASE IV. In a young woman who had died of phthisis, the only appearance which at first presented itself was enlargement of the external part of the Fallopian tube. The ovary appeared to be merely increased in size; but, on pressure, fluctuation was felt in it; and on opening the parts, there was found to be a narrow circular opening into the tube from the ovarian cyst, which was formed in the centre of the gland. This may be considered as representing the first stage of the disease.

How was the fluid retained in the Fallopian tube? M. Richard ascertained by means of a catheter, that nothing separated the dilated from the normal portion; and he attributes the non-passage of the fluid to the narrowness of the uterine portion, and the tonicity of the parts. Sometimes, however, the fluid does escape. In the atlas of Boivin and Dugès, there are two figures, described under the name of dropsy of the tube, which resemble the cases described above. (*Traité Pratique sur les Maladies de l'Uterus, avec Atlas: planche xxxv.*) In one of these, the tube was dilated as far as the uterus. M. Follin presented to the *Société de Biologie* a dilated uterine tube, from which fluid escaped by the uterus. Morgagni, in his second letter, *De Sedibus et Causis Morborum*, refers to a case, related by Sponius, in which a cyst in the abdomen was connected with the Fallopian tube, and communicated with the uterus; so that there was a constant serous flow from the genital organs of the patient. Frank (*De Curandis Hominum Morbis*, lib. vi, pars prima) speaks of a woman in whom a pint of fluid escaped daily from the uterus and vagina. She died of phthisis; and a hundred and thirty pints of glairy fluid were found in the left Fallopian tube.

Of the cases in which ovarian dropsy has been said to be evacuated by an opening through the peritoneal *cul-de-sac* of the vagina, M. Richard believes that some must be referred to escape of the fluid through the Fallopian tube.

M. Richard ascribes the origin of these tubo-ovarian cysts to distension of a Graafian follicle after the discharge of the ovum, instead of forming a *corpus luteum*.

TOXICOLOGY.

DR. COGSWELL'S EXPERIMENTS ON THE LOCAL ACTION OF POISONS.

THE following is an abstract of a paper by Dr. COGSWELL on the Local Action of Poisons, published in the *Lancet* for November 27, 1852.

The object of the author is to show that the number of those agents can be greatly extended, which are capable of producing local impressions on the part to which they are applied. Hitherto, the dynamic agents ascertained to act locally have been five,—monkshood, hydrocyanic acid, opium, tincanas, and the poison of the viper. The evidence always consists in the privation of power, whether of sensation or motion. Dr. Cogswell confines his attention to the question, whether the substance experimented with does or does not affect the phenomenon of motion.

He criticises the conclusions arrived at by Dr. Wilson Philip and Messrs. Morgan and Addison; the former of whom asserted

that the injection of an infusion of opium into the intestine of a rabbit produced almost instant paralysis of the gut; while the latter state that ticusas, applied to the outer coat of the intestine of a guinea-pig, caused instantaneous and complete suspension of the peristaltic movement. In repeating the experiment with opium, he found that "the immediate effect was an energetic contraction of the bowel towards the axis, attended certainly with a suspension of the peristaltic movement; but this, clearly because the effect of the foreign body had been to *stimulate*, so as to throw the circular fibres of the muscular coat into irregular and excessive action, sometimes even temporarily reducing the part to the condition of a mere cord." The same effect is produced by gentle irritation with the point of a knife, by opium in strong infusion, hydrocyanic acid, conia, and nicotine. It is, however, very possible, Dr. Cogswell thinks, that opium and ticusas may have a tendency to paralyse the bowel after an appreciable lapse of time. "Such, at least, appears to be the case with conia and nicotine, which are peculiarly adapted for trying the experiment. Minute portions of these fluid alkaloids being applied to the intestines of newly-killed frogs, the first phenomenon was always a local constriction; but in an hour, more or less, the parts to which they had been respectively applied presented a remarkable bulging outwards, as if they had become flaccid from paralysis. Conia and nicotine, applied in like manner to the voluntary muscles of the frog, produced vivid contractions of the fibres at the points of contact. Hydrocyanic acid, opium (in strong infusion), alcohol, chloroform, and the dilute mineral acids, all had the same effect—that of causing the muscles to contract. With regard to the subsequent effect on the voluntary muscles, I was unable to judge by this method. If there really be any substances which *immediately* paralyse by a local impression on the extremities of the nerves, it would appear that we have as yet no sufficient reason for including opium and ticusas among the number."

The substances used by Dr. Cogswell were the sulphuric, nitric, and muriatic acids, alcohol, ether, chloroform, hydrocyanic acid, opium, muriate of morphia, codeia, narcotine, extract of hyoseyamus, atropia and its sulphate, nicotine, aconita and its sulphate, conia, and theine or caffeine. They were injected in solution beneath the skin of the leg in frogs. Excluding narcotine, which produced no effect, and the mineral acids, as chemical irritants, all the substances produced local paralysis. The following is the account of one of the experiments: we quote it as a general type of the results arrived at by Dr. Cogswell:—

"**MURIATE OF ACONITA.** An eighth of a grain of this alkaloid, nearly dissolved in water by the addition of muriatic acid, was tried. In less than a minute, the animal's control over the leg was impaired; and presently it dragged the whole extremity in moving from place to place, but still, as in the previous instances, it could use the limb by a strong effort of the will. In five minutes it lay relaxed and insensible; in twenty minutes it had a convulsive quivering over the whole system, not, however, including the limb that was operated on; in half an hour it appeared to be dead. The muscles of the right hinder extremity contracted under the galvanic stimulus, but not those of the left. The results were very similar on repeating the experiment, including the convulsive movements."

DR. ALBERS ON THE PHYSIOLOGICAL ACTION OF THEINE AND CAFFEINE.

In the *Deutsche Klinik* for December 18th, 1852, Professor ALBERS, of Bonn, has recorded the results of some experiments with citrate of theine and caffeine, which are interesting in connexion with those of Dr. COGSWELL.

He introduced a grain of citrate of theine under the skin of a frog's leg. In twenty-five minutes, this limb became stiff; the other leg remained moveable, but in a few minutes became stiff like the first. In a very short time, the rigidity extended to the anterior limbs, which, like the others, remained extended, so that the frog could not turn over when laid on the back. The pectoral muscles and the whole body now became rigid; and this state continued during two hours. On opening the body during this time, Dr. Albers found the heart pale, and rigidly contracted to one-half of its normal circumference; and it was only possible, by means of a powerful stream of electricity, to excite some single contractions in a small part of the heart.

A second frog was treated in the same manner with citrate of caffeine. Here the limb operated on became, after fifteen hours (minutes?), stiff; and this was in a few minutes followed by rigidity in the other limbs, and afterwards in the whole body. In three quarters of an hour, on opening the body, the heart was found pale, and contracted to half its proper size.

In both cases, electricity produced muscular contractions in the limbs and body; but they were much more feeble and less frequent in the limbs which had been operated on. In this point, Dr. Albers' experiments closely agree with those of Dr. Cogswell.

In producing spasm of the heart, Dr. Albers says that theine and caffeine differ remarkably from the most energetic narcotics, as nicotine and conia; after the administration of which, in the manner described, and when the limbs and body were paralysed or convulsed, the heart continued to beat in its normal manner. By reference to the action of caffeine and theine on the heart, which is more marked than that of any other known article, Dr. Albers would explain the ready production of palpitation, pain, and distressing feelings, in those who have drunk strong tea.

Dr. Albers finds that the action of caffeine on warm-blooded animals, as rabbits, is less violent than on frogs; in the latter, it acts more powerfully than strychnine. He refers to some experiments by Dr. Cogswell, showing that the same effect is produced when caffeine is introduced into the mouth of a frog, as when it is placed beneath the skin of the thigh.

In practice, citrate of caffeine is given in doses of from three to five grains, in neuralgic headache and other nervous affections. After one or two doses, it brings relief. Dr. Albers finds that it succeeds best in females. The above-mentioned researches show that its use should not be carried too far.

POISONOUS PROPERTIES OF THE CALABAR BEAN

Attention has been directed recently to the Calabar bean (or nut, as it is called), which is used as a poison in its native country. It is the seed of a species of *Erythrophloeum*, belonging to the natural order Leguminosae, and the suborder Mimoseae. Dr. Christison recently made an experiment by swallowing about a quarter of a seed, and it produced in him alarming symptoms, similar to those produced by poisoning with aconite.

EDITOR'S LETTER BOX.

THE VERDICT OF MANSLAUGHTER AGAINST MR. HICKS.

LETTER FROM PATRICK BENSON, ESQ., TO THE EDITOR.

SIR,—My attention has been drawn to an article in your Journal of the 4th instant, headed "a verdict of manslaughter against Mr. Hicks by a coroner's jury", in which you have been pleased to make sundry severe remarks on my conduct in the case.

I must beg to say that I think that, in common fairness, you might have suspended any remarks until the case was ended, and you had both sides fully before you. The statement forwarded to you is evidently *ex parte*; but as the matter has yet to come before another tribunal, I shall at present refrain from entering into any controversy on the subject.

This much I will say, (as I do not conceive that these points can affect the position of Mr. Hicks, as a defendant), with regard to Mr. Hicks not having notice of the *post mortem* examination, that I was requested by the relatives of the deceased to make an examination of the part affected, merely to see whether the bone was broken or not. This I did, in conjunction with Mr. Tomson; and then recommended the child to be buried, without expressing any opinion as to the cause of death. We had not the *least idea* of any ulterior proceedings whatever; nor was it until a month afterwards that an inquest was determined on, of which I was wholly ignorant, and had not the slightest intimation of it until the Saturday evening previous to the Monday on which the inquest was held.

I admit, and much regret, that Mr. Hicks had no legal adviser at the inquest. But it was not my fault that he had not one; for before giving my evidence, (having observed the impression apparently made on the jury by the evidence of the mother), I earnestly pressed on Mr. Hicks, jun., the absolute necessity of procuring legal assistance, and begged of him to apply for an adjournment for that purpose. He, however, refused; and, although he and his father were present, they never cross-examined a witness, nor made any observation whatever; had they done so, they might have elicited answers favourable to his case.

In reference to insinuations contained in your article, attributing base and dishonourable motives to Mr. Tomson and

myself for the evidence we had given,—namely, that Mr. Hicks had been called in to our patients; for myself, I repel such insinuations, as wholly untrue. I have no recollection of Mr. Hicks ever being called in to a patient of mine. Mr. Hicks and I have been on most friendly terms since the commencement of our acquaintance. I have always entertained, and still entertain the most friendly feelings towards him: and no person can regret more than I do the result of the inquest.

Trusting in your impartiality to insert this letter in your next number,

I am, etc.,

PATRICK BENSON.

Luton, Bedfordshire, February 12th, 1853.

THE INCOME TAX.

LETTER FROM DR. THOMAS SMITH, CHAIRMAN OF THE INCOME TAX COMMITTEE OF THE ASSOCIATION, TO THE EDITOR.

SIR,—The Income Tax Committee rejoice to perceive that members of the ASSOCIATION are at last thinking of bestirring themselves to obtain a repeal, or more equitable adjustment, of the Income Tax; and that the pages of our Journal are no longer silent regarding the hurtful nature of that odious and unfairly levied impost. Till lately, the Committee have had their exertions frustrated, and their energies damped, by the want of any support from our Journal, from members of the ASSOCIATION, or from the general body of the profession. About twelve months ago, the Committee made an earnest appeal to their brethren to do that which has recently been mooted: viz., to assemble special meetings of the different Branches of the ASSOCIATION, so as to have the best method of proceeding fully discussed, and energetically acted upon. What was not then listened to, may, perhaps, now meet with a response. If deemed expedient, the Branches might nominate gentlemen to form a deputation to wait upon the Chancellor of the Exchequer, and various other members of Parliament, for the purpose of explaining to them the special grievances to which all grades of the medical profession are now subjected by reason of this tax. Petitions to Parliament might also be agreed upon, and signatures obtained from the profession generally. This would not be difficult, as the subject is one on which scarcely a shade of diversity of opinion exists.

There is one feature of the injustice to which we are subjected, to which I am anxious to call attention, because I think that it has not in any quarter received that amount of consideration and condemnation which it merits. I allude to the monstrous injustice of assessing professional men upon the *last year* of their receipts, which, with young men struggling upwards, is generally their best; whilst merchants and tradesmen are taxed upon the average of the *last three years*. In this way the professional man is obviously placed upon the severest extremity of the rack of extortion; and in many places he is compelled to return an exaggerated report of his yearly receipts, to prevent him from sustaining injury through the injurious gossip of Income Tax Commissioners and their underlings.

But my object in addressing you is not to write against the Income Tax, but to beseech the profession to make known their complaints. Members of Parliament assert that the profession, as a body, are indifferent on the subject; and assuredly the statement derives apparent confirmation from the small number of petitions which have as yet been forwarded to Parliament by medical men. I will only add, that the Income Tax Committee of the ASSOCIATION are anxious to do their duty; but that they feel that all their efforts must prove useless unless they are supported, by the Branches holding simultaneous meetings, petitioning against the tax, and endeavouring to enlist, in support of the prayer of the petitions, a large number of members of the House of Commons. Let the period between this and Easter be employed in getting up influential meetings and numerous signed petitions; and during the recess, when members of Parliament return to the country, let them be waited upon, and urged to help our just cause. I am, etc.,

THOMAS SMITH, M.D.,

Chairman of the Income Tax Committee of the Provincial Medical and Surgical Association.

Cheltenham, February 14th, 1853.

[A requisition to the Council of the Metropolitan Counties Branch, to call a Special General Meeting of the members, to consider the propriety of petitioning against the Income Tax injustice, is now in course of signature; and in other parts of the country a similar movement is on foot. As the time for action is brief, we trust that none of it may be lost.—EDITOR.]

PETITION AGAINST THE INCOME TAX BY THE MEDICAL PRACTITIONERS OF ST. ALBANS.

LETTER FROM J. T. LIPSCOMB, Esq., TO THE EDITOR.

SIR,—You may, perhaps, be glad to hear that the letter of your correspondent, Dr. Nankivell, published in the Journal of January 28th, has had the effect of arousing the medical practitioners of this place to a due sense of the injustice done to the medical profession and others depending alike on precarious incomes, by the present unequal imposition of the Income Tax. They have forwarded a petition on the subject to one of their county members, for presentation to the House of Commons, and also a copy to the Right Honourable the Chancellor of the Exchequer, respectfully requesting his attention to its prayer.

I am, etc., JOHN THOMAS LIPSCOMB.

St. Albans, February 8th, 1853.

DISULPHATE OF QUINA, "HOSPITAL SULPHATE OF QUININE", AND SULPHATE OF QUINIDINA.

LETTER FROM DENHAM SMITH, Esq., TO THE EDITOR.

SIR,—You send me samples of "hospital sulphate of quinine" (Herring's), and of "sulphate of quinidin (Howard's and Kent's)"; the latter "a salt about half the price of quinine"; and ask me to examine them, and tell you what I think about them, in comparison with the disulphate of quina.

Both samples sent differ in aspect from disulphate of quina, being denser, and in larger crystals, than this salt. The "hospital sulphate" is coloured. Solutions in warm water of the three salts were submitted to the following tests:—

Lime water.	Each gave precipitates, soluble in excess of precipitant.
Chlorine-water and ammonia.	Each gave a dark green precipitate.
Chlorine-water and potash.	Each gave a yellow precipitate.
Chlorine-water and saturated solution of ferrocyanide of potassium.	Each gave a full crimson-red precipitate, rendered fuller and denser on the addition of a drop of solution of ammonia.

Each salt dissolved in sulphuric acid without blackening.

The only tests of any practical value, to distinguish disulphate of quina from sulphate of quinidina, which I at present recollect, are the asserted difference of solubility, and the chlorine-ammonia reaction. I have a note, but not the authority, that sulphate of quinidina is soluble in four parts of boiling water: the sample you sent me, thus marked, required upwards of twenty parts to effect its solution. M. Leers, in a paper lately published in the *Annales de Chimie*—elaborate enough, if this be any guarantee of correctness—relies on the chlorine-ammonia test to distinguish quinidina from quina and cinchonia; but with the specimens you sent, this test gave evidence in favour of their identity with the pure quina salt.

The conclusion to be drawn from these experiments is, either that disulphate of quina, the so-called "hospital sulphate of quinine", and the specimen of "sulphate of quinidina", are identical as respects their bases; or that the two latter contain so large an amount of the quina salt as to completely shroud the distinctive character, if such there be, of quinidina.

I offer no opinion as to whether quina and quinidina are identical or distinct substances; or whether they are the same body existing under somewhat different conditions and aspects, like sublimed and precipitated sulphur; nor do I assert that the three salts I have examined are absolutely identical, since a further and more elaborate investigation, which might be appropriately instituted by a qualified officer of the Pharmaceutical Society, would possibly point out some distinctive character: all I say is, that the recognised and best known tests have failed to do so. The practical result to be drawn from this investigation seems to me to be, that, as the "hospital sulphate of quinine" and the "sulphate of quinidina" are sold at about half the price of the disulphate of quina, and the chemical resemblances of the salts are so striking, it is worth while, merely as an economical question, to institute a series of experiments to determine the respective values of these salts as therapeutic agents. I am, etc.,

J. DENHAM SMITH.

Putney, February 16th, 1853.

P.S. Let me restore the capital and characteristic test for quina of chlorine-water and ammonia to its real owner, Mr. Meeson, who, whilst a student at one of the Borough schools, some years since, discovered this reaction, which has been appropriated by a German chemist, named Brandes. Instances of this kind are far too frequent to be always accidental, and deserve exposure when opportunity offers.

NEWS AND TOPICS OF THE DAY.

ESTIMONIAL TO ROBERT E. GRANT, M.D., PROFESSOR OF COMPARATIVE ANATOMY IN UNIVERSITY COLLEGE.

SOME time ago, the friends of Professor Grant, deeply impressed by his great merits as a devoted and successful votary of science, resolved to present him with such a testimonial of their admiration as would, in some degree compensate for the inadequate income which he derives from his professional and other appointments. The result of the subscription has not turned out quite so large as might have been expected, but it has enabled the committee to purchase a microscope of the value of fifty guineas, and a deferred annuity of fifty pounds, which was recently presented to Dr. Grant, at a meeting of the contributors held in the Museum of Materia Medica, University College, and presided over by Dr. Marshall Hall. The deferred annuity of fifty pounds commences at the termination of his tenure of the Swiney Professorship of Geology, which can only be held for five years. We understand, that before the committee resigns its functions, an urgent memorial will be presented to Government for some portion of the £1,200 annually given to eminent scientific discoverers and authors.

The following is the principal part of the speech in which Professor Grant acknowledged the presentation of the testimonial:—

"Gentlemen, there is no form of compliment which you could have proposed to me more congenial to my taste, or which could have been more highly appreciated, or which would be more likely to prove of valuable service to me, than the complete and splendid microscope you have now placed before me. And let me add, that the highly complimentary and gratifying inscription you have caused to be engraved upon it, very greatly enhances the value of this rich gift in my estimation.* For the last forty years of my solitary pursuits in natural history, on the continent and at home, no source of scientific improvement, or of intellectual gratification, or of refined and enduring pleasure, has equalled that derived from the marvellous instrument which has revealed to me so many novelties, and beauties, and wonders, in the part of nature's works to which I have ever been most fondly attached. The numerous and complicated improvements which the advances of science and the arts have of late years added to the microscope, have greatly increased its value as a means of philosophical research, but they necessarily tend to place it beyond the reach of mere naturalists, and to render it less easy to keep pace with the march of improvement in that direction. In earlier years, it has more than once been proposed by my pupils in this College, to confer upon me some mark of their esteem, which I have systematically opposed, upon the obvious ground, that its burden would necessarily fall upon the very few pupils who then attended my classes, and to whom I was already specially obliged. But, on the present occasion, the kind intention of my friends and former pupils, did not appear to me liable to the same objection. As a token of regard from gentlemen so competent to judge, and who so long have had the means of knowing and estimating my career as a teacher and as a man, and with several of whom I have been intimately connected by the ties of friendship, and by many pleasing associations of early life, the worth of your donation will be more highly appreciated; and this instrument will ever claim to be prized by me beyond its high pecuniary value. In regard to the sacrifices to science alluded to by the learned chairman, and to the remunerative character of zootomical and zoological pursuits, I may now, at this late period of my career, presume to form an opinion, as next year I shall have been forty years an author on comparative anatomy, and also exactly thirty years a public teacher of that science; and I must say, for those who may follow, that my whole past experience convinces me, that no avocation to which the human mind could be directed, approaches, in its remunerative character, in the sense of affording the most pure, elevated, and durable happiness, to that to which my past life has been devoted. And had I now life to recommence, and my selection of a pursuit again to make, I could have no hesitation in choosing that which has crowded into my existence the greatest quantity of the highest enjoyment which can fall to the lot of frail humanity. The very kind respect ever

shown me by my fellow-labourers in this rich vineyard of science, at home and over Europe; my habitual contemplation of the most marvellous and beautiful scenes presented by the material or intellectual universe; the proud feeling of acquired superiority in the comprehension and the interpretation of a portion, however small, of the book of nature; the perfect union through life of my private tastes with my agreeable and healthful public duties; the consciousness of having been useful, within my circumscribed sphere, to the progress and the diffusion of a neglected science among my fellow-men; and the great and unceasing pleasure of communicating daily to the uninitiated the knowledge which has been accompanied with so much pleasure in acquiring."

TESTIMONIAL TO DR. SINCLAIR, J.P., WICK, CAITHNESS. On the evening of the last day of 1852, a numerous meeting of the friends of Dr. Sinclair, acting as a committee of management for a testimonial to him, met in the Wellington Hotel, Wick, the Rev. Mr. Whyte, of Canisbay, in the chair.

The Chairman addressed the doctor, expressing his own grateful sense of the honour of presiding at so large and highly respectable meeting, and of expressing, to the best of his humble abilities, sentiments of esteem and admiration for the doctor's rare and varied accomplishments. His refined taste and scientific pursuits had gained him the respect and esteem, not only of his neighbours and acquaintances, but of strangers from all parts of the kingdom and from foreign lands, who had spent many pleasant hours in visiting the large and splendid museum of natural history and antiquities, prepared and collected by his own hand. His high talents and abilities in his profession, combined with prompt and seemingly intuitive decision for every occasion, together with his self-denying readiness at every call from rich or poor, had endeared him in the hearts, and established him in the confidence, of those who have the benefit of his assistance; so that, while his visits, whether professional or social, were cordially welcomed in the mansions of the great, his ready skill and sympathetic tenderness caused his visits to be regarded as those of a pitying and ministering angel in the cottage and the hovel. It was chiefly from the middle and labouring classes that subscriptions had been derived, and the collectors reported that each individual subscription was given with the cordial good-will, and with the earnest wish that thrice the amount could have been bestowed. In presenting the doctor with the purse and its contents, he begged, in the name of the 2,500 subscribers, that he would esteem it less for its intrinsic value, than as a token and pledge of their confidence and esteem.

Dr. Sinclair replied in a suitable address.

DR. MARSHALL HALL and DR. REYNOLDS. It is stated in the *Medical Times* of the 5th current, that Dr. Marshall Hall has introduced Dr. Reynolds to his patients in the following valedictory circular:—

"I now leave you in the care of Dr. Reynolds, in whom you may, as I do, place an unbounded confidence.

"Dr. Reynolds has gone through all my experiments with me, and has been constantly present lately at all my consultations, and knows my views perfectly.

"Dr. Reynolds' grandfather was physician to George the Third. What is more to the purpose, Dr. Reynolds distinguished himself both at University College and the University of London, taking five gold medals and two scholarships, and early took a special interest in the nervous system and its diseases. I published an observation of his so long ago as 1848.

"My intention for the present is to travel. I shall probably return to London yearly, during the months of May, June, and July, joining my friend Dr. Reynolds during those periods.

"During my absence, Dr. Reynolds will correspond with me relative to my patients.

"I fully expect that Dr. Reynolds will pursue with energy, and with advantage to the public, the career of investigation of the diseases of the nervous system which I have begun.

"I am, my dear Sir, yours very truly,

"MARSHALL HALL.

"38, Grosvenor Street, January, 1853."

MIDDLESEX HOSPITAL. At the last meeting of the governors, Sir R. H. Inglis, Bart., in the chair, the Marquis of Salisbury and the Rev. Dean Morell were elected Vice-Presidents, to succeed the late Duke of Wellington and Lord Cottenham. It was then resolved to appoint a second physician. It appeared from the report, that the expenditure exceeded the income last year by £2,100.

* Presented to ROBERT EDMOND GRANT, M.D., F.R.S. L. and E., F.L.S., F.G.S., etc., Professor of Comparative Anatomy and Zoology in University College, London, by his friends and former pupils, as a testimony of their esteem for his private worth, and of their sense of his eminent services in the cause of science, 1853.

WESTMINSTER HOSPITAL. The posts of Surgeon and Assistant-Surgeon to this institution are vacant—the former by the resignation of Mr. B. Phillips. Mr. C. Gardiner Guthrie is a candidate for the appointment of Surgeon, and Mr. W. A. Hillman for that of Assistant-Surgeon.

BETHLEHEM HOSPITAL. Sir Alexander Morison and Mr. Nicholls have resigned their respective offices of Physician and Steward of this establishment.

SMALL-POX HOSPITAL. At the annual meeting of governors, held in the board-room, Highgate, Joshua J. Redford, Esq., in the chair, Mr. Clift read Mr. Marsden's report. Since the removal of the hospital to its present site, a marked improvement in the patients had taken place: erysipelas or gangrene, which prevailed in the former hospital, seldom appeared. During the year, there were admitted 800, being an increase of 88 over any other year since the foundation of the hospital in 1746. Singular to say, the same number (230) of unvaccinated cases were admitted last and the preceding year. During the year, 690 recovered, and 110 died; while 666 were vaccinated, and 555 medical practitioners were supplied with vaccine lymph. The subscriptions amounted to £2352: 6: 11, and the disbursements to £1860: 19: 3. The late Robert Nicholson, Esq., bequeathed £1356, and the executors of Admiral Sir Charles Ogle, Bart., presented £470 to the institution.

DEATH FROM PRUSSIC ACID: INQUEST AT NOTTINGHAM. An inquest was held on Thursday the 10th instant, on view of the body of the Rev. James Flamank, an insane gentleman, residing with Charles Merit Rigg, a person who styles himself physician and surgeon, but who, it appears from the newspapers, has lately settled at Northampton as a homœopathic practitioner. We find his old address still given in the Directory, viz., 20, Devonshire Road, Wandsworth Road, Surrey. It appears that when Mr. Rigg dispensed his medicines in the Wandsworth Road, he had, *inter alia*, bottles of prussic acid; but whether one of them travelled with him to Northampton or not, he was not prepared to declare. However that may be, the unfortunate deceased obtained a bottle of this poison, by taking which he committed suicide. He survived an hour and a half after he was found labouring under the effects of the poison. He was found lying on the floor of a water-closet, vomiting. When seen by a practitioner, who was called in three quarters of an hour after he was found, he was in a state of collapse: his breathing was stertorous; the pupils were insensible to light, but not dilated. His skin was cold and clammy, and the pulse exceedingly feeble and intermittent. In a very few minutes it was not perceptible at the right wrist. The pulse at the carotid artery was 80, and not full.

On *post mortem* examination, the brain was found generally softened, especially the cerebellum. The veins were much congested. The heart was large and fat, but free from valvular disease. The liver, kidneys, spleen, and small intestines were healthy. Prussic acid was detected in the stomach and its contents.

The jury returned a verdict "that the deceased died from the effects of prussic acid: but there is no evidence as to whether he took it accidentally or otherwise." (Abridged from *Northampton Herald*, February 12, 1853.)

DRAINAGE OF EDINBURGH. At a meeting of the Architectural Institute of Scotland, on Thursday night, a communication on the drainage of the city of Edinburgh, by Alfred Lancefield, Esq., C.E., was read. He stated that the drains were wholly unventilated, with almost the single exception of that from the Royal Exchange, which was unique in its construction. Many of the drains ran into each other at right angles, a mode of construction which frequently resulted in their getting choked up. He recommended the egg-shaped drains as the most useful; and in alluding to the noxious gases which were often accumulated from the imperfect ventilation of those at present in use, stated that on one occasion, when a labourer employed by him was entering a drain with a lantern in his hand, an explosion took place by which the man was severely hurt. From the imperfect trapping of many of the drains, he had no doubt that this obnoxious effluvia found its way into the houses of the inhabitants in various quarters of the city. He complained of the general narrowness of the main drains in the city, and contrasted them with those of London and Liverpool, where they were of enormous size. All main drains should be of such a size as to admit of a person going into them; and they should always have side entrances. He hoped that the drains would soon be constructed on more scientific principles, —and that the streams around the town would not always be used for common sewers.

GLASGOW SOCIAL STATISTICS. The annual report of Dr. Strang, city chamberlain, on the mortality bills of the city of Glasgow for 1852, states the real average figure of mortality in that city in proportion to the living, to be as 1 to 34·8. The cost of maintaining the poor in the four parishes of Glasgow, which, in 1848-49, was 105,260*l.*, was only 78,733*l.* in 1850-51—the return for last year not being complete. The bankruptcies connected with Glasgow have decreased by 20, compared with the year 1851. The writer urges the authorities to adopt stringent sanitary measures for the improvement of the city. "Try (he says) by every means in your power to open up densely peopled quarters to more light and air than they now possess, and to preserve open spaces in the suburbs capable of ere long becoming the lungs of a future city. Endeavour also to control, as much as is consistent with the rights of property, the construction of dwelling-houses, school-rooms, and workshops, with a view of affording better ventilation, purer air, and greater comfort to their occupants; to extend the already great improvements made in our sewerage and drainage; and to control still further the cess-pools and other noxious agencies which affect the public health and public comfort; endeavour, in fine, to procure for this growing community that indispensable element of internal and external cleanliness—a constant and an abundant supply of pure water, coupled with every one of the other sanitary improvements which the wise and the philanthropic have of late years advocated."

MEDICAL EXAMINATION OF APPRENTICES TO TRADES. In a letter in the *Northampton Herald* for 12th February, Mr. Henry L. Smith, of Southam, makes the following remarks.

"I must now draw attention to the following social evils, and suggest a remedy. I have found, in nearly fifty years' experience, that there is a great sacrifice of human life by boys being thoughtlessly apprenticed to employments and trades, and even professions, for which they are not physically, morally, or intellectually qualified. I think it would be a great boon to those who desire to provide for their own household, which so many of your industrious artisans of Coventry manifestly do, if the committee of the Provident Dispensary were to issue a notice requesting parents to send their sons to a committee, to be called the "Apprentice Committee," and which might be selected from your honorary subscribers and the medical staff, to meet, say once a fortnight, for the purpose of examining all boys whose parents might desire it, before binding them apprentice to any employment or trade, and to report whether they were fitted for the same. I believe that hitherto there have been yearly more persons destroyed wholly in their lives, or partially in their faculties, by the chance method of entering on employments and trades for which they are not fitted, than people are aware of; and that the military and naval services of the country have not destroyed so many people as has been the case in this particular, for the want of some social arrangement among ourselves.

"If in practice this preliminary examination was found useful, it might easily be made imperative; and on the back of a boy's indenture might be written a certificate something like the following:—

"This is to certify that we, the undersigned, members of the Apprentice Committee, have, this day, with the assistance of A, B, C, surgeons of the Provident Dispensary, and also C, D, men in the same employment the boy is to be apprenticed to, examined E F carefully, and find him able to bear the labour of so-and-so (say a shoemaker), or the necessary confinement in one posture (say of a tailor); or the necessary confinement in a close and crowded atmosphere (say of a weaver); or the vegetable, animal, or poisonous exhalations of so-and-so, or any other special objections that are known to belong to special trades, by those who have suffered by following them; and we have explained to himself, his father, or guardian, the injuries that have been found to follow some special trades more than others (say white lead, needle-grinders, &c.)."

"In this way much good would result. 1st. We should no longer have innocent persons sacrificed, as they now are, by the ignorant cupidity of parents. 2ndly. Those trades that are really injurious would be amended, when the attention of the scientific and benevolent public was directed to them, which must be the case under a system that would bring the great evils of many trades to light. 3rdly. It would also be one means of keeping up an interest in the welfare of boys during the adult age; for it is during the important time of boys leaving school and settling for life, that they most generally fall out of their position in the social fabric."

INCOME-TAX.

From the following report of what took place in the House of Commons on Tuesday, there is evidently some encouragement to petition.

"Mr. HUMÉ said, with reference to the explanation which the noble lord the Secretary for Foreign Affairs gave on Thursday last week, some difference of opinion was entertained as to what were his real intentions on the income-tax. The reports in the papers, from which correct details were generally obtained, differed; and therefore he wished the noble lord would state what really were the intentions of the Government—whether they mean to postpone the income-tax altogether, renewing it now by an act for another year, or, if otherwise it were to be continued, whether any alterations would be made, and what those might be?"

"Lord J. RUSSELL said: I am very glad to have an opportunity of stating what I really did say on the occasion to which my hon. friend alludes. It has been supposed that I stated that the intention of the Government was to propose a renewal of the income-tax, without alterations, for another year. What I said was, that if the Government should have introduced a reform bill in the course of the present year, it would have been necessary to propose a continuance of the income-tax without any alteration for a short period; but, not taking that course, I stated that the Chancellor of the Exchequer would, immediately after Easter, state the intentions of the Government with respect to the income-tax and the budget. I have only further to say, that until that period arrives, and the Chancellor of the Exchequer makes his statement, it is not the intention of the Government to furnish any information on the subject."—*Times*, 16th February.

COURT-MARTIAL ON ASSISTANT-SURGEON JOSEPH EDMUND UMPHELBY. Head-Quarters, Simla, October 28, 1852. At a general court-martial assembled at Fort William, on Saturday, October 2, 1852, Assistant-Surgeon J. E. Umpelby, medical dresser, and attached to H. M. 80th Regiment of Foot, was arraigned on the following charge:—

For conduct disgraceful to the character of an officer and a gentleman, in having, at Calcutta, on July 7th, 1852, subjected himself to the indignity of being publicly kicked by Mr. A. P. Pennefather, a clerk in the office of the Administrator-General, without adopting any sufficient measures, either immediately or for three days, to obtain reparation for such insult.

Finding—Not guilty, and honourably acquitted.

Approved and confirmed,

(Signed) W. M. GOMM,
General Commander-in-Chief, East Indies.

October 18, 1852.

Remarks of His Excellency the Commander-in-Chief. The Commander-in-Chief is glad that he is able fully to approve and confirm the honourable acquittal of Assistant-Surgeon Umpelby of the disgraceful imputation brought against him, and his Excellency trusts that the painful position in which this officer has been placed, will be a lesson to him to be more careful in future in the choice of his associates, and more guarded in his language and behaviour.

HUNTERIAN ORATION. The annual oration in honour of the memory of JOHN HUNTER was delivered in the new theatre of the Royal College of Surgeons, on Monday last, by BRANSHY B. COOPER, Esq. The orator believed it to be his legitimate object, not to express in measured terms the praises of Hunter, which had already been done, but rather to trace the effects of his labours, the real utility of which is becoming more and more apparent. It would seem that the advancement of surgery and the auxiliary sciences since his time had tended to increase his fame. The alleged want of education in Hunter, Mr. Cooper thought, might not be a subject of much regret: for it would perhaps be a question whether, if he had been more highly educated, he would have been able so closely to devote his energies to the prosecution of one great object—the investigation of nature's laws. All his investigations were systematically directed to render anatomy and the kindred sciences subservient to surgery. He was a naturalist in the widest sense of the term; for he saw the necessity of commencing at the lowest link of the chain; hence he investigated in succession the inorganic and organic world, and traced the connexion between minerals, plants, and animals, showing how the three rose one above the other, in regular gradation. The orator then gave a brief outline, illustrated by some of the preparations from the museum, of Hunter's researches and views on the blood, on digestion, on absorption, and on reproduction.

Mr. Cooper then alluded to Messrs. Vincent and Dalrymple, Dr. Pereira, Sir John Webb, Dr. Mantell, and other distinguished members of the profession, who had been removed by death during the past year. In conclusion, he said that the present was a peculiarly fitting occasion for inaugurating the new theatre in which the oration was being delivered; and felicitated the members of the College on the fact, that a large sum of money had been granted by government towards defraying the expenses of completing the building, so as to increase the availability of the Hunterian collection.

THE STATISTICAL SOCIETY. The usual monthly meeting of the members took place on Monday, the 17th January, at the Society's house, St. James's-square, Lord Overstone, the President, in the chair. An excellent and elaborate paper on the Property and Income Tax was read by Mr. Farr, in which it was justly argued, that incomes ought to be taxed according to their nature, and that it was not English love of money, but English love of justice, which had excited so much dissatisfaction with the existing arrangements. Mr. Babbage again stated his well-known views and urged the necessity for an agreement in certain principles before the question could be argued with any prospect of arriving at a satisfactory conclusion. Dr. Guy, Mr. Jellicoe, Mr. Grove, Mr. Venables, Dr. Trueman, Mr. Neison, Mr. Mackenzie, and the Chairman, also took part in the discussion, which was finally adjourned to the next monthly meeting.

FRENCH ACADEMY OF MEDICINE. Dr. Conneau, the first Physician to the Emperor, has declined to occupy the President's Chair of the Academy, which he might *ex officio* lay claim to.

HUGE BOA-CONSTRICTOR AND FAMILY. There lately arrived at Liverpool, in the Arrow, Captain Wyatt, from Para, a huge serpent of the boa genus, respecting which we have received some interesting particulars. The reptile is at least eighteen feet in length, and was caught by some of the natives on the banks of the "mighty Amazon". Before it came into the possession of Captain Wyatt it had satisfied its appetite by swallowing a full-grown goat. On the day the vessel left Para, the captain and crew were surprised to find that the serpent had given birth to thirty-six young ones. The "snakelets" were about two feet each in length, and in six weeks they have only grown about an inch in length. The report of this "birth extraordinary" soon spread at Para, and about one hundred and fifty of the leading gentlemen of the place went on board the Arrow to see the mother and her interesting offspring. In about six days after the birth the mamma devoured twenty-nine pigeons, being the first food she had tasted from the time she had feasted on the goat—a period of about three months. Captain Wyatt has disposed of the boa-constrictor and its progeny to Mr. Edmonds, now the proprietor of one of the travelling menageries of the late Mr. Wombwell, which is at present being exhibited in Manchester. The mother and three of the young ones have been conveyed to that town, but thirty-three of the snakelets have yet to be delivered, dead or alive, to the purchaser. They are at present, in seaman's phrase, adrift in the ship's hold, but will no doubt be recovered as the cargo is discharged. The bite of this snake is not venomous, so that the young wrigglers may easily be captured.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

- *COE, Robert William, Esq., was elected Surgeon to the Bristol General Hospital, on the 10th instant.
- JOHNSON, Henry Charles, Esq., was elected, on the 4th instant, Surgeon to St. George's Hospital, in the room of R. Keate, Esq., resigned.
- NAYLOR, G. F., Esq., has been appointed Assistant-Superintendent of the Wilts County Lunatic Asylum, in the room of Dr. R. F. Foote.
- *POLLOCK, George D., Esq., was elected, on the 4th instant, Assistant-Surgeon to St. George's Hospital.

THE ASSOCIATION MEDICAL JOURNAL is published at its own office every Friday evening.

N.B.—Members of the Association receive the Journal, free by post, as a matter of right. To others, the terms of subscription are—For one year, unstamped, £1:6:0; ditto, stamped, £1:10:4.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. VIII.

LONDON: FRIDAY EVENING, FEBRUARY 25, 1853.

NEW SERIES.

THE UNIVERSITY OF LONDON AND THE PARLIAMENTARY REPRESENTATION OF THE MEDICAL PROFESSION.

In another part of this number will be found a second letter from Dr. SNOW BACK, on the claims of the University of London to elect representatives in Parliament for the Medical Profession. If the question were merely as to the claims of the university itself to be elevated to the rank of a parliamentary constituency, supposing the same privilege to be conceded to elder universities that yet remain unenfranchised, we presume that there could be no dispute about it. On this point, Dr. Beck has fully succeeded in making out a strong case for his *Alma Mater*. He has not indeed shown altogether to our satisfaction that this particular privilege was in the contemplation of those, who advised the granting of a charter to the University of London; or of the legislature, in such acts of Parliaments as have since been passed in ratification of it: but he fairly argues, that a parliamentary representation is a legitimate extension of the principle therein recognised; and he proves by statistics, that the University of London has already attained such a degree of development, and reckons so large a number of graduates, as to place it in a position advantageously to exercise the franchise.

The same statistics, however, go far to show the correctness of Dr. PATERSON's prognostication, that the medical element will not preponderate in this constituency. It appears, from Dr. Beck's own showing, that the graduates in arts of the University of London are to those in medicine, nearly as two to one. Unless there should exist among the former, therefore, a much greater diversity of sentiment than is likely to be the case, we cannot see what chance there is for the medical part of the constituency to turn the election in favour of a candidate pledged to make medical questions and interests his especial study: and even though they should succeed in this, we are very sure that the great body of the profession in England will not stand quietly by, and see their concerns committed to the keeping of a favoured few.

Dr. Beck appears to think that the claims of other universities, which are still unrepresented in Parliament, must be postponed to those of the University of London, because their graduates have no voice in the direction of their affairs: and Mr. Disraeli is quoted, as stating this to be a great obstacle to their obtaining representatives. We cannot see the slightest force in this objection. When a gentleman filling a high official situation suggested, in the House of Commons, that militia-men might be admitted to the exercise of the franchise, it was not thence to be inferred that they were likewise to be privileged to assemble and enact statutes for the government of the regiment, or make grants of money out of the regimental chest. Surely it is very easy to enact that the graduates of a particular university shall have the power of electing members to represent that university in Parliament, without conferring upon them other corporate

rights or privileges. These may be very desirable in themselves, and for the sake of binding more closely together the academic body; but they are obviously not essential to the proper exercise of the franchise.

We have been a good deal surprised to find a gentleman in the position of Dr. Beck, who ought to be well informed on every such point, speaking of the degree of the University of Edinburgh as a mere honorary certificate. This is not correct language to employ of a diploma which entitles its possessor to style himself M.D., which enables him to practise in our most distant possessions, and which constitutes the sole legal qualification of many of our most eminent provincial physicians at home. Whatever privileges, in respect of practice, are enjoyed in England, or elsewhere, by those holding their degrees from the University of London, precisely the same are inherent in the Edinburgh degree, and have been enjoyed, by long prescriptive right, by graduates of that university. In any way to depreciate the one degree, is simply to depreciate the other also; seeing that both enjoy the same legal recognition, and that neither is conferred without satisfactory evidence of the candidate having completed a prescribed course of study at accredited schools of medicine, and a full and rigid examination as to the extent of his medical acquirements.

For the reasons now and formerly (p. 117) stated, we still maintain that the representation of the medical profession in Parliament is urgently demanded; and that the enfranchisement of the University of London, or of any other university, is an entirely different question. In a future number we intend to pursue this subject, commenting at the same time upon the letter of Mr. BEDINGFIELD, printed at p. 178 of this number. In the meantime, we will only remark, that the writer, we fear, greatly overrates the spirit of combination which he assumes to be latent in the medical profession.

THE HISTORY OF MEDICINE AND THE PROGRESS OF MEDICAL DISCOVERY.

THE subject matter of Mr. DAYMAN's excellent letter, published in our last number, has so interested us, that we are led to swerve somewhat from the course we had marked out for ourselves, and to offer a few sentences on the Nature and Progress of Medical Discovery, as it appears by the light of Medical History.

This subject is a wide one, and would have to be discussed in as many leaders as we can afford lines, before its full importance and extent could be recognized.

Two facts, however, in connexion with the subject present themselves before us at this moment; and after stating them separately, we will discuss and prove them together.

First. The history of medicine shows that the progress of medical discovery is slow, and that in every matter connected with the advancement of our art, numbers of minds

have been employed, for long periods of time, in working out that advancement.

Second. Medicine only advances as a part of the great caravan of the universal sciences.

The father of medicine, the great Hippocrates, is not only the first of medical men, but the first and best historical figure to which we can point, while proving the truth of the two statements offered above. In this day it would be simply absurd to say that Hippocrates made, framed, and emitted from his own mind all those medical truths and suggestions, which bear his name and seal.

The contrary, indeed, is well known. For centuries preceding Hippocrates, the vast stores of medical learning which flowed upon the world through him had been accumulating. On the tablets of the Grecian temples, the treatment and signs of diseases had been laid down, line upon line, and precept upon precept. On the lips of the people many a medical proverb hung; and by the gentle hands of friendship, numerous remedial measures were dispensed. Those tablets the father of medicine read, those proverbs he heard, those simple curative measures, which instinct suggested and love applied, he witnessed. Still more, he was surrounded by other philosophic minds, and had been preceded by many such, some of whom had even turned their thoughts to the cure of diseases. He was neither the past, the present, nor the future sage of the wonderful period included in the first two hundred Olympiads. There had been before him, Empedocles, breathing a rude physiology. Alcmaeon had taken to pieces the living machine. Leucippus had dreamt of the atoms of bodies, and had pictured in outline, that theory, the filling up of which in detail, has rendered our own Dalton immortal. This atomic theory was reproclaimed by Democritus, the contemporary and friend of Hippocrates; that laughing philosopher who, before the very eyes of the great physician, opened the bodies of animals, and who is said to have written treatises on plagues, on diet, and on many other medical subjects. Herodotus also was travelling about that time, and was taking much pains to record the manner in which people of foreign lands cured their sick; while Socrates and Plato were not far off, teaching their divine philosophy.

Thus Hippocrates lived in an extraordinary age, amongst wonderful men; and his great merits consist in the fact, that he collected the medical wisdom of his period, wrote it down, and added to it the fruits of his own observations.

Let us take a long stride in the history of the profession, and select another illustration. The name of the immortal Harvey, to whom Mr. Dayman refers, will suit us in every way.

The world is accustomed to speak of Harvey as the discoverer of the circulation of the blood, nor is it altogether incorrect in doing so. But it is the greatest possible mistake to imagine that the whole credit of the discovery is due to this one great man. Harvey, in truth, only completed the discovery; forged the last link in the chain of evidence that was required; and brought a theory to the point of demonstration.

The merest glance at the subject indeed will show that no single mind could have worked out to completion the intricate problem of the circulation of the blood. No; it required a Galen and a Servetus to discover the pulmonic circuit; a Realdus Columbus to throw out the idea of an arterial current; a Fabrizio to show the use of the valves

in the veins, and a Harvey to connect all these discoveries, to grasp all the truths they contained, to make out other truths from nature, and at last to establish the simple beautiful and demonstrable theory with the mention of which his name will be for ever bound.

But more; Harvey was influenced by collateral intellectual agencies. Our colleague Mr. Dayman seizes on this idea with great correctness. In Harvey's days, the spirit of free inquiry had burst into new life. The whole world was vigorously shaking off the fetters which had so oppressed it in body and in soul. The Reformation was established in this country; and the political freedom of the land was being secured by the blood of thousands of noble and generous hearts. Harvey took no part in these struggles, it will be said. He did not: and why did he not? because his whole soul was absorbed in other matters. But there can be no doubt that the stirring events which were going on around him failed not to exert an influence over his mind, and to lend to it not a little of that firm and independent tone which assisted him so importantly in establishing his views, and in fulfilling his great mission. Lastly, Harvey lived in a day when the value of experimental philosophy was being fully recognized and pursued, and when Bacon himself was pouring forth the abundance of his learning and streams of original knowledge.

We will take one more step, and will seize the name of John Hunter, for the purpose of illustrating the views with which we set out. There are many false notions and incorrect estimates in the world, as to the labours of this illustrious man. It is an unfortunate thing, that Hunter despised learning—we had better say *affected* to despise it, for in sober truth no man ever prized it more. It may be that he scoffed at books; but it is well known that he did not under-estimate scientific and learned conversations. It is well known too that his powers of perception and of memory were of the first order, and that he held constant communion with the most competent medical scholars of his day. Thus he was not an ignorant man at all, but a well-informed man, and only differed from other men in the fact, that he obtained his historical knowledge by the ear rather than by the eye. Moreover, the works of Hunter when properly understood, show the extent of his information. No individual could possibly have achieved what he achieved, starting on nothing.

These works also show another important fact, viz., that whenever their author did advance theories which were purely the offspring of his own fertile mind, they were those of his theories least calculated to survive, and to stand against the impartial test of after criticism.

Again, it is quite evident that Hunter, like Harvey and Hippocrates, was influenced much by the spirit of the times in which he moved. The very disregard for learning which he assumed was not peculiar to him, but was possessed by many of that day, not excluding the reigning monarch himself.

Finally, there is every reason to believe that the indomitable energy and independent character of John Hunter were peculiarly intensified by the great mental and physical movements that were going on around him. The music of Handel, the eloquence of Pitt, the labours and military glories of Washington, the discoveries of Black, Priestley, and Franklin, and many other events, all served to fan into fierce flame the energies which started in him.

of the great British surgeon. With so much activity of thought around him, how could his mind sleep? With so much of living action about him, how could his strong hand rest?

But we have gone on already too far, and must with another word conclude.

From the illustrations we have selected, and the remarks made thereupon, we believe we have proved the truth of the statements with which we started. To the selections offered, a hundred others could be added; and if we might pass from our own science into the other sciences, we could demonstrate the truth of our position to an unlimited extent.

It may perhaps be imagined by some readers, that it has been our intention to lessen the fame of the acknowledged leaders of our profession. The reverse is our object. We would not detract in the slightest degree from the glory that is attached to those names to which special reference has been made, or to the names of any other of our illustrious dead. Hippocrates, Harvey, Hunter—to allude to no others—were men first in greatness—were men of true genius; but they were great, they were men of genius, simply because they possessed minds competent to gauge accurately the periods in which they lived; because they personified those periods in themselves, and moved onward with them. Still more, they started where other men had left off, followed out investigations which had been commenced, and did all in their power to complete those things which they took upon themselves to perform. The recognition of these supreme mental qualities is, in our opinion, the highest compliment that can be paid to genius.

In conclusion, what important testimony does this reasoning offer to the value of the study of the history of medical science! Armed with a knowledge of such facts as we have thrown out, the aspirant to true medical fame would know at once the proper means to be pursued in order to reach the goal at which he would arrive; and would not fail to taste eventually the truth of the maxim, "Well begun is half done".

THE SYDENHAM SOCIETY.

WE are well satisfied to see that the last volume issued by the Sydenham Society is a translation from the German of a standard work on Nervous Diseases; for it is one of the most important objects of such a society to supply translations of valuable works, which are not likely to command a remunerating sale under the ordinary circumstances of publication.

The intimate connexion of the mind with the nervous system makes all questions concerning the mental powers of a high practical interest to the scientific physician; and although the physical philosopher may neglect metaphysics (and even pride himself on his ignorance, as people are apt to do, notwithstanding Dr. Johnson's sarcasm), yet no such indifference or contempt can be palliated or excused in a member of our profession who neglects the study of the functions of the brain. For what are metaphysics, but attempts to trace the order and to distinguish the processes of the various functions of the brain? Indeed, all we know of these functions is through metaphysicians, who have laboriously studied the sequences and relations of their own thoughts and feelings, and observed the outward manifestations of mind in others; and who have generalized the results

and reduced them into some sort of system. As the physiology of the lungs is elucidated by the quantitative and the qualitative analysis of the gases inspired and expired, so the physiology of the brain is elucidated by the close analysis of the individual's own thoughts and feelings. To despise the quiet labour of the metaphysician, is as unwise as it would be to laugh at the scales and measures and arithmetical calculations of a Cavendish.

Now, the Germans are, by mental idiosyncrasy, a metaphysical people. One of their newspapers cannot be taken up, without seeing that a considerable amount of metaphysical knowledge is assumed in the general reader. As the only way in which light can be thrown on what is obscure, is by attention, observation, and thought on that subject, so our hopes of the solution of some of the profoundest problems of the brain must naturally be bestowed on an eminently thoughtful nation, who addict themselves especially to that kind of research. Translations, therefore, from the German of works on the subject which Dr. HOLLAND has so well called "mental physiology", are much called for. They will not be remunerative to the general publisher, as readers of such books are comparatively few: but this paucity of readers is no measure of the good which results from the diffusion of knowledge; for all men who are really practical in the true sense, are only so from having appropriated the labours of those who have preceded them; and the truth which has required years of research, may, when embodied in a few words, be used by numbers who know not how they came by it, or who may have regarded the discoverer as merely a scientific man, or as a speculative dreamer.

We trust that the Sydenham Society will continue to supply its annual volumes of *medical classics* for a long series of years. The great support which it has received, and the admirable volumes which it has published, show the excellence of its management, and prove that the scholarship and the medical learning of the present race of physicians are not on the decline. All are interested in the *status* of our profession; and although this must chiefly depend on the character of the mass of its members, yet it is also raised in public estimation by the comparatively few, who laboriously devote those hours to medical science and medical literature, which the majority spend in ease or in amusement. A society such as the Sydenham, which publishes, at a very moderate expense, works of a highly scientific or literary character, must be eminently influential in keeping up the *status* of a learned profession, and therefore richly deserves the countenance of all who wish well to their honourable calling.*

THE INCOME-TAX.

Now that the profession is becoming alive to the importance of uniting in one powerful phalanx against the income-tax injustice, we have good hope of the Chancellor of the Exchequer proposing a more equitable adjustment of this impost, and obtaining the consent of Parliament to such a proposal. Numerous meetings of medical men, we are thankful to learn, have already been held, and others are

* The first volume of Romberg, *On Diseases of the Nervous System*, has already been issued for the subscription of the current year; and a translation of Külliker's *Manual of Microscopic Anatomy* is stated to be in preparation.

announced as about to take place, for the purpose of petitioning both Houses of Parliament.

The Central Council of the Association have determined to assemble the profession residing in the city and county of Worcester, as will be seen by their resolutions published at p. 178; and if any of the Councils of the District Branches have not yet moved in a similar manner, we trust that they will no longer defer following the advice which has been issued from head-quarters. There is absolutely no time left for delay. The voice of the profession, if it is to be effective, must be not only unanimous and earnest, but it must be immediately spoken.

We would repeat the words of Dr. SMITH, published in our last number (p. 157):—"Let the period between this and Easter be employed in getting up influential meetings and numerous signed petitions; and during the recess, when members of Parliament return to the country, let them be waited upon, and urged to help our just cause."

Dr. NANKIVELL's suggestion (p. 178), as to adopting or adapting the form of petition employed by the practitioners of Torquay, may save a good deal of trouble, as that petition is correctly expressed and thoroughly *ad rem*.

NAVAL ASSISTANT-SURGEONS.

In no department of the national service is so much money expended for so little purpose as in the Royal Navy. Ships are built and immediately taken to pieces in the most wanton way, just as if the main object of the dockyard authorities was to use up a certain amount of public money: at all events, so it is, that the value which the country receives in the shape of effective war ships, is very far from proportionate to the treasure absorbed by the shipwrights. Then again, with the proverbial obstinacy of incompetence and adherence to routine, a British admiral rarely enters upon his office till he has become physically and mentally unfitted by old age for his high and responsible command. The common sailors too are so badly treated, that the navy of the United States, and our own mercantile navy, completely absorb the best seamen; and recruiting for the royal navy, in place of being, as it ought to be, very easy, is always extremely difficult; so difficult indeed that we constantly read in the newspapers of ships being detained in harbour for want of men.

The surgical department, which ought to be formed from the very *élite* of the surgical talent of the nation, is systematically insulted, the assistant-surgeons being precluded from all opportunities of study and self-instruction, by being denied cabins and being obliged to spend their time amid the puerilities, tricks, and noise of the midshipmen. As Mr. HUME well remarked on Monday night in the House of Commons, when the navy estimates were under discussion:—"The question was whether the navy ought not to obtain as able and efficient medical assistance as the army. For his own part he could see no reason why both officers and men in the navy should not receive the best medical talent that was to be had, which, however, was impossible so long as the assistant-surgeons were treated as at present." As a question concerning the honour and status of our profession, the ill-treatment of the naval assistant-surgeons is one of vast importance, but as regards the public its bearings are of greater magnitude. How many lives may be saved after action, and how much disease and pestilence avoided in unhealthy climates, by a talented medical staff! but how can

such ever be hoped for in the royal navy till those who enter the service as assistant-surgeons are treated as gentlemen and men of science? It appears to us that the whimsical carpentry of our dockyards, the senility of our admirals, and the way in which talented surgeons are discouraged from accepting commissions in the royal navy, present topics for discussion of far higher moment than any which are involved in mere party disputes; and we feel assured that the day is not far distant when patriot-statesmen of all political parties will cooperate on behalf of the nation, in removing the abuses to which we have now adverted. Here, we may remark, is one of the many mixed questions in which medical members of Parliament might speak with authority, and by so doing serve their profession and their country.*

We must not leave this subject without stating our belief that, among the superior officers of the navy, the feeling is decidedly in favour of a wiser policy being adopted towards the assistant-surgeons. It is with much pleasure that we copy the following from the *Times* of February 16th:—

"*Sheerness, 14th Feb.* The *Espiègle*, 12, Commander, George Hancock. Under the present Admiralty regulations for the accommodation of officers, no provision has been made for the Assistant-Surgeon appointed. Captain Hancock has given up one of his own cabins for the entire use of the Assistant-Surgeon, otherwise he must have been without a cabin for his personal comfort."

The kindness and good sense of Captain Hancock convey a severe censure to the parliamentary partisans of Admiralty routine.

ORIGINAL COMMUNICATIONS.

INFLUENCE OF NOXIOUS EFFLUVIA ON THE ORIGIN AND PROPAGATION OF EPIDEMIC DISEASES.

By R. D. GRAINGER, Esq., Lecturer on Physiology at St. Thomas's Hospital.

(Read before the Epidemiological Society.)

HAVING in the course of my official inquiries received, through the kindness of my professional brethren, a large amount of valuable evidence illustrative of the noxious influence of overcrowding, defective ventilation, etc., I have thought that it might not be unprofitable if some of the facts which have fallen under my observation, both as regards the causation of, and the exemption from epidemic disease, were laid before the profession.

Within the limits of this paper, it will be possible only to make a selection of the conditions affecting the health of large masses of the people; I therefore propose to direct attention to two of the many deleterious agents prevalent in populous localities: namely, to human effluvia, and to the emanations generated by privies and cesspools. But before entering upon the more immediate subject matter here traced out, a few remarks may be offered on the predisposing causes of epidemic disease, and especially on the circumstances which explain the vast influence they exert in its diffusion.† The extended inquiries of late years have abundantly shown, that the same deleterious agents operate as predisposing causes in regard to the whole class of zymotic diseases; that what will develop the exciting or efficient cause of fever, will also develop scarlatina, small-pox, diarrhoea, or cholera. So certain and notorious is this

* At p. 180 will be found an account of what took place on Monday night in the House of Commons with reference to the present treatment of naval assistant-surgeons.

† This subject is ably discussed by Dr. Carpenter, in a valuable paper on the Predisposing Causes of Epidemics.—*British and Foreign Medical Review*, January 1869, p. 160.

to those who practise among the poor, that before the outbreak of any epidemic, knowing where the predisposing causes are rife, they could foretell the precise localities where it would occur; or even name the alley, or point to the exact house which would suffer.

Another circumstance which extends the influence of these causes is that, if concentrated, any one of the number—overcrowding, privy effluvia, foul evaporations—will often suffice to induce any of the principal members of the zymotic class, according as the exciting cause of one or other of the number happens to be present.

The only other point to which I would allude, is that these predisposing causes have not only this wide range in multiplying the number of attacks, but they invariably, as the rule, give intensity to every form of epidemic disease, and thus increase enormously the general mortality.

These and other considerations have long induced me to conclude that, in regard to zymotic affections, the predisposing are infinitely more important than what are called the immediate or exciting causes. In regard to low fevers, for example, it is certain that its efficient cause—the *materia morbi*—is never absent from London and other large towns; and yet it is rarely—many would say never—developed unless there be superadded to it some predisposing cause. So true is this, that we not only daily see in the metropolis and elsewhere, hundreds and thousands of persons living in the front streets exempt, as to the rule, from typhoid fever, whilst the inhabitants of the wretched courts behind are scarcely ever free from it; but if, by chance, a given number of persons are planted in the very centre of an epidemic district, but freed from the recognised predisposing causes of zymotic affection, they also, as the rule, will still escape. At the conclusion of this paper, some marked examples of such exemptions, both in regard to cholera and fever, will be adduced. It is facts like these that hold out so much encouragement for sanitary ameliorations, by which it may be reasonably anticipated that in the ratio in which these predisposing causes are reduced as to number and intensity, epidemic diseases, wanting one of the elements necessary to their development, will be diminished. With these prefatory remarks, I proceed to the subjects selected for consideration.

I. INFLUENCE OF HUMAN EFFLUVIA.

According to my own opportunities of observation, the most injurious of all the causes operating in the diffusion of epidemic diseases, are the effluvia proceeding from the human body, and especially from the lungs and the skin. The special deleterious agent consists of the effete and, as it has been proved experimentally, highly putrescent organic matter, mingled with the expired air. That it is, when reintroduced into the living body, liable to be highly injurious, may be inferred from the fact of the careful provision made by nature for its incessant elimination from the system. That it is small in amount, is no objection to the intensity of its action; for to the physiologist it is well known that a minute quantity of a powerful agent—the putrid matter introduced on the point of a needle in the inspection of a dead body—a single drop of concentrated prussic acid placed in the mouth of an animal—is sufficient to destroy life. It is in overcrowded bed-rooms, in unventilated schools, workhouse dormitories, etc., that this effete matter taints the air, and, entering the blood, poisons the system. That the remarkable diminution in the amount of carbonic acid evolved from the lungs, where persons, as in crowded and unventilated apartments, breathe an impure atmosphere, acts in such cases injuriously, admits of no doubt; but the evil, *quod* the development of fever, scarlatina, cholera, and so forth, depends on the organic, and not on the chemical products of respiration. As one indication of this, it may be explained that it is possible, under certain circumstances, to observe the action of the former when separated from the latter. As soon as the expired air quits the body, the matters of which it consists have a tendency to separate; and as regards the two substances under consideration, the carbonic acid mixes with the at-

mosphere on the principle of diffusion; whilst the animal excretion, no longer held in solution by the colder external air, is deposited, and particularly clings to woollen articles, as bedding and clothes, which last, as it is well known to medical men, clergy, and others, will often retain for hours, or even longer, a foul smell from this cause alone. When this matter, from neglect, is allowed to accumulate, it will affect the health. An instance of this was mentioned to me by the surgeon of a large pauper school, where the health of the boys was decidedly improved by substituting, for the usual dress, clothes capable of being readily washed.

It is, however, familiar to all practitioners, that human effluvia especially exhibit their poisonous influence when either multitudes of human beings are crowded together, or where a smaller number are placed in confined and unventilated sleeping places. Many instances of the influence thus excited on all kinds of epidemic disease have come under my notice; but only a few illustrative examples can here be adduced. In making these selections, it will be my object to present instances which, as far as possible, display the operation of some one individual agent; for when, as usually happens among the poor, a multitude of unfavourable conditions are present, it is extremely difficult to define and demonstrate the deleterious agency of each.

The following case illustrates the effects of overcrowding, in respect to cholera. During the epidemic of 1849, the inmates of a reformatory establishment for young women suffered intensely from the pestilence; 40, out of a total of 96, being attacked, and 15, or rather more than 15 per cent., dying. Now, these poor sufferers were previously in perfect health: they were well fed, well clothed, and, in short, carefully tended; but the dormitories were low, and much crowded; the windows, for the sake of seclusion, were partly blocked up, which greatly interfered with the ventilation. After a careful examination, I could detect no other cause than this for the sudden outbreak, occurring at a period when there was little cholera in the neighbourhood.

As regards the influence of overcrowding on the development of low fever, I may appeal to the experience of every medical practitioner whose duties call him much among the poor. It matters not whether we speak of the closely-packed common lodging-house; of rows of houses built back to back; of the small, unventilated, and often single sleeping apartment of the mechanic; or of the ill-built cottages in rural districts, with their one bed-room, overhanging thatch, and small lattice; wherever, either from numbers or the want of ventilation, we have the foetid, sickening air, generated by human effluvia, there assuredly we shall find fever. Although observed especially among the poor, fever, as it occurs in this country, is not, however, essentially dependent on poverty and destitution: want may, indeed, aggravate the evil, and actual famine (as we unhappily saw a few years ago in Ireland, and in the inhabitants of Ireland who fled to the manufacturing districts of England) may give immense development to typhus; but that persons well fed, living in comfort, and in strong health, may suffer severely from low fever, is shown by a large experience.

One of the best illustrations, perhaps, is furnished by the sailors belonging to the collier vessels frequenting the Thames. These men, as a body, are in the prime of life, robust, and well fed; but, as I found by examining many of these vessels, the place where they sleep, the fore-castle, is excessively small and confined; with this serious additional evil, that, as the hatchway is usually flush with the deck, it becomes necessary, whenever there is much sea, to close it down, when the unfortunate sailors must be without any window, as if shut up in a close box. When, too, the vessels come to London, as only one man is required to keep watch at night, all the sailors are crowded at the same time into their closely packed berths. Some years ago, the attention of Mr. Busk, the distinguished surgeon of the Seamen's Hospital Ship, was attracted to the large number of typhus cases which were admitted, amounting in 1841 to 147, and in 1842 to 167; and to the fact that, of all the vessels in the Thames, the colliers were most subject to

fever. In investigating this question, I could detect no other cause than the polluted air which these men must have breathed in the confined fore-castle. That there is nothing connected with a sailor's mode of life to expose him to typhus, is proved by the experience of well managed vessels; and, as one among the many proofs which might be adduced, I may mention, that Mr. Clark, who made ten voyages to India as surgeon in Messrs. Green's fine vessels, never had a single case of typhus.

To those who are practically acquainted with the poorer parts of populous towns, it would be needless to point out that the common lodging-houses, and especially those occupied by the Irish, inflict an almost incredible amount of evil on the community: they are the common foci of all epidemic diseases; they frequently are the means of introducing small-pox into the locality where they are situated; and they are a never-failing source of expenditure to the parochial authorities. Although other sources of sickness may prevail, filth, neglect, and destitution—this last, however, by no means so often as supposed—the one prevailing evil and special characteristic is enormous overcrowding, carried to an extent which those unacquainted with the subject can scarcely, even in idea, realize. In the valuable recent report of Captain Hay, the Commissioner of Police appointed to superintend the carrying out of the Common Lodging-House Act in the metropolis, and to whom so much credit is due for carrying into operation a difficult and novel measure, some remarkable illustrations are given. In one eight-roomed house, one hundred and three persons, the population of a hamlet, were herded together; in one room, 14 feet 6 inches square, thirty-seven people were found lying huddled together on the floor. In many of these instances, the space for each inmate could not have been more than forty cubic feet; whilst the lowest amount required for health in a sleeping room is 500 cubic feet, or twelve times the amount.

My own experience corroborates these statements of Capt. Hay. On entering some of these deplorable places, I have found every possible space occupied by men, women, and children; and an atmosphere so fetid as to be almost overpowering to a stranger; causing, indeed, in some instances, nausea and actual vomiting.

That persons habitually breathing an air thus polluted by poisonous exhalations, should become the victims of zymotic disease, can excite no surprise. As to low fever, the amount is enormous. I had occasion, two years since, to examine some of the courts in Gray's Inn Lane; and in one of them was an Irish lodging-house, in which alone twenty cases of fever had occurred in two months.* Another and more marked instance was lately mentioned to me at Leeds, in which seventeen cases of typhoid fever were, about two years since, received in one week at the House of Recovery, from two of these lodging houses; the cost to the parish for this week's work being £50.

It is satisfactory to learn that the Act of Parliament for regulating common lodging houses, for which the community is indebted to the Earl of Shaftesbury, has been extensively put into operation in London and the provinces, with the best results, both moral and physical. At Portsmouth, where there are not fewer than five hundred of these dwellings, I was informed by Dr. Slight, the Inspector, and by Mr. Piercy, the medical officer of the district, that in those houses placed under regulation, there had been a general reduction of disease, especially of fever; and it was particularly stated, that no second case of fever had occurred; whereas, in ordinary circumstances, as shown above, where typhus once breaks out, the rule is that it spreads among the inmates, many of whom often fall victims to the pestilence.

[To be continued.]

* Report on the present state of certain parts of the Metropolis, and on the Model Lodging-Houses of London. By R. D. Grainger, Esq. Ordered to be printed by the House of Commons, 1851.

MORTIFICATION EXTENDING FROM THE HEAD OF THE FIBULA TO THE CREST OF THE ILIUM. RECOVERY.

By RICHARD ALFORD, M.R.C.S.

CASE. On the 16th of June, 1852, W. B., a carpenter, aged 61, knelt accidentally on a nail when about to clinch the nails of a door. The puncture was three-fourths of an inch deep, just below the right patella; but gave him very little inconvenience at the time. He continued his work until the 19th; and on this evening walked eleven miles. His wife now fomented and poulticed the knee, which had become inflamed and painful: and on the 21st, medical advice was procured and leeches, etc., applied.

I first saw him on June 25th, and found an abscess over the ligamentum patellæ; and, on lancing it, about half a teacupful of tolerably healthy pus escaped. Outside the knee and thigh gangrene had commenced, and extended upwards to about the length of the hand; and the outside of the thigh was red and swelled up to the hip: the inside of the thigh and the leg below the knee were not affected. My patient's general appearance was by no means good; his powers seemed sinking, and altogether the case was unpromising. I ordered him to have as much port wine as he could take, with light nourishment, beef-tea, eggs, etc.; and a mixture of quina, opium, and dilute sulphuric acid, with an occasional alterative aperient pill. A lotion of chlorinated soda was applied to the gangrenous part, and covered with linseed meal and barm poultice. A poultice was also applied over the abscess; and six leeches to the upper and outside of the thigh. For the next day, a cooling lotion of acetate of lead to this part was prescribed.

July 1st. The mortification was creeping up the thigh, and redness was extending across the loins. The case appeared hopeless; the patient was extremely prostrated, and took a bottle of wine daily, but very little else.

July 12th. To my great surprise, my patient kept up, and threw off the dead parts. Sphacelus had extended to the crest of the ilium; a spot of the size of a crown piece had turned black opposite the sacrum, and redness and swelling extended up to the false ribs. He had a pint of port wine and a quart of porter daily, and continued his mixture.

July 16th. I procured a horse-shoe water cushion* for him, from which he experienced great comfort. The ulcer outside the thigh extended from the head of the fibula to rather beyond the crest of the ilium, and was two feet long and eight inches wide at the top, its widest point, the average width being about six inches. Mortification had penetrated deeply in the fleshy part of the thigh at some points.

Aug. 6th. The poultice was omitted, and the lotion of chlorinated soda was continued, and covered with gutta percha sheeting. The dead parts had all come away; the back was sound, and the general health vastly improved. The abscess over the ligamentum patellæ still discharged, and another had formed and burst over the upper end of the fibula, a little below the ulcer. The leg was somewhat swollen, but the inside of the thigh was quite healthy.

Aug. 17th. Water dressing had been used a few days; the granulations were flabby, large, and disposed to bleed; the discharge was very profuse. Lotion of sulphate of zinc was now used, at first weak, but gradually increased in strength, and nitrate of silver was occasionally applied to the edges of the ulcer. From this time the healing process rapidly went on, and his general health improved.

Sept. 4th. The stimulants had been gradually decreased, and were now altogether omitted. A mild saline was ordered to be taken occasionally to relieve head symptoms, resulting doubtless from the decrease of the discharged blood.

* No. 6 of Mr. Hooper's cushion.

Sept. 25th. On first getting down stairs, he suffered a good deal from swelling of both legs.

Nov. 19th. The ulcer was now reduced to a mere line a few inches long, and half-an-inch wide. He complained of rheumatic pains in his right shoulder from exposure to a draught; and of cough, in common with the other members of his family. The knee-joint admitted of very slight motion. The abscesses were healed. The legs were now swelled very slightly. He was ordered to take compound squill pill three times a day.

Dec. 28th. The sore was quite healed: he still suffered from rheumatism, etc., but was gaining flesh. The motion at the knee was improving, but he could not yet bend it to a right angle with the thigh. The cicatrix seemed healthy, but he occasionally felt a shooting pain in its upper part at the bend of the thigh, where it seemed a little chafed by his flannel, and a truss which he wore for a left inguinal hernia. This part was now covered with cotton wadding, and the whole daily washed with rain water, and slightly anointed with fresh lard.

REMARKS. Amputation was out of the question, from the extent of the inflammation on my first visit. I had therefore to trust to stimulants, and I consider that my patient owed his life to the port wine, on which he almost entirely lived for the first ten days or fortnight of my attendance on him.

He assures me that the nail penetrated fully three-quarters of an inch; and it must have entered the joint; yet the probability is, that if he had rested for a few days at first he would have felt nothing more of it.

There is some thickening and tenderness around the punctured spot; but the patella is freely moveable, and the difficulty of bending the joint lessens; it moves freely up to about an obtuse angle with the thigh. He walked to church, Jan. 31st, with one crutch and a stick, and found from the fit of his breeches, put on for the first time on that day, that the knee was larger than the other. There is no thickening above the patella. The length of the cicatrix is one foot seven inches; its greatest width at the bend of the thigh is four inches, average width about three inches, in some parts scarcely two. It has receded from the crest of the ilium three inches; the ulcer extended rather beyond this point.

Tewkesbury, Gloucestershire, February 1853.

SUGAR IN URINE NOT ALWAYS INDICATIVE OF DIABETES.

By HENRY JOHNSON, M.D., Physician to the Salop Infirmary.

ALTHOUGH a saccharine state of the urine be the pathognomonic sign of diabetes, we are not too hastily to conclude that this very serious disease exists, whenever we find sugar in the urine.

CASE I. A clergyman, aged 60, had common catarrh, for which he took proper remedies, and, on his return from Aberystwith, came to consult me.

In the course of conversation with him, I found that he was in the daily habit of taking at his breakfast large quantities of *sweet-meats*, or preserved fruits, for the purpose of keeping his bowels regular. He also complained of frequent calls to make water, and it was this circumstance alone that induced me to get an opportunity of testing the urine. It was pale, and of the specific gravity of 1040. Treated with liquor potassæ, according to Moore's test, it yielded a deep reddish brown colour, and it fermented freely with yeast.

Here, therefore, there was the characteristic symptom of diabetes, "*saccharine urine*" but, no rational sign of the disease, except frequent calls to pass water. It was *temporary or occasional diabetes*, and, I believe, easily removed by avoiding in future the abuse of sweets. The patient passed from under my own immediate observation, and I had not another opportunity of testing his urine. But I have

reason to believe that it was so examined, and found to be no longer saccharine. He died about a year after, of disease unconnected with diabetes.

CASE II. Mr. A. B., aged 58, a very tall, portly man, of bilious temperament, ample abdomen, and accustomed to very generous living, sent to me on account of a very severe pain in the hypochondriac and epigastric regions, to which he was very subject. There was no febrile excitement, but he had loss of appetite, a furred tongue, and constipated bowels. As he had formerly, (as I was told) passed a gall-stone, it was suspected that he might be again suffering from this cause, but no such concretion made its appearance. I considered it a case of severe flatulent colic. He had certainly not a single symptom of diabetes; however, to my great surprise, on examining the urine, I found it pale, of high specific gravity (1048), and it contained sugar, as evinced by Moore's test, and that of fermentation with yeast.

The colicky pains soon yielded to appropriate treatment, and the patient required no particular regimen on account of the state of the urine.

It is now two years since the above case occurred. The gentleman alluded to is now performing the active duties of life, and is apparently well. But I have lately obtained an opportunity of again testing his urine, and found it still saccharine.

I consider such cases as the foregoing very valuable, as teaching us caution in our diagnosis and prognosis; for without such proofs that a saccharine state of the urine may be temporary, or normal, we might form a more unfavourable opinion than the circumstances justified.

From what I have observed in another case, I suspect that in feeble states of the digestive power of the stomach, cane sugar is converted into grape or diabetic sugar, and that this, if not further changed in the animal economy, passes into the blood, and is voided by the kidneys, even in apparent health.

The preceding observations were written some time since. I have this day been reading with much pleasure M. Dechambre's paper, "*On the Habitual Presence of Sugar in the Urine of Old People*."

We have here, therefore, two independent series of facts, M. Dechambre's experiments, and my cases, materially illustrating and confirming each other. The former make us acquainted with a curious physiological law, the latter teach a useful practical lesson. M. Dechambre thinks that the presence of sugar in the urine of old people, arises from the impeded action of the lungs, incident to old age, according to the theory of M. Alvaro Reynoso. The subjects of my cases were not "*old persons*"; but, perhaps, the function of the lungs in them might be relatively less active than natural from want of active exercise.

Some very curious experiments have been performed by Dr. Claude Bernard upon the sources of sugar in the animal economy. He concludes—1. That sugar is a normal ingredient in the blood and liver of animals. 2. That the formation of sugar takes place in the liver, independent of the ingestion of saccharine or feculent food.

I have repeated some of Dr. Bernard's experiments. He obtained sugar from the liver and blood of dogs and rabbits. I have found it in the liver, blood, and urine of sheep, slaughtered for the market; hence it appears that the urine of sheep, like that of M. Dechambre's "*old people*", normally contains sugar; and that in fact sheep are naturally diabetic!

Although sugar was detected by Mr. McGregor in the healthy stomach,† I am not aware that it has been discovered in the healthy human liver; and in the only instance in which I have had an opportunity of trying the experiment, I failed to find it.

BIBLIOGRAPHICAL NOTICES.

ON RHEUMATISM, RHEUMATIC GOUT, AND SCIATICA: their Pathology, Symptoms, and Treatment. By HENRY WILLIAM FULLER, M.D. Cantab. Octavo, pp. 403. London: 1853.

IN the preface to this useful book, we find its author remarking that he had proposed to himself, on commencing his labours, to give, in the form of a preliminary chapter, "a faithful record of all that has been ascertained of the history of rheumatism; and by reference to the facts thus proved and established, to show how conflicting opinions may be reconciled, and the pathology and treatment of the disease elucidated". Without stopping to state the somewhat unsatisfactory reasons which induced Dr. FULLER to change his original plans, we at once express our regret that his first excellent intentions have not been carried out: and the more so, because we believe that the chief faults of his volume are a scantiness of historical matter, and an occasional slight degree of inaccuracy in such historical details as have been introduced. Before we proceed further, we have one more fault to find with Dr. Fuller's book, a fault which relates to its literary construction rather than to its matter. We allude to the extraordinary number of foot-notes with which almost every page is encumbered. These notes render the reading of the book absolutely painful in some parts. It matters not how interesting the text may be, or how difficult; for difficult, easy, or interesting, the same obtains; the eye is everlastingly drawn from the leading matter to the contemplation of a significant, but sometimes misplaced foot-note; and the mind is wearied by these constant rockings, as speedily as the body is tired by being drawn through a pleasing tract of country in a carriage without springs.

Taken as a whole, however, we have just reason to admire Dr. Fuller's labours. Each page of the volume shows the author to be an earnest, observant, and accomplished physician. As we proceed with him on his journey, sometimes abreast, and sometimes in his rear, we listen with pleasure to his descriptions, and observe with delight the new lines of thought to which he directs attention.

The volume contains thirteen chapters. The first is "Introductory"; the second "On the Rheumatic Diathesis, and the Causes which influence its Development"; the third, "On the Seat of Rheumatism, and the Classification of its different Varieties"; the fourth, "On Rheumatic Fever"; the fifth, "On the Treatment of Acute Rheumatism, or Rheumatic Fever"; the sixth, "On the Causes of Rheumatic Affection of the Heart"; the seventh, "On Rheumatic Inflammation of the Heart—its Pathological Effects—its Symptoms, Progress, and Terminations"; the eighth, "On the Treatment of Rheumatic Inflammation of the Heart"; the ninth, "On the Statistics of Heart Disease in connexion with Rheumatism"; the tenth, "On Affections of the Brain, Inflammations of the Lungs and Pleura, and Disorganization of the Joints, as Complications and Consequences of Acute Rheumatism"; the eleventh, "On Rheumatic Gout"; the twelfth, "On Chronic Rheumatism"; the thirteenth, "On Sciatica, and other forms of Neuralgic Rheumatism".

Here is subject matter enough certainly; and when we inform our readers, that every topic named above is dealt with in a thoughtful and philosophic manner, they will best form an appreciation of the value of Dr. Fuller's present contribution to medical literature.

We remark, almost incidentally, that our author is always striving to find rational and physiological reasons for all that he advances. It is evident, however, that his mind is more at home at the bedside than in the experiment-room or in the laboratory; and although his physiological reasonings are always creditable, they are invariably the weaker and least original parts of his production, and contrast strikingly with his manner of describing the symptoms

and effects of diseases, and other matters of practical importance.

In continuance of this review, we shall select for observation, the fourth, fifth, tenth, and thirteenth chapters of the volume; strongly advising every one interested in the subject of rheumatism, to make up for our deficiencies of reference by reading the book itself, from its alpha to its omega.

Here, from chapter the fourth, is Dr. Fuller's account of what has been absurdly called the *Metastasis of Rheumatic Inflammation* :—

"A remarkable feature of the articular inflammation, is its migratory nature. In the course of a few days—nay, sometimes within a very few hours, the enemy begins to shift his quarters, and joint after joint undergoes, in turn, the infliction of his terrible visitation. The knee which to-day is red and swollen, may to-morrow present no trace of mischief, while the wrists, the elbows, the ankles, or the knuckles, which have been hitherto free from pain, may, in a few hours, become the seat of inflammation. Moreover, after evacuating its first position, and invading several joints successively, the inflammation not unfrequently commences in its old quarters, and the parts go through the same series of changes to which they had been previously subjected. In some instances, however, the parts first affected remain so throughout the attack; and it will be observed, that the obstinacy and fixidity of the inflammation very generally vary in an inverse proportion to the number of the joints implicated." (P. 6.)

We must find room for Dr. Fuller's observations on the effects of those profuse sweatings which attend rheumatic fever.

Dr. Fuller recognizes two kinds of profuse perspiration in these cases. The one kind of perspiration occurs in acute cases "in the natural course of the disease", and is the means by which enormous acid secretions, especially lactic acid, (the *materies morbi* of our author,) are carried out of the system. These perspirations are highly useful. The second variety obtains, in debilitated cachectic states of the constitution, after the incautious use of the vapour bath, or of depletion carried to an unwarrantable extent, or sometimes towards the close of protracted rheumatic cases.

"Such perspirations are useless, wasting, and enfeebling; though profuse, they emit but little of the characteristic odour. They may be somewhat acid, but not highly so, as before. They are not attended by the same heat of skin, by the same full and bounding pulse, nor by an equally loaded state of urine; but, on the contrary, are accompanied by a soddened state of skin, by a soft, weak, irritable pulse, and not unfrequently by an eruption of sudamina." (P. 64.)

The distinction here given is true to nature, and ought, as a matter of course, to influence treatment in an important degree.

Toward the close of this interesting chapter, the complications of acute rheumatism are ably and pithily introduced. Inflammations of the lungs and pleura, of the sclerotic coat of the eye, of the brain and its membranes, and of the heart and its membranes, are noted down by our author as such complications. He also includes in the same category "active maniacal delirium, *sympathetic* of inflammation of the heart and lungs, or of the vitiated condition of the circulating fluid". We wish he had not made use of the absurd word which we honour with italics, but do not care to repeat.

The fifth chapter refers to the treatment of rheumatic fever, and is more useful in showing the inefficiency of the various modes of medical treatment for the cure of the disease, than in suggesting any decided improvement in practice. Blood-letting is considered objectionable, and an opinion is given that "if a predisposition to cardiac inflammation be not engendered by copious and repeated blood-letting, still convalescence is retarded, the patient weakened, and rendered liable to frequent relapses". A part at least of these ideas was held by the illustrious Cullen, whose remarks, "that profuse bleedings produce a slow recovery, and if not absolutely effectual, are ready to produce chronic rheumatism."

Dr. Fuller next passes on to consider the effects of purgative medicines in acute rheumatism. We observe that he speaks of this form of treatment as of modern introduction into practice; and although we dissent from him altogether on this point, we entirely agree with him as to the injudiciousness of giving continued doses of powerful purgatives in acute rheumatic disease.

On the use of opium in rheumatic fever, the writer thus observes :—

"Therefore, whilst I join issue with those who would treat acute rheumatism by opium alone, I admit most freely the advantages of its employment in conjunction with other remedies." (P. 89.)

Dr. Fuller's remarks on the employment of mercury in acute rheumatism are very decided; and though some what contrary to common opinion, we suspect that they are correct. Speaking of the administration of mercury in combination with opium, so as to produce salivation, he observes :—

"In my opinion, however, this practice is not only unnecessary, but decidedly prejudicial to the well-being and safety of the patient. When given so as to affect the mouth, mercury proves exceedingly depressing, and is sometimes productive of evil consequences, which may be felt for weeks, months, or even years. Moreover, it exerts no perceptible influence over the rheumatic poison, nor does it assist in preventing the access of cardiac inflammation."

In another sentence he says :—

"Moreover, pericarditis and endocarditis supervene as readily whilst the patient is under the influence of mercury, as when that drug has not been administered; and when such is the case, we lose the most valuable property of mercury, namely, that of limiting the effusion of lymph on the inflamed surfaces of the heart." (P. 92.)

After expressing his doubts of the value of tartar emetic in acute rheumatism, our author dwells on the employment of cinchona bark in the treatment of this disease, and speaks most unfavourably of its employment in the early stages of the disorder, as recommended by Fordyce and Haygarth. In the later stages of the disease, however, when the urine has cleared, or has dropped its sediment, the pulse has become soft, and the skin moist, soft, and clean, he employs the bark, or quinine, with advantage. There is not space for us to follow Dr. Fuller in his remarks on the employment of colchicum, guaiacum, nitrate of potash, and lemon-juice, in the treatment of rheumatism. They all fall more or less under his criticism; and one of his remarks on the effects of lemon-juice has been so thoroughly verified in our own practice on numerous occasions, that we give the passage as it stands :—

"I have watched the exhibition of lemon-juice in twenty-two patients, and although in several it produced much depression; in some, gripping pains in the abdomen; and in one gave rise to diarrhoea, accompanied by a copious discharge of blood from the bowels, yet in three patients only did it appear to afford relief, or to hasten recovery." (P. 102.)

The class of cases in which lemon-juice is useful has yet to be pointed out: and it also remains to be determined, whether it has any advantages which other medicines do not possess in rheumatism.

At page 105, we arrive at Dr. Fuller's own line of treatment, which

"Is made up of alkalies and the neutral salts, with colchicum, calomel, and opium. Sometimes a little antimony is added, sometimes the aid of purgatives is had recourse to, and occasionally, though rarely, I deem it expedient to premise a moderate blood-letting. Baths are never employed if the skin is acting freely; but if, instead of being bathed in perspiration, it remains dry and hot, and burning, I then endeavour to stimulate its action by means of the vapour or hot air bath."

Dr. Fuller's great saline remedy is the potassio-tartrate of soda; and he also is fond of applying a warm alkaline and opiate solution to the inflamed joints, by way of fomentation.

From the above remarks, we think that our readers will agree with us in repeating, that the excellence of Dr.

Fuller's treatment of rheumatism does not consist in its being strikingly original. It is simply a careful and judicious mode of practice, and differs only from the practice ordinarily employed in inclining more to the philosophy implied in the adage :

"Our Doctor is a man of skill;
If he does you no good, he does you no ill."

Dr. Fuller concludes this chapter on treatment with the records of six cases, which are reported in accordance with the present mode of making such practical references. The progress of each case is given from day to day, and the medicines prescribed are noted down in the same orderly manner; the most scrupulous attention being paid, also, to the writing of the formulæ employed. We are ourselves no admirers of the system of introducing prescriptions into scientific books, and are particularly annoyed at the mysterious and cabalistic manner in which modern physicians are content to express their directions on paper. If, however, such prescriptions are to be thrust on the reader's notice, it is at least right that they should be done well, and with some degree of deference to the Latin grammar—a deference which Dr. Fuller really pays.

We now pass on to the tenth and best chapter of this instructive book. Our notices must necessarily be very brief.

Speaking of cerebral disturbance as a complication of rheumatism, the author happily omits to make use of many of those meaningless terms which occur in the works of other writers, whenever the manifestations of the mind are referred to. Even the word "sympathy" has now no mention, and we are quite delighted to follow Dr. Fuller, as, gauging with discriminating eye the subject before him, and discerning in the humoral pathology the key to those mental derangements which often accompany acute bodily diseases, he dares to emancipate himself from every fanciful and metaphysical conceit, and thus to write :

"Thus, then, it would appear that in all cases in which cerebral disturbance presents itself during the course of acute rheumatism, the altered condition of the blood is its primary or proximate cause." (P. 286.)

The latter part of this chapter refers to pulmonary disorders as complications of rheumatism, and to disorganization of the joints as a consequence of the same disease. Our readers must, however, remain satisfied with this brief notice of these important subjects.

We conclude with a word or two on the last chapter, which treats of neuralgic rheumatism. In this section of his subject, Dr. Fuller shows a large amount of practical information. He dwells with great ability on the necessity of attending to the digestive organs in neuralgic cases; and is an advocate for the employment of soothing remedies, such as opium, belladonna, henbane, conium, stramonium, aconite, and veratris. He also treats, with some degree of minuteness, on the special value of each of these medicinal substances.

And now, expressing our admiration of the easy, grammatical, and scholarly style in which his book is written, we take our leave of Dr. Fuller, highly gratified with the instructive communion we have held with him, and looking forward with hope to a repetition of that communion.

PRACTICAL OBSERVATIONS ON DISEASES OF THE LUNGS AND HEART. By ARCHIBALD BILLING, M.D., F.R.S. 8vo., pp. 138. London: 1852.

THIS is a vigorous and somewhat dogmatic book, evidently written for the author's satisfaction, but nevertheless well calculated to prove suggestive and refreshing to those who are already tolerably conversant with the subjects of which it treats.

Dr. BILLING is endowed with no ordinary powers as a writer; he possesses a clear and logical intellect, in combination with an irritable, energetic, self-relying temperament. His evident tendency is to escape, as quickly as possible, from detail—to grasp essentials—to illustrate gene-

ral principles—to disentangle and to simplify. As a controversialist, he eagerly and firmly maintains his own conclusions, and rapidly disposes of those of his opponents. For ourselves, we infinitely prefer such a writer to those mere compilers of other men's thoughts, whose weary volumes, surcharged with crude detail, tend rather to stem than to stimulate the development of subjective thinking.

A rapid summary of matured experience, such as is presented in the volume before us, though necessarily incomplete, insufficient for elementary teaching, and open to criticism, is far more serviceable to prepared and reflective minds, than more didactic and methodised treatises; for a book, after all, should be estimated by the amount of thought which it excites, as well as by the quantity of information which it conveys.

There is less than we imagine of what is, strictly speaking, *new*, in this art of ours; and mental sagacity has as much to do with its successful practice, as profundity and variety of acquired knowledge. Hence contact with an original thinker resuscitates our dormant energies, inspiring new interest in, and giving fresh expansion to the knowledge we possess.

The vindication of the author's claims to priority of theory as to the valvular origin of both of the cardiac sounds is the leading, though not the only interesting feature of the work. As no novel views are put forward, and as Dr. Billing's general opinions are already well known to the readers of his *Principles of Medicine*, we deem it unnecessary to offer any analytical exposition; and shall content ourselves with simply recommending the work to the student's attention. We have no doubt, after long practical experience, that the views propounded by Dr. Billing are, in the main, those which are most available for diagnostic purposes.

With the value of percussion he is evidently imperfectly familiar, and the difficulties of auscultation are, we think, understated by him; but notwithstanding these and other imperfections, characteristic of the one-sidedness of an independent mind, the book is a good one, and we can cordially advise its perusal.

SYPHILITIC DISEASES: THEIR PATHOLOGY, DIAGNOSIS, AND TREATMENT, including experimental researches on Inoculation as a Differential Agent in testing the Character of these Affections. By JOHN C. EGAN, M.D., M.R.I.A. 8vo., pp. 346. London: 1853.

OBSERVATIONS ON SYPHILIS, AND ON INOCULATION AS A MEANS OF DIAGNOSIS IN ULCERS AND DISCHARGES INVADING THE GENITAL ORGANS: comprising a brief outline of the Ancient and Modern Treatment of Syphilis, and pointing to new views, and to a new Method of Treating that Disease. By JOHN CROWCH CHRISTOPHERS, M.R.C.S. pp. 74. London: 1853.

TRAITÉ PRATIQUE DES MALADIES VÉNÉRIENNES, contenant un Chapitre sur la Syphilisation, et suivi d'un Formulaire Spécial. Par J. G. MAISONNEUVE, Docteur en Médecine, etc., et H. MONTANIER, Docteur en Médecine, etc. pp. 564. Paris.

In all the works on SYPHILIS which have recently appeared, the consideration of the results of *inoculation* has formed a considerable part, and afforded a subject of much interesting inquiry. One most important point, hitherto undetermined, has occupied the consideration of all the above mentioned writers, and demands our best attention. It is now generally acknowledged, that if inoculation be practised during the time that a chancre is in progress, or during the period that it remains stationary, the following succession of effects may be observed. During the first twenty-four hours, some redness appears at the spot where the inoculation has been made. From the second to the third day, there is some swelling, presenting the appearance of a pimple, surrounded by a red areola. From the fourth to the fifth day, the cuticle is raised by a more or less turbid fluid, affording often the appearance of a vesicle,

with a little dark spot in its centre. This spot is the result of the small effusion of blood at the time of the inoculation. About the fourth or fifth day, the secretion becomes increased in quantity, and more or less purulent in appearance. The centre of the pustule now becomes depressed, in this respect resembling the pustules of small-pox; at the same time, the surrounding redness may become fainter. From the fifth day, the subjacent tissue, which before had undergone no change beyond being slightly oedematous, becomes infiltrated by a plastic lymph, which affords to the touch the peculiarly hard and elastic feeling of cartilage. After the sixth day, the pus becomes thicker, the cuticle over it gives way, and scabs form on the surface of the part. When these scabs are detached, a chancre presents itself below, characterised by an indurated base, involving the whole thickness of the skin by a greyish white surface, composed of a lardaceous matter, or of a false membrane; and by its sharp and undermined edges, having generally a circular form. When inoculation, then, has been performed from an indurated chancre, its characteristic features are reproduced, and well marked and distinct evidence is thereby afforded of its nature. But the point to which we wish particularly at present to direct attention, is this:—*Can the matter from a simple chancre, unaccompanied by induration, when inoculated, give rise to an indurated sore, and may it become the source of constitutional symptoms?*

The present doctrine of the French school, represented by MM. RICORD, MAISONNEUVE, MONTANIER, etc., is, that if inoculation be performed from the matter of a simple undurated chancre of a fortnight's duration, and accompanied by a suppurating bubo, a simple chancre alone will be produced. This may assume different forms; it may become phagedenic, serpiginous, or gangrenous; but it will never become indurated, and will never give rise to secondary symptoms. The experiments from which these conclusions are drawn, were all made upon patients who had already had the venereal disease, and the results obtained are accounted for by the theory, that an indurated sore alone can produce constitutional syphilis, and that, under ordinary circumstances, a person can only once have an indurated chancre.

Our space will not allow us at present to inquire into the truth of these propositions; we must confine ourselves to the particular point to which we at first referred. What would happen if the matter from a simple chancre, of the nature above specified, were inoculated upon a healthy person? Would an indurated ulcer be the consequence, and would the patient be liable to secondary symptoms? Upon this point, authors certainly are not agreed; and the question, for very obvious reasons, cannot with propriety be tested by direct experiment. The French authors to whom we have referred, incline to the opinion, that an indurated chancre is always communicated by an indurated chancre; and that a simple chancre, accompanied by a suppurating bubo, is never capable of giving rise to an indurated sore, and consequently is not capable of producing constitutional syphilis.

On the other hand, Mr. EGAN, who is by no means alone in his opinion, observes:—"A numerous class of patients labouring under gonorrhœa afforded me ample scope for testing the accuracy of the results as set forward by eminent continental surgeons. In these cases I was unable, after repeated trials, to obtain any result by inoculation of the gonorrhœal matter, which I inserted by means of a lancet in the upper part of the thigh of the affected patient. But many cases presented themselves, in which the discharge was accompanied by *abrasion or superficial ulceration of the vaginal mucous membrane*, which was followed by a mild form of secondaries (generally a papular eruption over the body) although incapable of inoculation. Whether these abrasions, or simple excoriations of the mucous membrane, which existed in many cases coetaneously with the gonorrhœal discharge, were caused by the latter disease in its inflammatory or virulent stage, or by a specific virus, are questions by no means of easy solution; but certain it is, that not a few of them were succeeded by constitutional

symptoms where no other form of lesion could be discovered on the most minute and careful investigation."

Mr. CHRISTOPHERS takes a different view, and states his opinions much more broadly. He derives his conclusions, as he states, from the constant practice of inoculating every case that presented itself for some years. "I found," he says, "that no one case treated by inoculation, and proved thereby to be syphilitic, whether treated by mercury or otherwise, escaped secondary symptoms, under a more or less severe form; by which I imply (infer?) that secondary symptoms, in some shape, are the inevitable consequence of a genuine chancre, be the treatment what it may. The converse proposition holds good, that in no instance, the inoculation failing, have secondary symptoms supervened; therefore, let the treatment be mercurial, or let it be simple, if the case be one of genuine chancre, secondary symptoms, in some shape, will as surely follow, as that the sore will be reproduced by inoculating with the virus it secretes." (pp. 17-18).

We cannot refrain from expressing our conviction that these latter opinions have been too hastily generalized. The grounds upon which they have been formed, in fact, prove too much; for it is manifestly impossible for any one with any extensive opportunities of observation to trace every case to its termination. Even the most ardent supporters of the doctrines lately promulgated in France, admit that inoculation of the matter derived from a true chancre, like that derived from a small-pox pustule, will occasionally fail to produce any effect; and we believe this to be the first occasion upon which it has been asserted that a chancre is under all circumstances followed by some form of secondary symptoms.

We should have no difficulty, did our limits permit, in adducing cases, in which, on the one hand, inoculation has failed, and yet the patient has had secondary symptoms; and on the other, cases in which inoculation has been followed by a sore exactly resembling the one from which the diseased matter was taken, and yet where no secondary symptoms manifested themselves for months subsequently, if at all.

Before we can acknowledge any theory to be correct, with regard to so subtle a disease as syphilis, we must take care that the conclusions are derived from a sufficient number of well authenticated facts. The induction can, of course, only be correct in as far as every particular case agrees with the general law sought to be established; and the universality of the law must be established before we can allow that the reasoning is correct. A single well authenticated exception to any such general law destroys the truth of the induction.

NATURE AND TREATMENT OF SOME PAINFUL AFFECTIONS OF BONE. By LANGSTON PARKER, Esq. 8vo., pp. 16. London: 1853.

MR. LANGSTON PARKER, of Birmingham, has published a very interesting little memoir on the nature and treatment of some painful affections of bone. From cases which he has recorded, he deduces the fact that the shafts or extremities of the long bones may be opened with success for the purpose of relieving diseased conditions of their interior, besides those that are marked by the formation of matter. These conditions he believes to be marked by fixed and continued pain in a bone with or without enlargement of the shaft, of sufficient violence to threaten the destruction of the health and life of the patient, in cases where other remedies have failed to afford relief.

The cases which Mr. Parker has given are supposed by him to be instances of a congested or inflammatory condition of the medullary membrane of the interior of the long bones. In some cases, instances of such diseases may coexist with affections of the periosteum; in others they may be present alone.

Mr. Parker concludes that the shafts of long bones may be perforated or opened for diseased conditions of their in-

terior, such as he describes, with every probability of success, where all other modes of treatment have failed.

The subject of making artificial openings into the interior of diseased bones was brought under the notice of the profession, in some papers published in the *London Journal of Medicine*, by Mr. Henry Lee, previous to the appearance of Mr. Parker's interesting communication. Mr. Lee suggests the operation of trepanning as a remedy where long continued pain in bone depends, among others, upon the following causes:—"the formation of pus within the bone, the deposition of solid material arising from the poisons of mercury or syphilis, the collection of tubercular matter, or the presence of venereal cancellous structure." Both the above authors appear to have arrived at similar conclusions, although their investigations were evidently undertaken independently of each other; and both attribute to Sir B. Brodie the credit of having suggested the idea upon which their practice is founded. The propriety of making artificial openings into diseased bones where none previously existed, and where the existence of matter was not previously suspected, has not, however, we believe, been before acknowledged.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

CONNEXION OF CHOREA AND RHEUMATISM.

THE occurrence of chorea in connexion with or subsequently to rheumatism, has been noticed by several observers. At a meeting of the Medico-Chirurgical Society of Edinburgh, November 24th, 1852, Dr. J. W. BEEBIE related the case of a little girl, aged 10 years, who was attacked, on June 7th, with rheumatism. She passed through a very severe attack, and was convalescent on the seventeenth day. During her illness, she did not seem to suffer from disease of the heart or pericardium. On July 7th, Dr. Beebie ceased to visit her. On the 20th, he was called to her, and found her suffering from chorea; and, on examination of the heart, there was a distinct blowing murmur taking the place of the first sound, as heard towards the apex, accompanied by greatly increased action of the organ. Purges of jalap were given every three days, and afterwards Fowler's solution of arsenic, in doses of five minims twice daily after meals. This medicine was continued regularly from July 24th to September 20th. On September 23rd, the chorea had almost entirely disappeared; she walked well and steadily, though still complaining of occasional sinking at the knees; there were slight twitches of the muscles of the face. The murmur was distinctly heard over the whole cardiac region; most so towards the apex. On November 17th, the chorea had entirely ceased; there was still at times inordinate palpitation, and the murmur continued.

The author desired to direct attention to the association of disease of the heart, unattended on rheumatism, with the nervous disorder. He thinks that the evidence of some affection of the heart would be found in many cases of chorea. In Dr. Kirkes' analysis of thirty-six cases, three were of this nature. In some cases the cardiac affection would, no doubt, be found to be inorganic—functional derangement merely—attended by a murmur with the heart's first sound, heard most distinctly over the upper sternum, propagated in the cervical vessels, and in all probability associated with the so-called venous murmur in the neck. Further, the general appearance and symptoms of such patients pointed to the probable dependence of both nervous and cardiac affection on a disordered state of the blood.

But apart from these, in another class of cases, the evidence of organic disease of the heart, independent altogether of rheumatism, is quite as marked as its functional derangement is in the former. A boy, of seven years of age, was admitted into the Royal Infirmary, under Dr. Paterson, (now of Tiverton), suffering from a first but very severe attack of chorea. Immediately on his admission, a loud musical murmur was detected accompanying the first sound of the heart, heard most distinctly towards its apex. Neither in this boy's history, nor in that of any of the members of his immediate family, was there any account of rheumatism. Under treatment, the chorea speedily subsided; and after a residence of nearly a month, he left the

hospital, the cardiac murmur remaining as before. Scarcely six weeks afterwards, the little boy died suddenly.

The case now related established the correctness of the theory of Dr. Begbie, Sen., that the morbid condition of the blood, which gives rise to rheumatism, also gives rise to chorea. The child had inherited from two generations the rheumatic diathesis, and only became a sufferer from chorea on the declension of a rheumatic attack. Assuredly, no other theory which has been advanced so simply or correctly explains the now frequently observed facts of one member of a family being affected with chorea, another with rheumatism, and perhaps a third being the subject of both affections. But there still exist several very interesting circumstances, which require more attention and investigation, before the association of these two diseases shall become thoroughly understood.

Dr. SIMPSON mentioned some cases in which he had seen the connexion of rheumatism with chorea. In one case that he attended some time ago along with Dr. W. H. Douglas, the patient, a young lady of seven or eight years of age, after suffering from severe rheumatism in the lower extremities, presented symptoms of chorea, and ultimately, in the course of the disease, was attacked with subacute pericarditis, which proved fatal. The effusion of coagulable lymph on the pericardium, as ascertained by dissection, was extremely great. He saw, some years ago, with Dr. Robertson, another case in an adult, in whom, first, there occurred rheumatic fever, followed by pericarditis; and, secondly, when this pericarditis was at its height, symptoms of chorea supervened. The patient recovered, but with a heart much diseased by the attack. He had seen in one family a set of cases similar to those described a few years ago by Dr. Begbie. Two children, a sister and brother, were attacked with rheumatism. In the boy, the rheumatism was followed by an affection of the heart, which proved permanent, and was probably inflammatory in its origin. In the sister, the rheumatic attack, on the other hand, was followed by severe and prolonged chorea, complicated with a kind of hemiplegia. She recovered at last, under the use of arsenic. The investigations which have been lately published by some French pathologists seem to show that the connexion between chorea and rheumatism is even more frequent than had been previously supposed, particularly among young children. In the *Parisian Hôpital des Enfants*, attention having been particularly directed to this subject, more cases had been found of chorea and rheumatism combined among the young patients than of simple uncomplicated rheumatism: at least, such is the avowal of M. Sée. This pathologist further stated, that in the *post mortem* examination of individuals dying of chorea, between 35 and 40 per cent. of the bodies were found to present inflammatory effusions upon the surfaces of internal serous membranes; and pericarditis was one of the most common of these complications. Dr. S. believed that the old explanation attempted to be given of the connexion of chorea and rheumatism, as to its being a nervous or sympathetic connexion, etc., could not now be sustained; and that the pathological idea of the relation maintained by Dr. Begbie was the correct one, viz., that these two apparently different diseases depended upon some identical or analogous blood-poison. Dr. S. entertained little doubt, that when pathological chemists discovered what the blood-poison in rheumatism really was, that the same blood-poison, or some modification of it, would be found to be also the cause of chorea, however much the two diseases differ symptomologically. The morbid state of the blood existing in rheumatism and chorea predisposed, as late dissections have shown, to produce inflammation of internal serous membranes. The morbid state of the blood in albuminuria had, in a noted degree, the same tendency, as specially shown by Dr. Taylor and others. These two morbid poisons were analogous in another respect. While the poisoned state of the blood accompanying or produced by albuminuria had a tendency in some individuals to produce local serous inflammations, it tended in others, and particularly in pregnant females, to affect the nervous system in the form of convulsions. So the blood-poison in rheumatism, whatever its nature might be, had a tendency, in the same way, to produce internal serous inflammations in some individuals; and in others, particularly in the young, and in the female sex, to affect the nervous system in the form of chorea. Both thus had a tendency to produce, on the one hand, internal serous inflammatory lesions, and on the other, peculiar affections of the nervous system. Perhaps a closer investigation would prove them also to be analogous in other respects.

ON VITILIGOIDEA.

Dr. W. H. RANKING, of Norwich, thus describes and comments upon a case of vitiligoidea in the *Lancet* of 10th February.

The instances of this curious malady hitherto put in record do not amount to more than five.

CASE. Mary B—, a married woman, aged twenty-nine, consulted me, in June 1850, for obstinate and severe jaundice. Inquiry into her history elicited the facts that her health had been good until three years previously, when, after an attack of dyspepsia, jaundice supervened, and had continued till the time of her visit to me, uninfluenced by treatment, including several salivations. At this time she was universally and deeply jaundiced; but the appearance which immediately and more strongly attracted my attention was a peculiar deposit on the skin surrounding the eyes, and which, on further investigation, I found to be abundantly distributed over other portions of the body. She informed me that, about twelvemonths ago, spots of this peculiar deposit first appeared on the shoulders, and had since shown themselves on the face, arms, hands, and lumbar regions. In the face it had assumed a symmetrical disposition, extending along each eyelid, and down the side of the nostrils. On the shoulder the spots were circular, and very distinctly elevated. Along the inside of the elbows, and on the hands, the deposit followed the flexures of the joints, being flat and linear on the palmar aspect, and more tubercular and rounded on the dorsal. The colour of this deposit was of a whitish yellow, resembling more nearly than anything else the atheromatous patches so commonly found in the aorta. On the face, and palms of the hands, it was but little elevated; and, as in atheroma, appeared to be deposited immediately under the epithelium. On the shoulder, and in the dorsal region, the spots were circular and prominent, bearing no inconsiderable resemblance to split peas.

At the time of my seeing this case, the peculiar affection was still on the increase, fresh spots showing themselves almost daily. They were tender to the touch, and were the seat of a burning sensation, which prevented the patient using her hands without acute suffering.

The history of the jaundice pointed to the conclusion that it depended upon permanent occlusion of the common duct. The woman died soon after my seeing her, under the care of another practitioner, (as far as I could learn,) from severe and rapid peritonitis.

The only references to this singular cutaneous disease which I have been able to meet with, are contained in a paper by Dr. Gull, published in *Guy's Hospital Reports*; for although Willan alludes to a rare disease under the term *vitiligo*, which has some points of resemblance, the full comparison of the two is unfavourable to the notion of their identity. The term used by Willan has, however, led Dr. Gull to give to the disease in question the name *vitiligoidea*. The cases narrated by him are four in number.

The first is that of a married woman, aged 42, who had been deeply jaundiced for two years. At the end of fourteen months, this peculiar change in the integument began to show itself on the eyelids, assuming a perfectly symmetrical form, as well as in the palms of the hands, where, as in my case, it followed accurately the flexures of the joints. The disease remained stationary till her death.

A second patient was admitted into Guy's Hospital, labouring under diabetes; but in this instance the eruption was so far different in its aspect, that I cannot think Dr. Gull justified in associating it with the former case.

The third instance is that of a married woman, like the first, the subject of jaundice. The skin disease commenced at the end of fourteen months, appearing first on the hands, and subsequently affecting the eyelids. This case is now, I believe, under treatment, but the disease shows a tendency to increase rather than diminish.

The fourth case described by Dr. Gull is, in every respect, similar, both as to the prior existence of jaundice, and the distribution of the cutaneous deposit.

It is impossible to overlook the important fact of some connexion between the cutaneous deposit and jaundice of aggravated degree and prolonged duration. In every case reported, obstinate and severe jaundice had existed for several months prior to the appearance of the skin malady. Can it be that, like the cretaceous deposits of gout, this was an attempt at elimination of noxious matter necessarily contained in blood, in which was suspended the elements of bile? I regret much that I had no opportunity of instituting a microscopic examination of the deposit; but its *primæ facie* resemblance to atheroma would warrant the idea that, like the latter exudation, the peculiar deposit

in question contained cholesterine, a principle which is well known to enter largely into the composition of the biliary secretion.

If, as I imagine, the affection is but a symptom of prolonged retention of bile, or its elements in the blood, nothing in the way of amendment can be anticipated unless the original malady be removed, when possibly the absorbents might spontaneously remove the deposit. In the cases hitherto recorded, no decided amendment followed any of the means adopted.

EXAMINATION OF THE FÆCES IN DISEASE.

Dr. JONATHAN OSBORNE, of Dublin, has published a valuable paper on this subject in the *Dublin Quarterly Journal of Medical Science* for February 1853. We quote the article nearly entire.

The most complete chemical examination of them is that of Berzelius, which has not yet been superseded by any other:

Water	73.3
Bile	0.9
Albumen	0.9
Extract	2.7
Salts	1.2
Insoluble Residue of Food	7.0
Mucus, Bile, Resin, Fat, etc.,	14.0
			100.0

A striking fact to be observed in this is the large proportion of water, approximating to that of the urine, which according to the same authority, amounts to 93 per cent. of that secretion.

The quantity of the entire discharge is influenced by diet, but still more by torpidity of secretion from the mucous surface, the epithelial scales at their formation containing water, which is afterwards absorbed when retained. Thus in old persons of sedentary habits, also in several animals, the fæces are hard and dry like those of the dog, and consist chiefly of bony or other indigestible materials, resembling coprolites, or fossil fæces.

The time occupied between taking in articles of diet and their arrival at the rectum, appears to be about fourteen hours. This is ascertained by observations with pips of grapes or raisins, which pass down unaltered.

The number of discharges consistent with healthy digestion is much under the influence of habit, averaging from three times daily, or oftener, to once a week. As a general observation, females have the greatest tendency to retain.

In proceeding to the examination of the fæces we have three characters to guide us, which serve as fixed points from which all our observations commence. These are, 1st, the colour; 2nd, the odour; 3rd, the consistence. The colour is acquired in the duodenum, and derived from the bile; the odour, from the glands at the cæcum; and the figure and consistence, from the colon and the rectum.

1st. COLOUR. When the common duct is obstructed, as in certain cases of jaundice, the fæces are devoid of colour, having only a grey aspect, resembling that of putty. And here it is necessary to make a careful distinction between the colour of the faecal masses, as originally formed in the duodenum, and that of the mucous fluid discharged from the surface of the bowels. In many cases of jaundice we see fæces consisting of those white masses resembling putty, but surrounded by yellow or green liquids. In these the secretions from the surface of the intestines are, in common with the blood and urine, more or less charged with bile, but the faecal masses themselves remain distinct, and continue as they were at first in the duodenum, free from bile, although in health they are the special vehicle for its removal from the body; and this explains a case described by Andral,* in which he found it difficult to reconcile the fact that, along with jaundice and colourless motions, the patient yet had copious bilious vomitings. In such cases the secretions of the stomach, in common with all the other fluids of the body, may be jaundiced, and the fæces may be even partially stained by them, but their interior resists their further entrance, and they continue distinct up to the time of their expulsion. This observation is the more necessary, as such discharges are often described as bilious.

In the more transient cases of jaundice sufficient time may not elapse to affect the blood so as to reach the mucus of the intestines, which usually does not become stained until after the discolouration of the conjunctiva, and the whole discharge thus continues altogether colourless. There is another form of jaundice worthy of particular notice. In this the fæces are well

and thoroughly coloured, although the skin, the blood,* and the urine, continue highly jaundiced. Here as the bile passes freely into the duodenum, the hepatic duct must be free, and if so, then the cause of the jaundice must exist in the *pori biliarii*, or in the substance of the liver itself. And this conclusion is almost uniformly verified by the further history of such cases, revealing, when long protracted, either congestion or cirrhosis of the liver, or schirrous tumours within its substance.

In health the shades of colour vary from a bright yellow, which is that of the freshest secreted bile, to a dark olive-green, which is the colour it acquires when retained in the gall-bladder. The passage of this black bile succeeding to feelings of sadness and depression, has no doubt been the origin of the word *melancholy*. Sometimes these discharges take place during the enjoyment of ordinary health, but the individual always experiences a change in his spirits for the better,—cheerfulness and contentment succeeding at once to dejection and moroseness; and what is worthy of remark is, that this improvement in his spirits comes on, not always after the discharge, but sometimes a few hours previously: showing that it is not to the expulsion of it from the bowels, but to the discharge of it from the hepatic ducts, that this happy effect is to be ascribed.

During their stoppage in the colon, the colour of the fæces changes from yellow to brown, becoming deeper and approaching more and more to that of sepia when long retained; and even the white masses belonging to jaundice, when retained there, undergo the same change, but certainly in a much less degree. From this we are enabled to judge of the relative age of accumulations in the colon, and, after the manner of geologists, to pronounce our decisions between the old formations and the later deposits.

With respect to blood in the fæces, it assumes three distinct forms: first, when effused into the stomach, and the globules, under the chemical agencies of that organ, acquire a black colour, constituting the melenous discharges passed both by vomiting and purging; second, when effused into the smaller intestines, and in smaller quantity, and mixed up with the fæces so as to impart a reddish colour, as from an addition of ochre or brick-dust, which, to the eye prepared to look for it, is very apparent, although commonly overlooked, and evidently different from any colour which can be imparted by bile. This colour is of frequent occurrence in those cases of enteritic inflammation, in which ulcerations of the small intestines are usually found. The third form is when blood is effused so low down in the tube that it is not mixed with the fæces, either solid or fluid. In such cases it is almost always dark, and varies in quantity from those large discharges which have been often attended with fatal consequences, to those cases in which small portions of sanious matter are to be seen scattered through fluid fæces, but not mixed with them, as occurs in ulcerations of the colon; or lastly, to that mere sprinkling of a few tears of blood shed over the faecal mass, from hæmorrhoidal tumours near the rectum.

The green discharges following the use of calomel in children have been too remarkable to be entirely overlooked. By Dr. Graves, and other eminent observers, they have been considered as products of irritation of the mucous surface, and not necessarily to consist of bile, as had hitherto been held; and in 1845 Dr. Golding Bird,† from his experiments, regarded the presence of green stools to be indicative, not of a copious secretion of bile, but of a congested state of the portal system in which blood is exuded very slowly, and in small quantities, so as to allow of the colour to be affected by the gases and secretions present in the intestines,—a state of things which he considered to differ from melaena only in this, that in the latter the effusion of blood is so copious and sudden as not to give time for this change to take place.

It must be admitted that sulphuretted hydrogen is capable of changing the colouring matter of the blood to an olive-green; and that sanguineous exudations may in this way be the source of green evacuations; but that they are not exclusively the cause of them is to be inferred, not only from the dark-green colour which the bile receives when retained in the gall-bladder, but from the experiments of Dr. Michéa,‡ from which, in the cases submitted to his observation, this green discharge was

* In order to obtain the earliest indication of jaundice in the blood, the following method will be found peculiarly convenient and satisfactory. Obtain a few drops of serum from the patient, which, when bleeding is inexpedient, may always be had from a blister, however small. Diffuse it to the size of half a crown on a piece of white porcelain; then drop into the centre one drop of strong nitric acid: a pool is immediately formed, surrounded by a ring of white coagulated albumen, which in a few seconds assumes a beautiful bluish-green colour if bile is present.

† Medical Gazette.

‡ Lancet, January 1849.

* Clinique Médicale, by Spillan, part v, p. 987.

proved to be connected with excess of bile. As those green motions, then, may be produced from either of these causes, and in some from the coexistence of both, they offer an interesting subject of inquiry to those engaged in the treatment of diseases of children, in order to obtain tests to identify and distinguish them.

In Asiatic cholera, as is well known, the fæces cease to have either colour, odour, or consistence, being the *conjee* fluid containing albumen diffused in water, the proportion of which is generally more or less according to the quantity of fluid drank, while the epithelial scales disappear almost entirely, but subsequently re-appear according as recovery approaches.

Although most substances taken into the stomach are decolorized in the process of digestion, yet some are to be noted as remarkable exceptions. These are spinach, logwood, coffee, and porter, which, in this respect, resist the action of the stomach, and impart their own colour to the fæces. The black colour produced by the salts of iron may generally be explained by their action on astringent matters in the bowels; but this fails when the same effect is produced in persons whose diet consists only of potatoes, milk, and animal food.

2. The odour of fæces appears to have been especially intended to deter animals from feeding on their own excrements, — a practice into which some of the more ravenous species would be likely to fall. This odour is not produced by putrefaction, for the fæces have no alkaline re-action, and are rather acid; and to suppose putrid matter to be retained more or less within the system would be contrary to all analogy, which shows such to exercise a poisonous and often fatal influence. That this odour is derived from the secretions of the glands at the cæcum is proved by the fact, that the fæces do not acquire it until they have arrived at this part; that here it is at its greatest intensity; and that it diminishes in the fæces according as they proceed on their passage to the rectum.

This secretion at the cæcum is altered by various circumstances. Sometimes it acquires a pungency almost intolerable, as is observed even in cases of slight diarrhoea, when, after the more solid contents of the colon and rectum have passed, they are succeeded by dark-coloured fluid motions, consisting of fresh arrivals from the cæcum, of such overwhelming potency that even the most experienced and apathetic physicians are compelled to a speedy flight, and content themselves with describing them as "dark, bilious, and highly offensive." The most decided proof of the vital origin of this odour, and of its independence of the food taken, is afforded at the commencement of dentition in infants. The fæces, which, previously to that time, are of a merely sour and sickly odour, suddenly acquire that most abominable and peculiar odour belonging to ulceration of a bony surface, or such as comes from the ear in destructive suppuration of the labyrinth; and from this alone the practitioner may generally predict a fit of teething. On the other hand, in some of the most severe and protracted cases of enteric fever, when once the bowels have been cleared of their old contents, there is no longer any odour in the discharges; and this continues all through the fever until a favourable change takes place, when the natural odour is resumed, according as the natural functions of the parts are restored.

3. The SHAPE and SIZE of the fæces are derived from the large intestines. In the horse, the rabbit, the goat, the sheep, and the pig, they are moulded so as to present us with casts of the cells of the colon. In the human subject their first shape is also derived from the cells of the colon, and they are sometimes indurated so as to resist further compression, forming in such cases fragments of various sizes, known as scybala; but, when retaining their softness, in general they are altered in their passage through the rectum, the action of the sphincters causing both elongation and curvation. Enlargement of the prostate forms a groove in the anterior, and frequently compresses them as if they had passed through a flattening mill; while in the case of internal hæmorrhoidal tumours, they show by their grooves or notches, and streaks of blood or sanies corresponding therewith, both the size and situation, and often may throw important light on the nature, of such tumours.

When the mucous membrane of the rectum is inflamed, as in dysentery, then in the height of the disease the discharges are altogether mucous, sanious or purulent, and an abatement is usually taking place when faecal matters are allowed to pass. But in inflammations of the colon, as long as the rectum remains unaffected, the discharges are feculent but frequent and largely diluted with mucus, so that from an inspection of them alone, the distinction may be made between dysentery and diarrhoea.

In irritation or inflammation of large tracts of the intestines,

the discharges exhibit alterations corresponding with the amount of irritation and in proportion as they are presented either by the whole, or only by a part of the discharge. We are also informed of the extent of surface affected. These alterations may be described under four general characteristics, as follows.

The *first* and slightest degree of irritation is indicated by discharges differing from those of health only in greater fluidity, and absence of shape or consistence. Such occurs, for example, when a healthy individual takes a saline purgative. All our ordinary purgatives act by irritation, and after the solid contents of the large intestines have been evacuated, then follow the loose motions forwarded from the cæcum and small intestines, mixed and accompanied by large quantities of mucus.

The *second* degree of irritation is indicated by discharges of a waxy consistence, of a lesser specific gravity, floating on the urine, and frequently intermixed with air bubbles. Such are rarely seen from the operation of a gentle purgative in a healthy individual, and are almost always preceded or accompanied by symptoms, more or less marked, of irritation in the intestines, such as pain, heat, or tormina.

The *third* degree of irritation is indicated by discharges of a powder without coherence, and either diffused or lying at the bottom of the urine. The colour of it is generally pale, but varies in this respect according to the state of the biliary secretion, or the degree in which blood may have been effused. It appears to consist of minute exudations of fibrine or coagulated albumen, and constitutes most of the discharges seen in the milder cases of enteritis, and is of most common occurrence in all idiopathic fevers accompanied by white dry tongue. In whatever cases these discharges occur, they are a certain evidence not only of the existence of mucous irritation in the bowels, but of a degree of irritation requiring, even under the most favourable circumstances, some days for its removal.

The *fourth* and highest degree of irritation is denoted by discharges consisting of white shreds or tubes of fibrinous exudation. These are the products of the same kind of inflammation seen in croup, or the most violent forms of cynanche, and consist of lymph thrown out in the same way. With respect to purulent discharges from ulcerations in the small intestines, although such must occur, yet I have not been able to distinguish them, nor, according to my observations, can pus be recognised at all, unless it is unmixed, as when it comes from the lowest portions of the intestines.

As connected with the appearances belonging to this fourth degree of irritation, I wish to remind the reader that castor oil occasionally, but by no means uniformly, or even frequently, produces discharges liable to be mistaken for the above. These are white ovoid masses, in colour and consistence resembling boiled macaroni, and about the size of grapes. They have been chemically examined by Dr. Golding Bird,* and he considers them to be a hard soap, formed by the union of the oil with some alkaline matter in the bowels.

Heterogenous motions are of frequent occurrence. In these we see one part of the motion fluid, another solid, or one part pulverulent, another waxy or in shreds, or all the four together. Such different appearances in the one motion are the result of different degrees of irritation in distinct portions of the tube; and it is our duty, by the assistance of these indications, compared with the symptoms of the case, to ascertain the seat of the irritation. For this purpose, we have several well established facts. Thus, in hæmorrhoidal tumours or fissures, pain at or immediately after passing a motion; in inflammation of the rectum, tenesmus; in inflammation of the colon, diarrhoea; in inflammation at the cæcum, tendency to constipation, local pain at that part, and more or less peritoneal inflammation supervening; and in inflammation of the small intestines, sense of fullness around the umbilicus, with sudden bursts of diarrhoea, alternating with constipation. Taking these facts in connexion with the discharges, they will be found to serve as mutual interpreters of each other.

These cases of fecal vomiting on record appear to me to belong merely to regurgitations of matters coloured with bile from the portion of the duodenum below the biliary duct. It has never befallen me to witness any instance in which fæces having the triple character, namely, colour, odour, and consistence, have been vomited; and I have met with only one report of a case in which such an event undoubtedly took place. It is in Dr. Abercrombie's work. In it there was an ulcer of the stomach, corresponding to one of the arch of the colon; and the fully formed fæces from the colon passed directly from it into

* Medical Gazette, November 1834.

the stomach, and were rejected by vomiting. I am aware that many cases of faecal vomiting have been mentioned, but it was recognised as such merely from colour, and in disregard of the other peculiar characters of faeces.

MICROSCOPICAL DISCOVERY.

STRUCTURE OF THE SENSITIVE PAPILLÆ OF THE SKIN.

Several German physiologists are vigorously prosecuting researches on this subject. Rubner's *Medizinische Zeitung* for 1852, part VIII, contains the results of the investigations of NUHN and GERLACH; the latter of whom is so enthusiastic, that he is actually screwing up his courage to cut a bit out of the point of his own finger, that he may have the *cutis vera* in prime condition to examine: "ein allerdings heroischer Entschluss, zu dem ich mich bis jetzt noch nicht verstehen konnte".(!) No wonder: the greater marvel being that he did not ask some surgical friend to let him know when he had the amputation of a finger to perform.

The observations in question confirm in the main those of WAGNER (*ASSOCIATION JOURNAL*, No. I, p. 20), except as to the mode of termination of the nervous filaments in the papillæ, which both Nuhn and Gerlach assure us is by loops. The drawings given by the former especially (one of which we have copied in Fig. 1), are so numerous and distinct, that we can hardly believe him in error on this point, or to have mistaken capillary vessels for nerves. It is, however, plainly a very difficult research; for which no further proof is needed than a comparative inspection of the figures given by Nuhn and Gerlach respectively; the latter describing the nervous tubule as forming a spiral coil round the "corpusculum tactus", and ending by a loop near its apex. (Fig. 2.)

Fig. 1. Corpuscle-bearing papilla, after Nuhn. 300 diam.
Fig. 2. Corpuscle-bearing papilla, with capillary, after Gerlach.

The most interesting fact elicited, however, is the close connexion of the *corpuscula tactus* with the (discriminative) sense of touch. The papillæ of the skin may be divided into two sets, those containing the *corpuscula* and those destitute of them; and even in the skin of the finger tips, where the former are most numerous, they are outnumbered by the latter in the proportion of about five to one. The skin of some of the most sensitive parts of the body—the glans penis, for example—is utterly destitute of corpuscle-bearing papillæ, while it is very rich in ordinary sensitive papillæ and in nerves—a fact which appears to prove that these corpuscles are connected, not with general sensibility, but with the power of *discriminative touch*, which is not exercised by parts such as the glans penis, but which the fingers, the lips, and the point of the tongue, so eminently possess: and, accordingly, it is in these regions that the "tastkörperchen" are found.

On the back of the hand, for example, they are very rare; and in general it appears that their frequency agrees with the capacity of the skin for feeling, as measured in the old experiment with compasses. It would be very interesting to examine the skin of blind men, and find whether the preternatural acuteness of their touch is owing to an unusually plentiful crop of "tastkörperhaltige Papillen".

In our last report, we ventured to think it very improbable that Wagner should be right in supposing the papillæ in ques-

tion to be destitute of vessels; and the researches which we now notice prove that we were right (Fig. 2); and the extreme (ordinary) sensibility of parts where they are not found, makes it, *a priori*, improbable that the papillæ which contain no corpuscles are destitute of nerves. This has also been confirmed by observation—first, of abundant nervous filaments in the skin of such regions subjacent to the papillæ; and, secondly, of nervous tubules actually entering the papillæ, and forming loops within them. (Fig. 3.)

Fig. 3. Papilla without corpuscle, but with nervous tubule and capillary, after Gerlach.

The question is agitated, whether the *corpuscula tactus* are organs, or merely serve—as the nails, for example, do—to place the nervous filaments in a favourable position for receiving impressions, by giving them the requisite support and steadiness. But, after all, this is a foolish question. The sense of touch does not require a labyrinth or an eyeball as its organ; but surely the finger point is as much an organ as either of these: the phalanx is its turbinated bone, the nail is its concha, well suited for the necessities of the sense, and the *corpusculum tactus* is its vitreous humour and lens, giving to the nervous tubule the support necessary to enable it to receive aright the impressions of touch.

THE MINUTE STRUCTURE OF THE SPLEEN.

Since the recent publication of the fourth edition of Dr. Carpenter's *Human Physiology*, which embodies the latest researches on the structure and functions of the Ductless Glands, Mr. WHARTON JONES has reviewed (*British and Foreign Medico-Chirurgical Review* for January 1853, p. 32) some of the opinions held by KÖLLIKER on this subject, and has introduced an account of his own examination of the structure of the spleen, of which the following is an abstract.

The parenchyma of the spleen consists of two different substances; a red pulpy looking matter pervaded by a capillary network, and the whitish Malpighian corpuscles imbedded in it.

Examined microscopically, the pulp is found to consist of nucleated corpuscles and short nucleated fibres, held together by a finely granular intercellular substance, in the latter of which its red colour resides. The Malpighian corpuscles are of a roundish shape, about one-fiftieth of an inch in diameter, and, examined with a low magnifying power, present the appearance of thick walled glandular vesicles, with contents. The walls are not defined and homogeneous, but are, on examination with a high power, found to be composed of nucleated fibres and corpuscles, similar to those of the pulp; between which, indeed, and the exterior surface of the corpuscles, there is no very distinct line of demarcation, other than is produced by the condensation of the wall of the Malpighian corpuscle, and the absence from it of colouring matter.

The contents of the Malpighian bodies are nucleated granular corpuscles and nucleated cells, similar to those of the red substance, cohering together in a mass by means of a diffuent intercellular substance; and interspersed among them are a few somewhat larger nucleated cells.

The author next proceeds to compare the blood of the splenic artery with that of the splenic vein. The former does not differ from that of other arteries; but the latter is peculiar, containing, besides the ordinary blood-corpuscles, a large number of nucleated corpuscles and fibres identical with those above described as composing the red pulp of the spleen, together with free nuclei similar to those of the nucleated corpuscles. These elements were traced as far as the vena porta, but in the vena hepatica they had almost entirely disappeared.

"The anatomical inference which might be drawn from the

facts now related is, that some of the venous radicles of the spleen have a connexion with the red pulp of the organ, similar to that which exists between the radicles of the hepatic duct and the parenchyma of the liver: whilst the *physiological inference* is, that the materials thus derived by the blood from the spleen may concur in fitting it for the secretion of bile."

THE INTERSTITIAL GROWTH OF BONE.

In the *Philosophical Magazine* for 1852, p. 467, there is contained the abstract of a paper presented to the Royal Society by Messrs. TOMES and DE MORGAN, in which they give an account of their researches on the nutrition of bone, interesting not only for its own sake, but as throwing light on the general subject of the interstitial growth of tissues.

The authors oppose the opinion of Dr. Sharpey, that the ultimate structure of bone is fibrous; describing it as being composed of fine granules imbedded in a structureless hyaline matrix, an arrangement of parts which is most distinctly seen in young bone.

Our readers will remember that osseous tissue consists of an aggregation of "Haversian systems", each composed of a central "Haversian canal" (conveying the vessels), surrounded by concentric laminae of bone. When, in consequence of their curvature, these Haversian systems separate from one another, the intervening space is filled up by "interstitial laminae" of bone, having the appearance of broken fragments of former systems. And this in truth they are; for our authors hold that they have proved the Haversian systems to be of various ages, and the older ones to be gradually absorbed, leaving spaces which are filled up by newly formed systems, in the intervals between which the relics of the old may still be seen. In some cases these last are thoroughly removed, so that there are left small triangular vacancies, called by the authors, "Haversian spaces".

The process of this interstitial reproduction is very interesting: as the absorption of the old tissue goes on, it is replaced by granular cells (i. e., cells having the appearances of granules?) imbedded in a hyaline matrix, the whole of which structure gradually ossifies, the cells becoming the granules of bone, and the matrix form the structureless tissue first described.

The cells in question having been from their first appearance arranged in parallel concentric lines, the ossified tissue has of necessity the laminated arrangement observed in the Haversian systems; while certain larger cells which exist among them become converted into the lacunae of bone by the ossification of the cell-wall.

In young bone, as we have said, the granular structure may be most distinctly seen, and the lacunae are large, numerous, and empty; in older bone, the lacunae are gradually filled up with osseous matter, and even the Haversian canals with which their canaliculi communicate may become obliterated by a similar deposit, which, of course, must in the same measure exclude vessels from the bone.

The interesting point in these observations is the demonstration of interstitial absorption which they make. In this hard bony tissue, in which we might have supposed it impossible to trace these minute changes, we find them, on the contrary, marked out and defined as they could not be in the more rapidly changing, but soft and yielding matter of muscle or of nerve.

THE PATHOLOGY OF LEUCORRHOEA.

The practical application of the microscope to medicine could not be better illustrated than in a paper bearing the above title, published by Dr. TYLER SMITH, in the 35th volume of the *Medico-Chirurgical Transactions*. An epitome of this very interesting communication we proceed to lay before our readers.

The parts concerned in leucorrhœa are the mucous membrane of the vagina, that of the os uteri and of the vaginal surface of the cervix, and that which lines the last named canal; these several portions of mucous membrane present important peculiarities of structure.

The *Vaginal Mucous Membrane* is covered with scaly or pavement epithelium, and its secretion is acid; in both respects closely resembling skin, into which, in old cases of prolapsus, it seems to be almost converted.

The *Mucous Membrane covering the external part of the Cervix, and the Os Uteri* is thickly clothed with villi, which contain looped capillaries, and are covered by a thick layer of scaly epithelium. This obscures the villi, and as they appear indistinctly through it, they may be easily mistaken for follicles in the membrane. The relationship to the skin is as strong here as in the vagina.

The *Mucous Membrane of the Cervical Canal of the uterus* differs most materially from either of the above; for a very short distance within the os uteri it appears smooth to the naked eye, but above this it is thrown into complex folds or rugæ, forming the structure described by anatomists as the *arbor vite uterina*. Both these divisions are covered with villi, vascular like those of the outer cervix, but three or four times as large; and the villi are clothed with cylinder epithelium, like that of the small intestine. This epithelium is ciliated over the rugous surface, but destitute of cilia where it covers the narrow smooth slip of mucous membrane close to the os. Donnè long ago pointed out, that mucous surfaces covered by scaly epithelium have an acid secretion, while that of membranes clothed with columnar epithelium is alkaline; and this rule holds good here: the alkaline reaction of the secretion from the cervical canal of the uterus being a most important point in its pathology.

A most complicated arrangement of the mucous membrane provides surface for this secretion. The naked eye discerns on the inner surface of the neck of the uterus a number of transverse rugæ, arranged in four columns, ten or fifteen rugæ in each, while secondary rugæ run crosswise between the primary ones; and the lens enables us to detect a still more complicated arrangement of septa, or mucous folds, uniting the secondary rugæ.

A still higher magnifying power reveals the object of this structure, showing it to be for the purpose of giving a greater surface to the membrane, the whole of which is studded over with myriads of secreting follicles. Of these, Dr. Smith calculates that the neck of the womb contains no fewer than ten thousand. Our readers will now be prepared for the statement, that this cervical mucous membrane performs the function of a gland, and that it is the principal source of the flux in leucorrhœa.

And now for the application of these anatomical facts, to explain the phenomena of the disease just named. On examination with the speculum, the discharge which smears the vagina and the os uteri appears white and creamy, that which is escaping from the os, transparent and viscid; and yet microscopical examination does not reveal differences corresponding to such diverse characters. Dr. Smith finds the explanation of this fact in the different chemical reaction of the secretions from without and from within the os uteri. The alkaline secretion of the cervical canal remains viscid and clear, till it mixes with the acid contained in the vaginal mucus, when its albumen is coagulated, and it assumes the aspect well known as that of the usual leucorrhœal discharge; and this conversion can be imitated out of the body by mixing the clear tenacious mucus drawn from the cervical canal with weak acetic acid. (Our readers are no doubt aware, that a change exactly the reverse of this is produced by mixing pus with liquor ammoniæ.)

We now understand why "vaginal leucorrhœa" should be considered to be so common, and "uterine leucorrhœa" so rare; and why this opinion may be exactly opposite to the fact.

If Dr. Smith's opinion be correct, the mucous lining of the cervix is that which, being organized for secretion, pours forth the flux in question most profusely; but on its entrance into the vagina, its character is changed, and the practitioner traces no identity between the viscid transparent mucus which he rightly supposes to be the characteristic secretion of the cervix, and the creamy "leucorrhœal discharge" which appears at the ostium vaginæ.

The quantity of this discharge undergoes variations, which can be accounted for only on the supposition of its being derived from a fully organized glandular surface; the secretion, which in health ought to form little more than a plug of mucus, is sometimes so suddenly increased on exertion or on mental emotion, as to remind one of the manner in which a flow of tears is produced.

We have already said, that the microscopical differences between the vaginal and cervical secretions are not commensurate with the great diversity of their external character; but some difference may be traced,—the former abounds more in scaly epithelium, the latter in roundish "mucous" (?) corpuscles.

The treatment of leucorrhœa must, of course, vary with its cervical or vaginal nature. When the discharge is from the external passage, astringent injections into the vagina will be most useful; when from the interior of the neck of the womb, stimulating and astringent substances, such as iodine, nitrate of silver, and tannin, may be applied in solution, by means of a camel-hair pencil, directly to the part in fault. On the treatment, however, Dr. Smith does not enlarge in his present communication.

The superficial ulceration of the os uteri he attributes chiefly to the irritation of the mucous surface by the alkaline discharge from a morbidly secreting cervix; and this may go on till it has destroyed the villi of the membrane in irregular patches around the orifice of the womb. "I have very rarely found the os uteri abraded without the existence of disease of the glandular portion of the cervix, unless in cases of eruptive disease. I have also found in treatment, that the best way to restore the os uteri is by restraining the cervical secretion; but that the morbid state of the os uteri may be remedied again and again, with tolerable certainty of the recurrence of the disorder, unless the cervical secretion be brought back to the healthy condition."

If ulceration have taken place, the discharge will, of course, contain pus, and even blood.

Lastly, Dr. Smith warns us against mistaking for an ulcer the partial eversion of the cervix uteri, which brings into view the lower rugæ. These present an appearance which one might easily mistake for a deep erosion.

ANATOMY AND PHYSIOLOGY.

ON THE MUSCLES WHICH OPEN THE EUSTACHIAN TUBE.

The following is an abstract of a paper read before the Royal Society on February 17th, 1853, by Mr. TOYNBEE:—

The author commenced by alluding to the opinion generally held by anatomists, viz., that the guttural orifice of the Eustachian tube is always open, and that the air in the tympanum is constantly continuous with that in the cavity of the fauces. An examination of the guttural orifice of the tube in man and other animals has led the author to conclude that, except during muscular action, this orifice is always closed, and that the tympanum forms a cavity distinct and isolated from the outer air. The muscles which open the Eustachian tube in man, are the tensor and levator palati; and it is by their action during the process of deglutition, that the tubes are ordinarily opened. That the act of swallowing is the means whereby the Eustachian tubes are opened, is shown by some experiments, of which the following may be cited.

If the mouth and nose be closed during the act of swallowing the saliva, a sensation of fulness or distension is produced in the ears; this sensation arises from the air, which is slightly compressed in the fauces, passing into and distending the tympanic cavities. Upon removing the hand from the nose, it will be observed that this feeling of pressure in the ears does not disappear, but it remains until the act of deglutition is again performed while the nose is not closed. In this experiment, the Eustachian tubes were opened during each act of deglutition: during the first act, while they were open, air was forced into the cavity of the tympanum by the contraction of the muscles of the fauces and pharynx, and the guttural orifices of the tubes remained closed until the second act of swallowing, which opened the tubes, and allowed the air to escape. That the act of deglutition opens the Eustachian tubes was inferred, also, from the custom usually adopted of swallowing while the descent in a diving bell is performed. By this act the condensed air is allowed to enter the tympanum, and the sensation of pain and pressure in the ears is removed, or entirely avoided.

The author gives an account of the Eustachian tube and its muscles in mammalia, birds, and reptiles. In some mammalia, the muscles opening the tubes appertain, as in man, to the palate; in others, this function is performed by the superior constrictor muscles of the pharynx. In birds, it is shown that there is a single membranous tube into which the two osseous tubes open. This membranous tube is situated between, and is intimately adherent to, the inner surface of each pterygoid muscle; and by these muscles the tube is opened.

The conclusion at which the author arrives respecting the influence of the closed Eustachian tubes is, that the function of hearing is best carried on while the tympanum is a closed cavity, and that the analogy usually cited as existing between the ordinary musical instrument the drum, and the tympanum, to the effect that in each it is requisite for the air within to communicate freely with the outer air, is not correct. On the contrary, the author shows that no displacement of the air is requisite for the propagation of sonorous undulations, and that were the Eustachian tubes constantly open, these undulations would extend into the cavity of the fauces, there to be absorbed by the thick and soft mucous membrane, instead of being condensed to the tympanic cavity, the walls of which are so peculiarly

well adapted to the production of resonance, in order that they shall be concentrated upon the labyrinth.

In corroboration of the above views, the author states that in cases of deafness, dependent simply upon an aperture in the membrana tympani, whereby the sonorous undulations are permitted to escape into the external meatus, the power of hearing has been greatly improved by the use of an artificial membrana tympani made of very thin vulcanised India rubber or gutta percha, which is so applied as again to render the tympanum a closed cavity.

MUSCULARITY OF THE VALVE WHICH CLOSES THE FORAMEN OVALE.

Dr. PEACOCK exhibited to the Pathological Society of London (19th Oct.) a series of preparations intended to illustrate the valve which closes the foramen ovale—a peculiarity of structure which, he thought, powerfully contributed to the permanent adhesion of this membrane, and the consequent completion of the auricular septum. The muscular character of this valve was first pointed out by Senac; it was, however, expressly denied by Haller, who remarked that the tissue composing it was purely fibro-cellular, and that the presence of muscular fibres was accidental and unusual. The examinations he (Dr. Peacock) had made, enabled him to refute the assertion of Haller, and establish the truth of Senac's doctrine. Heretofore, the explanation afforded of the closure of the foramen ovale was purely mechanical. After birth, it is said, the pressure of the blood in each auricle becomes equal, and no excess of force existing on either side of the foramen ovale, the valve is kept in contact with the edges of that aperture, to which, in process of time, it becomes solidly united. This explanation had always struck him as unsatisfactory; and, believing that muscular action was called into force for the purpose of bringing the valve in contact with the margins of the foramen ovale, he made a series of dissections, which established the truth of this opinion. Without muscular fibre, indeed, it would be difficult to explain the closure of the orifice; for, after birth, the pressure of the blood in both auricles is not so certainly equalized, for there are instances in which the walls of the left auricle are scarcely stronger than those of the right, while the cavity of the right auricle remains larger, and hence superiority of force on the right side of the valve exists, which, but for some counteracting agent, would drive the flapping membrane into the cavity of the left auricle, and prevent the completion of the septum. Indeed, there were instances in which, the muscular fibres of the valve being few and weak, the condition adverted to prevented the establishment of a perfect auricular septum, and the valve, instead of cohering properly to the margins of the foramen ovale, yielded under the pressure, and became converted into a saccular dilatation, which, as one of the specimens on the table demonstrated, projects in the form of a bag into the left auricle. Occasionally, the cellular tissue between the muscular fibres of the valve, yielded, being ruptured either by the pressure of the blood or by the action of the muscular structure; and this occurrence resulted in the formation of a cribriform septum, of which there was also a specimen on the table. This condition of the valve was generally coexistent with contraction of the orifice of the pulmonary artery. The muscularity of the valve was not apparent till after birth, and, as Senac has noticed, the muscular fibres were most marked on its left surface. In the hearts of fishes, and of reptiles, such as the turtle, the valve manifested a muscular structure more plainly than in the human subject.

In answer to an inquiry at what age he supposed perfect closure of the foramen ovale took place, Dr. Peacock stated that he was unable to answer that question; but he felt sure that if the foramen was not closed early in life, it was never closed at all; and he believed the cases were very numerous in which it remained patulous. Preparations, demonstrating the different conditions of the adherent valve and its muscularity, were handed round.

THE PROPOSED LUNACY ACT. Lord St. Leonard's Bill reforming the Law of Lunacy is under three heads:—1. For lessening the expense of the commission *de lunatico inquirendo*; to prevent the unnecessary summoning of juries; to confer upon the Lord Chancellor the right of chamber practice as regards lunatics; to prevent the unnecessary attendance of the next of kin and to do away with the references to the Masters in Chancery. 2. The consolidation of the lunacy laws. 3. The safe guardianship of lunatics.

ASSOCIATION INTELLIGENCE.

THE INCOME TAX: NOTICE BY THE CENTRAL COUNCIL.

At a meeting of the Central Council of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, held on Saturday, February 19th, 1853, Sir Charles Hastings, M.D., in the chair, it was resolved—

That the Central Council do call a meeting of the members of the ASSOCIATION, and of all other practitioners of medicine, residing in the county and city of Worcester, to assemble in the Board Room of the Worcester Infirmary, at one o'clock on Thursday, the 3rd of March, to take into consideration the subject of the Income Tax, and the importance of petitioning both Houses of Parliament, with a view to obtaining an abolition of the tax, or a more just apportionment of it.

It was also resolved—That this Council recommend the various branches of the Association to take the above subject into their consideration at their earliest convenience.

JAMES P. SHEPPARD,
Secretary to the Association.

Worcester, February 21st, 1853.

EDITOR'S LETTER BOX.

CLAIMS OF THE UNIVERSITY OF LONDON TO ELECT REPRESENTATIVES IN PARLIAMENT FOR THE MEDICAL PROFESSION.

LETTER FROM DR. SNOW BECK TO THE EDITOR.

SIR,—As the claims of the University of London to send representatives to Parliament appear, from the letter of Dr. GEORGE PATERSON in your number for the 4th of February, not to be fully understood, you will, perhaps, allow me space for the following short remarks.

As expressed in her Majesty's charter, "The University was designed to hold forth to all classes and denominations of our faithful subjects, without any distinction whatsoever, an encouragement for pursuing a regular and liberal course of education". And at the close of the communications between Lord Melbourne's Government, and the Council of University College, the Chancellor of the Exchequer (Mr. Spring Rice) thus expressed himself as to the common object:—"It should be always kept in mind that what is sought on the present occasion is an equality in all respects with the ancient Universities, freed from those distinctions and religious exclusions which abridge the usefulness of Oxford and Cambridge". And in answer to the question,—"Is it intended by Act of Parliament, or otherwise, to secure to the graduates of the new University all the professional or other privileges (not connected with the clerical profession) which are enjoyed by the graduates of the existing Universities?" he replied—"It cannot but be expedient that Parliament should hereafter, when legislative authority is required, and the intentions of donors do not preclude such a step, extend to these Metropolitan Degrees all the privileges and advantages (not of an ecclesiastical character) which are connected with degrees at Oxford and Cambridge. This, of course, applies to civil rights and professions, and not to private endowments."

The principle here laid down has been applied by the legislature, in different Acts of Parliament passed since the University of London was established. And the claim for the "privileges and advantages" enjoyed by Oxford and Cambridge, and also by Dublin, by sending representatives to Parliament, was only deferred until the constituency of the University of London had acquired that number and influence which would afford just grounds for the claim being pressed. The number of graduates is, at present, nearly 800, of whom one-third are graduates in medicine, nearly two-thirds in arts, and about one-sixteenth in laws; whilst their numbers are increasing at the ratio of nearly one hundred annually. The number of under-graduates is about 1500, to which upwards of 200 are annually added. It is therefore urged that the time has now come for giving to this considerable and increasing constituency the privilege and advantage of returning Members to Parliament, as enjoyed by the other Universities, and as guaranteed to them at the foundation of the University of London. It is also evident that the claims of this University rest upon peculiar and especial grounds.

As regards the medical graduates: many are physicians, some consulting surgeons, and a large proportion are in general practice. At least one half hold posts of responsibility in the London and country hospitals. About one third of the whole number are settled in London, and a large number in the principal towns of Lancashire and the West Riding of Yorkshire. Now it is contended that a constituency of this kind will fairly represent the feeling of the medical profession in England. And, as the members for the University of London will have no local interests to engage their attention, it is considered that the medical graduates, forming more than one-third of their constituency, will have a right to require that they should make themselves fully acquainted with medical questions, and thus represent the interests of the medical profession in Parliament more efficiently than has hitherto been the case. Should the present movement succeed, it is more than probable that the members of the University of London will be men of experience, of liberal views, and of high standing in Parliament; for the choice is not restricted to the metropolitan graduates, nor, it is hoped, will it be fettered by the qualification of property.

With pardonable partiality for his *Alma Mater*, Dr. Paterson says: "There is only one university in the United Kingdom, that of Edinburgh, in which its medical graduates would have a preponderating voice in the election of a member of Parliament, were one to be conceded to them." As stated by Mr. Disraeli in the House of Commons, in May last, there is, in the constitution of the University of Edinburgh, a great obstacle to their obtaining representatives in Parliament. This obstacle is, that the graduates are not members of the university; they have no standing in it; nor have they any voice in the direction of its affairs. The University of Edinburgh consists solely of the professors, who are appointed and controlled by the Town Council; the degree is simply an honorary certificate, which confers no corporate rights or privileges on the possessor. Hence, before the University of Edinburgh would have any claim to be erected into a parliamentary constituency, it would require to be remodelled, and its graduates incorporated as members of the university. And in the meantime, I doubt not that the present support which the movement of the University of London has received from the medical profession, will continue, based on the broad principle, that whatever tends to elevate a part of the profession tends also to elevate the whole body; and also that, through the members of this university, the medical interests will be more fully attended to in Parliament than they have yet been.

I am, etc.,

T. SNOW BECK, M.D.

February 1853.

PARLIAMENTARY REPRESENTATION OF THE MEDICAL PROFESSION.

LETTER FROM JAMES BEDINGFIELD, ESQ. TO THE EDITOR.

SIR,—It affords me great pleasure to see that you have taken up the question of "medical men in Parliament", upon an enlarged and liberal basis. For myself, I am decidedly of opinion that Dame Partington, with her mop, would as effectually check the encroachments of the ocean, as one or two members, returned by the London University, would put a stop to, or correct the existing abuses in our profession.

In the year 1834, in an address delivered in the Town Hall, Ipswich, I expressed an opinion, that until we were fully and fairly represented in Parliament, we should endeavour in vain to effect any substantial medical reform. In my address to the profession (see *Lancet*, 1841, vol. xli, p. 153), I again adverted to the subject in the following terms:—"Every sincere well wisher to medical reform must now be satisfied that there is not the slightest probability of a redress of our grievances, until we can acquire some power and influence in that House, from whence our measures have been so contumaciously ejected. It is to endeavour to persuade you to take steps for the advancement of this grand, this all-important object, that I once more address you. We may be assured, that without our own representatives in the Commons House of Parliament, no substantial good will be effected. Would it not be well for us to follow the example set us by the other professions? The interests of the church, and of the army, and of the navy, are fully represented. Even the mercantile and trading interests have their advocates and supporters; and what but our own supineness prevents us from having ours? I repeat, gentlemen, that if you desire to maintain that rank and station to which you are entitled, physicians, surgeons, and general practitioners, throughout the Kingdom, must unite, for the purpose of returning a certain number of members to the House of Commons, pledged to maintain

watch over, and protect our interests. Had we been thus supported, the late administration would not have dared to disregard our petitions for the redress of our manifold grievances, and our endeavours to procure a wise and efficient measure of medical reform."

Again, in the *Dublin Medical Press*, vol. v, p. 11, 1841, I wrote:—"But some may inquire, how is this vast power to be achieved? Again, I say, by union; by an union of the whole profession. Let it be borne in mind, that upon a very moderate computation, we are 20,000 strong; and that under the present Reform Bill, there are but few of us who do not possess a vote, which, by a little management, may be doubled, or even quadrupled; and our interest with our friends and connexions must be very small indeed, if we cannot each of us influence three or four votes more. Thus, were we but once fairly and duly organized, we might command at least 160,000 votes. Let this power be concentrated, and it will be irresistible. We have hitherto allowed ourselves to be driven like horses, and beaten like asses, because, like them, we have been ignorant of our united strength."

But I hear some exclaim, 'Funds, funds! what are we to do for funds?' Let every medical man throw his receipts of one odd day, or upon emergency, of the five odd days of every year, into one common treasury, and an ample provision will be made for every political purpose. With such a revenue as this would produce, we might return ten or a dozen members of our own—good men and true, staunch to our interests; and have also ample means left to oppose all enemies of our profession.

If we would succeed in securing such a representation in the House of Commons, as would really be useful to us, we must adopt some bold and broad measure, such as I have now recommended; in other words, instead of calling upon Hercules to help us, we must put our own shoulders to the wheel, and help ourselves.

I am, etc.,

J. BEDINGFIELD.

Longville House, Needham Market, Suffolk, Feb. 1853.

PLEURO-PNEUMONIA.

LETTER FROM F. F. GIRAUD, Esq., TO THE EDITOR.

SIR,—Since reading Dr. R. BENNETT's very interesting remarks on Pleuro-pneumonia, in the first number of the new series of the *ASSOCIATION JOURNAL*, I have been led to reflect upon my own experience of inflammatory affections of the chest, and especially upon a form of pleuro-pneumonia which has generally proved fatal in my practice.

If the following observations should lead to remarks being made, through the medium of our *Journal*, confirmatory of my own conviction of the difficulty of bringing such cases to a happy termination, I should feel some consolation; on the other hand, if any improvement in the mode of treatment should be described or suggested, it shall have my earnest attention.

In my own locality I have not perceived any marked difference in the general type of pneumonia during the last twenty-eight years: and the lessons which were taught by Laennec in his clinical lectures, on the use of tartar emetic (which I attended at La Charité, in 1823, and which are published in his work on *mediate auscultation*), I find as safe and efficient as when I first entered upon practice in this town. Heroic doses of antimony, when tolerated, are followed by speedy resolution: when they are rejected by the stomach, and unattended by any mitigation of symptoms, a low form of the disease may be suspected, and if recovery take place, it may be under the slower treatment by mercurials.

The peculiar form of pleuro-pneumonia, which I have found to be very unmanageable, and usually fatal, sets in with slight rigors, uneasiness in the limbs, and a dull pain in the right side, very low down, and as near as can be conceived to the convex surface of the liver. There is no indication of pneumonia on auscultation; a short cough, with common bronchial expectoration, constitute the chest symptoms: and these, in about twelve hours, are followed by increased pain and difficulty, rather than by shortness of breathing. The pulse becomes a little accelerated, and the tongue is usually milky white; the commencement of pneumonia is now indicated by the crepitating râle being heard over a small extent of the lower part of the right lung, the expectoration also assuming the characteristic appearance. The first bleeding usually displays a slightly buffy condition of the blood; but, as the disease advances, a second abstraction of blood shews a coriaceous surface easily broken down, and great prostration of strength attends both the commencement and the progress of the attack.

Antimony is seldom tolerated, and when it is, only temporary relief is afforded, a sudden increase of pain often coming on in the side, with corresponding depression of the vital powers. I have found the same uncertainty in the effect of mercurial treatment, both inunction and doses of calomel with opium failing to affect the mouth, or mitigate the symptoms.

From five days to a week has been the usual duration of fatal cases. The *post mortem* appearances, in the few instances where an examination has been permitted, have shewn effusion of sero-purulent matter between the base of the right lung and the diaphragm, with patches of lymph covering the pleura reaching only to a small extent, also consolidation of the lowest parts of the right lung; the remaining portions of the lungs being unaffected.

The peritoneal covering of the diaphragm, as well as that of the liver immediately below the affected parts of the pleura, have displayed a highly vascular appearance, but without any carpeting of lymph.

The peculiarities in these cases are, the limited extent of pleuro-pneumonia, and its insidious mode of attack, the great prostration of vital power, and also the previously healthy condition of the patient, not weakened by age or infirmities.

I am, etc.,

FREDERICK FRANCIS GIRAUD.

Faversham, Kent, February 1853.

THE INCOME-TAX.

LETTER FROM DR. NANKIVELL TO THE EDITOR.

SIR,—I trust that the importance of the subject at the present juncture, and the necessity for prompt and collective efforts on the part of the profession, will excuse my again urging my professional brethren to lose no time in sending petitions against the existing form of income-tax, from every town throughout the country.

Nothing can be more easy than such a course. Now that Parliament has met, there is no object in making direct application to the Chancellor of the Exchequer. It is only necessary for the medical men, in each town or district, to adopt or modify the petition published in the *ASSOCIATION JOURNAL* of Jan. 18th; to obtain as many signatures to their petition as can be obtained *speedily*; and to forward it, without delay, to the members of their town or county, with a request that it be immediately presented to the House of Commons.

The effect of such a course will be the immediate and timely presentation of a large number of petitions to the House, and the enlisting of almost every English representative in presenting these petitions.

The desirableness of this course is obvious, from the well-known fact, that the legislature is much influenced by the number of petitions, and the number of members presenting petitions, on any one question. Now is the time for the profession to make one united, prompt, and strenuous effort, to rid themselves of this great injustice. After Easter, the income-tax will be either altered, or made permanent in its present obnoxious form.

It is surely also desirable that the Central Council, and the Councils of the various Branches of the Association, should petition against this impost, so unjust and oppressive to its members.

I am, etc.,

C. B. NANKIVELL, M.D.

ERRATUM. In our last number, Dr. SMITH was, by an error of the press, called "CHAIRMAN", in place of "SECRETARY", of the Income-Tax Committee of the Association. Dr. MALDEN, of Worcester, is the Chairman of the Committee.

NEWS AND TOPICS OF THE DAY.

ROYAL COLLEGE OF PHYSICIANS. At a Comitia Majora Extraordinaria, held on Thursday, the 17th instant, Dr. Ramskill, of St. Helen's Place, Bishopsgate, having undergone the necessary examinations, was admitted a Licentiate of the College.

MEDICAL SOCIETY OF LONDON. The Annual Anniversary Oration of this Society will be delivered by Dr. Snow, on March 8th.

HOSPITAL FOR DISEASES OF CHILDREN. At the annual meeting, Sir H. Dukenfield in the chair, it was stated that the number of out-patients numbered 1250, and all the beds were generally full. The subscriptions figured £293; the donations, £4221, including £100 from Her Majesty.

NAVAL ASSISTANT-SURGEONS.

(House of Commons: Committee of Supply, February 21.)

Colonel BOLDERO reminded the committee that in 1850 he advocated the cause of the assistant-surgeons, and carried a resolution which declared that the accommodation provided for them was inadequate and insufficient for securing the full benefit of their professional services. He was anxious to know what were the views of the present Board of Admiralty? The Lords of the Admiralty issued a memorandum on the 17th of July, 1850, which was not calculated to give effect to the resolution of the House. The memorandum was, indeed, extremely offensive to that class of officers, and was considered an insult to the whole medical profession. According to that memorandum they were to be allowed cabins only when the space on board would admit of it. This last exception would leave the whole matter to the Board of Admiralty, and defeat the resolution which the House had passed in 1850. He had received returns from the Mediterranean station, and out of twelve assistant-surgeons who had passed through all the ranks of their profession only five had received cabins; and only two had those little advantages which were enjoyed by the other officers in the ward-room. The result of this was that the *élite* of the candidates at the London, Edinburgh, Glasgow, and other colleges shunned the navy. In the event of a sudden war, where would the Government obtain assistant-surgeons when such was their treatment? How could Government expect candidates for medical situations in the navy when for three years they must remain in the cockpit, where study was next to impossible? What was the effect of such a system? Mr. Guthrie, in his lectures, said that medical officers could not be found qualified for the navy, and that the system adopted by the Admiralty, instead of raising the value of the service, deteriorated it by employing persons of an inferior description. Was it desirable that they should continue a system which disgusted young men, and deterred them from entering into the naval service? It was even more necessary that there should be well qualified surgeons in the navy than in the army. The sailors depended entirely upon the assistance of medical men, and, if those men were such surgeons as were employed in 1809, what confidence could the service have in them?

Admiral BERKELEY would ask the hon. and gallant officer how he would like, as the colonel of a regiment, to have the discipline of his regiment and the internal arrangements of his regiment regulated by a naval officer? That was really the question. Admiral Berkeley affirmed that very great improvements had taken place on board ship, and that great additional accommodation had been afforded to the medical officers attached to the naval service. The Board of Admiralty had done all that was possible to carry into effect the resolution of April, 1850, and he expressed his regret to find the hon. and gallant officer doing so much to create dissatisfaction in the navy by his efforts to place the assistant-surgeons above their superior officers—the mates. The fact was, that the assistant-surgeons were, on the whole, very well off; and, so far from there being any want of candidates, no fewer than fifty-four had entered within the last few months.

Mr. HUME said, that the question was whether the navy ought not to obtain as able and efficient medical assistance as the army. He could see no reason why both officers and men in the navy should not receive the best medical talent that was to be had; which, however, was impossible so long as the assistant-surgeons were treated as at present.

Mr. OSBORNE said that the resolution of April, 1850, to which the hon. and gallant officer had referred, was carried by surprise in a thin house of eighty-eight members. He contended that for many years past there had been no class of men whose comforts had been more attended to than those of the assistant-surgeons. In 1840 a commission, composed of the Duke of Wellington, the Duke of Richmond, Sir George Cockburn, etc., reported that there were practical difficulties in the way of allowing the assistant-surgeons in all cases to mess in the ward-room; but that this was less essential, as they had ascertained that the accommodation afforded them of late years was so improved as to render it unnecessary for them to make any recommendation in that respect. The hon. and gallant officer had characterized the memorandum of July, 1850, as an insult to the medical profession. The recommendation of that memorandum was, that the assistant-surgeons should be allowed cabins where space would admit of them. He (Mr. Osborne) could not see where there was any insult in that. (Hear.) He found, from a return furnished in May, 1851, that the recommendation of the Board had been carried out in all cases, except where it

had been found utterly impossible; and what more would the the hon. and gallant officer have? (Hear.)

Colonel BOLDERO assured the hon. and gallant admiral (Berkeley) that nothing was further from his intention than to create dissatisfaction in the navy, and that he had taken up the question solely as a matter of public duty. (Hear, hear.)

Captain SCOBELL was astonished how the Admiralty had found it practicable to find cabins for so many. Cabins were impediments to clearing for action. There were other classes—such as the mates, who would be our future admirals—struggling upwards, who had claims for cabins as well as the assistant-surgeons, who were, no doubt, a very respectable class of men; but it must be considered that a ship was like that house—if all were to have seats, there would be no room for them.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. IX.

LONDON: FRIDAY EVENING, MARCH 4, 1853.

NEW SERIES.

THE LAWS AND ETHICS OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

In the Royal Charter of Incorporation granted to the Medical and Chirurgical Society of London, by his late Majesty William IV, we find the following clause:—

“Our further will and pleasure is, that the Fellows of the said Society shall, and may, on the first day of March one thousand eight hundred and thirty-five, and also on the first day of March in every succeeding year, or as near the same as conveniently may be, assemble together at the then last or other usual place of meeting of the said Society, and proceed by method of ballot to nominate and appoint a President of the said Society, and such Officers and other Members of the Council as may with the President form the number of twenty-one, of whom we have willed that the Council shall consist.”

The plain meaning of this clause is, we apprehend, that the nomination and election of the President, Office-bearers, and other members of the Council shall be made by the Fellows of the Society, annually, on the first of March. Unfortunately for the Society, this excellent provision of the Charter is systematically violated every year, and the choice of the President and other Office-bearers is usurped by the Council, and entirely taken out of the hands of the general body of Fellows, who have no alternative left but to absent themselves in displeasure, (as many do), from the scene of the mock elections, or to attend as mere spectators, or listlessly deposit in the ballot-box the printed lists prepared by the Council. Remonstrance has proved vain; and even the discussion of the grievance has been stifled or eluded at the annual meetings, the only occasions upon which such questions can be mooted, as they are the only occasions upon which the Council comes before the Society with an account of its stewardship. In these circumstances, we offer no apology for at once carrying the subject beyond the walls of Berners Street into the freer arena of public professional discussion.

We may possibly be told by a few persons of peculiar mental idiosyncrasy that we are labouring under a complete mistake, and that the annual elections on the first of March are real elections to office by the Fellows, of those colleagues whom they wish to honour. To such a statement we have no hesitation in offering a direct and emphatic negative, and supporting it by facts, in any place and at any time that our opponents may select. However objectionable or unpopular a nominee of the Council may be—and occasionally very objectionable persons have been nominated to office—it has been found practically impossible for a majority to give effect to their objections. A dissentient majority are powerless, unless they combine in favour of *one selected person*, in room of him whom they wish to erase from the printed list. This would necessitate meetings, correspondence, and canvassings, involving an amount of annoyance and loss of time, more than sufficient to compel submission on the part of busy and peace-loving professional men.

The following is a copy of the Bye-law, by which the provision, in favour of the elections being made by the whole body of Fellows, has been *de facto* nullified.

“Balloting lists recommended by the Council, and having blank spaces for such alterations as any Fellow may wish to make in them, shall be laid on the Society’s table, for the use of the Fellows, and sent to each resident Fellow with the circular summons.”

The excellent reform in the method of balloting for Fellows which was suggested on Tuesday by Mr. CHARLES HAWKINS, viz., that in future they should be balloted for individually, and not collectively, as at present, would, if applied to the Council nomination list, be a step in the right direction. It would at least give to the Fellows the power of a *veto*; though it certainly would not put them in possession of the prerogatives of nomination and election, to which they are as clearly entitled by the Society’s Royal Charter, as is any parliamentary constituency to the unchallenged right of nominating candidates, and then electing the most acceptable from those who have been nominated. It appears to us, in fact, that the Bye-law is so directly opposed to the letter and spirit of the Charter, as to be positively illegal, and to require the interposition of a court of law, if it cannot otherwise be got rid of. We are glad to know that it is the intention of some Fellows to obtain the opinion of eminent counsel upon this point.

The practical evils which flow from the elective franchise having been wrested from the Fellows by the Council, was well illustrated by the disclosures elicited on Tuesday by the question proposed. It ought surely to have been possible for the Fellows to have expressed, by the ballot, an opinion as to the validity of the unwritten Bye-law, by which it appears the Council are regulated in compiling their list of nominees. The responsibility should not have been allowed to remain with a virtually self-elected Council of declaring that, although Dr. MURPHY, and others unconnected with a London College, may be allowed to contribute as Fellows to the funds, they cannot, however high their private character and scientific station, be permitted to rise to posts of honour in the Society. The profession would, we imagine, be glad to know if a doctrine so ungenerous is received, or is repudiated by the Fellows at large; and many gentlemen who are now thinking of joining the Society may wish to have information on this important point, before they voluntarily enter a community which is governed in opposition to the spirit of the times, in opposition to the provisions of its Charter, and actually in ignorance of its own mind upon the most vital questions.

It is very clear that matters cannot long continue as at present. The tension of feeling is so great as to require relief; and either a reform or a revolution must soon solve the difficulty. Till the voice of the Fellows be heard in the elections, and in pressing questions of internal discipline, distrust must continue to endanger harmony; and what might, under more generous auspices, become the freest field in the world for scientific emulation among the pro-

fessors of legitimate medicine, must continue to be a circumscribed club, labouring under the heavy scandal of permitting the homœopathy of Dr. Henriques and Dr. Gully to remain uncensured, while the want of a London title has been found sufficient to deprive Dr. Murphy of that preferment to which he is so richly entitled by his seniority on the list of Fellows, by his upright character, and by the excellence of his professional position.

On leaving the meeting on Tuesday, we could not help feeling that it would have been a more hopeful omen for the weal of the profession, and for the future prosperity of the Royal Medical and Chirurgical Society, than the disclosures with which the proceedings opened, had the President been able to add to his interesting sketches of deceased Fellows, a passage similar to that which we subjoin, spoken on a similar occasion by Dr. BEGBIE, a Member of our ASSOCIATION, from the chair of the sister Society of Edinburgh.

"I would willingly," said Dr. Begbie, "have been spared the occasion of referring, even for a moment, to other losses than those we have sustained by the hand of death. Our own act—justified by a stern necessity, and imposed upon us by a due regard to the interests of science, and the honour of our profession—has severed from us some who were our late associates in the business of the Society, all of whom we would have gladly retained, and none of whom we can afford to lose; but they were not of us. They had abjured the faith in which they were educated, and in virtue of which they had obtained status, and honour, and emolument; they vilified the doctrines which they once taught, the teachers whom they delighted to honour, and the brethren with whom they took counsel together; they absented themselves from the colleges, and societies, and convivial meetings, in which they once took delight; they waged war against their quondam friends, and against their former selves; and all this without a vindication, or, at best, with but a feeble and abortive attempt so palliate their conduct. The patience and forbearance which we long manifested, were exhausted and overcome; and, by an almost unanimous voice, we declared them no longer members of the Medico-Chirurgical Society. We commiserate their position; we lament the injury done through them to a noble profession; but we rejoice in the hope that the age which has seen the rise of this fatal apostasy, may, long ere its close, witness its decline and downfall, when, after years of penitence, our alienated brethren may be received again into the fellowship and the privileges which they have so recklessly sacrificed."

THE MEDICAL DIRECTORIES FOR 1853.

We have this year two Medical Directories, rival claimants for the support of the profession. In reference to this rivalry it is possible that there may be some truth in the following sentences of the preface to the elder of the two publications:—

"Divide the interest and you spoil the work. Each man must make his return annually to ensure correctness; and if some return to one, and some return to the other, both must be failures."

When we come to have an official register of the qualified medical practitioners in all parts of the kingdom, we shall not require such publications as these; or if they should still appear, their rivalry will no longer be injurious, for each will have an authentic list to proceed upon, by reference to which accuracy and trustworthiness may be tested. But in the absence of any such official list, and of the power of compelling medical practitioners to send in

returns, we cannot but regret to see efforts and energies which should have been brought to bear upon a common object, wasted to the injury of both publications, in what, from the language used on both sides, there is too much reason for regarding as a mere personal competition.*

The ostensible reason for bringing out another Medical Directory, in opposition to that which has now reached its eighth annual issue, is, that quack advertisements and the names and titles of persons, who have sullied their legal qualifications by engaging in the practice of the homœopathic and hydropathic quackeries, were permitted to appear in the latter. We can, to some extent, admit the sufficiency of this reason. The omission of the quack advertisements from the elder Directory was loudly called for; but we can only see evil in retaining the names of homœopathic practitioners, and omitting their titles and qualifications; which were beacons by which legitimate practitioners could avoid these degraded men. To omit the descriptive titles, and yet retain the names of homœopathic practitioners, is, in our opinion, a false step which cannot too soon be rectified.

The proprietor of the elder Directory at one time intended to distinguish homœopathic practitioners by an asterisk prefixed to the name. We regret that this intention has not been fulfilled. If the public wish to indulge in quackery, they are never at a loss to find out the quacks, and do not require to have recourse to a Medical Directory for their addresses. But medical men are not always aware with what sort of persons they may be suddenly brought into communication and correspondence in the course of their practice; or into what hands their patients leaving home for a time may inadvertently fall. So far, therefore, from being a guide to homœopaths, the distinguishing asterisk might have proved a beacon to insure their being avoided by respectable practitioners.

But we have more serious fault than this to find, especially with the elder Directory. In their preface it is said, that—

"In obedience to a loud and general outcry against homœopaths, their publications and their appointments, we have deemed it our duty to suppress all mention or allusion to such obnoxious matter: and it will be found that the names, addresses, and qualifications of such practitioners are alone given."

On reference to particular names, however, in the elder Directory, this does not prove to be strictly the case. Homœopathic appointments and publications are indeed generally suppressed; but whatever may have been written, and whatever public distinctions may have been attained by homœopaths before they fell from the ranks of legitimate practice, are still given. Thus all trace of their offence is obliterated, and whatever testimonials of character they may have been able to possess themselves of before its commission, are allowed to appear and mislead the public and the profession. One gentleman, we observe, from his share in the translation of Jahr's notorious handbook, is actually designated "co-editor of a new materia medica", as if the work had been a legitimate publication. These blunders must be carefully guarded against in future, if the work complained of is to retain any place in the confidence of the profession.

And this leads us to observe, that it would be a great im-

* Vide the respective prefaces, and the weekly Journals of the rival proprietors for the last six or eight months.

provement, and enable the book to be sold at a lower price, if the practice of soliciting medical men to furnish a list of their publications were discontinued. The case may indeed occur between individuals of the same name, where it is desirable to distinguish the author of a particular work of high and acknowledged merit. But what does the profession care to know that Mr. A. has published a case of tetanus; that Mr. B. is a "contributor to the Medical Journals", the extent of his contributions being left to be inferred from the very vagueness of the terms in which they are stated; or that C. does not confine his lucubrations to medical subjects, but dabbles in theology or poetry? We might cull some very choice instances of this kind of information from the work before us; but we refrain, as we do not wish to wound the feelings of individuals, although, in point of fact, the individuals sending in such silly returns are as much to blame as the editors.

We would also recommend that the lists of appointments should be confined to such as are strictly public and of a purely professional nature. In both these particulars the contributors and editors of the Medical Directories have grievously offended. We have the names given us of insurance companies to which gentlemen happen to be medical referees; of clubs and friendly societies to which they are surgeons; and appointments, not even connected with the medical profession, are mentioned, such as that of deputy-lieutenant. Can any of our readers inform us what it is to be "surgeon to the Ancient Order of Shepherds", or to the "Loyal Society of Ancient Britons"? Sometimes, too, titles and appointments which do not indicate any high professional standing are given in a slightly altered form, so as easily to be mistaken by the uninitiated for something higher. Thus one gentleman, and he a homœopath, appears as "Fell. Roy. Phys. Soc. Edin.". This does not refer, as many might suppose, to the Royal College of Physicians, but to the Royal Physical Society of Edinburgh, a society consisting chiefly of students; and which, moreover, does not confer the title of Fellow. Another calls himself "late Assist. Phys. to the Royal Infirmary, Edin.", when, in reality, he was, in the language of the institution, "physician's clerk". These are but specimens of many similar returns, in which we do not think that sufficient care has been taken to prevent the public from being misled, as the faults to which we now refer have, in former years, often been made subjects of remark in the medical journals.

The Royal College of Surgeons of England has lately been found fault with, and very justly, for proposing to license in midwifery parties who have no legal qualification to practise. But according to the Medical Directories the number of licensing boards in midwifery far exceeds any conception we could have formed on the subject. We have "Accred. Accouch. Schol. Art. Obstet. Edin." "Lic. in Midwif., Edin." "Lic. Accouch., Glasgow Lying-in Hospital". But Dublin is peculiarly prolific of such bastard titles. The Incorporated Lying-in Hospital—the Coombe Street Lying-in Hospital—the Anglesey Lying-in Hospital—all have their licentiates, accoucheurs, and certified practitioners in midwifery! Now it ought to have been known to persons editing works of this sort, that there are no such legal titles; that they are merely certificates of diligence, or of attendance on a few cases; and that to represent them in any other light is to confound the distinction between certificates of merit or mere attendance, and legal qualifications to practise.

It will thus be seen that there is much room for improvement in the principles and plan, in accordance with which Medical Directories are at present compiled.

Difference of opinion will doubtless exist as to whether the elder or the younger Directory is the best. The latter is the most convenient, as all the names of British practitioners are arranged in one alphabetical index in place of being, as in the other Directory, classified in three departments, viz., Metropolitan, English Provincial, and Scottish. As to "the defilement of quackery", from which the younger Directory professes to be free, we will only remark that we can see no well marked difference between the treatment of quacks by the rival editors. Both mingle their names and addresses in undistinguishable confusion with those of honourable men.

ASSOCIATION INTELLIGENCE.

METROPOLITAN COUNTIES' BRANCH: NOTICE OF GENERAL MEETING ON THE SUBJECT OF THE INCOME-TAX.

REQUISITION. To the President, Secretary, and Council of the METROPOLITAN COUNTIES' BRANCH of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

We, the undersigned Members of the Metropolitan Counties, Branch of the Provincial Medical and Surgical Association, deeply impressed with the injustice to members of the medical profession of the Income-Tax, do hereby request you to call a Special General Meeting of the Members of this Branch, to consider the propriety of petitioning both Houses of Parliament against the Income-Tax as at present levied, and of appointing a Committee to co-operate with the Income-Tax Committee of the parent Association, nominated at Brighton, and re-appointed at Oxford:—

T. SNOW BECK, M.D., Langham Place.
J. RISDON BENNETT, M.D., Finsbury Square.
JAMES BIRD, M.D., Hyde Park Square.
C. COGSWELL, M.D., Bernard Street, Russell Square.
WHITE COOPER, F.R.C.S., Berkeley Square.
JOHN ROSE CORMACK, M.D., Putney.
RICHARD PAYNE COTTON, M.D., Clarges Street, Piccadilly.
JOHN DAVIDSON, M.D., Wilton Place, Belgrave Square.
ALEXANDER HENRY, M.D., Alfred Street, Bedford Square.
HENRY LEE, F.R.C.S., Dover Street, Piccadilly.
WILLIAM O'CONNOR, M.D., George Street, Portman Square.
J. J. PAUL, M.D., Putney.
R. HUTCHINSON POWELL, M.D., Edwards Street, Portman Square.
WILLIAM RICHARDSON, M.D., 17, Radnor Place.
BENJAMIN RIDGE, M.D., Putney.
C. H. F. ROUTH, M.D., Montague Square.
R. H. SEMPLE, M.D., Torrington Square.
CHARLES SHILLITO, M.R.C.S., Putney.
FRANCIS SIBSON, M.D., Lower Brook Street.
THEOPHILUS THOMPSON, M.D., Bedford Square.
H. HAYNES WALTON, F.R.C.S., Brook Street.
R. HARLAND WHITEMAN, L.S.A., Putney.

At a Meeting of the Council, held this day, it was resolved, in compliance with the above requisition, that a General Meeting of the Members of the Branch shall be held on Tuesday, the 15th inst., at 37, Great Queen Street, Lincoln's Inn Fields, at 4 P.M. precisely, for the above mentioned purpose; and also to recommend to the Branch to petition both Houses of Parliament in favour of granting the parliamentary franchise to the University of London.

T. OGIER WARD, M.D., *Hon. Secretary.*

March 2nd, 1853.

ORIGINAL COMMUNICATIONS.

INFLUENCE OF NOXIOUS EFFLUVIA ON THE ORIGIN AND PROPAGATION OF EPIDEMIC DISEASES.

By R. D. GRAINGER, Esq., Lecturer on Physiology at St. Thomas's Hospital.

(Concluded from p. 166 of last number.)

II. INFLUENCE OF EFFLUVIA ARISING FROM PRIVIES AND CESSPOOLS.

It is the remark of an acute observer, that one of the best tests of the progress which a people have made in civilization, is furnished by the manner in which they dispose of their excreta. That this observation has a foundation in truth, is amply shown, independently of what we see going on around us, by the accounts received from India and other semi-civilized countries. Often as the evils arising from the cesspool system have been forced on the public attention, I feel assured that they are still but most imperfectly apprehended. Some glimmerings of the truth have indeed broken into the darkness: we do not now-a-days hear many of the ancient eulogiums on cow-stalls, horse-dung, and similar remedies, once popular, and not, as I know, yet extinct. The painful experience of the present winter has likewise convinced the higher classes in many parts of the provinces, that they are not exempt from the dangers of the poisonous effluvia which daily decimate the poor in their neglected abodes. Owing to the increased attention now paid to sanitary inquiries, and the warnings of our own profession, the public are beginning to comprehend that much of the ailing and sickness and diarrhoea, to which children, especially in large towns, are subject, and which are often attributed to "bilious attacks", are in reality dependent on the malaria arising from cesspools and foul drains. Another and more widely diffused error is, that because no odour or stench can be perceived, no injurious effluvia can be present; but it is important to point out that poisonous gases may be present in quantities quite sufficient to injure the health, and yet without affecting the senses. I had a curious proof of this a few years ago, when inquiring into the disinfecting properties of the nitrate of lead. On visiting the Fever Hospital, the wards were found to be, as they always are, scrupulously clean, and perfectly devoid of smell. The day of the month was written on one of the walls with the colourless liquid; and, on examining the writing next day, the letters had become evident by their dark colour, owing to the presence in the air of sulphuretted hydrogen, and the consequent formation of sulphuret of lead.

The effluvia from cesspools, when concentrated, afford a marked illustration of the principle already noticed, that any one of the predisposing causes of epidemic disease is capable, according to circumstances, of developing all the principal members of the class: but the extended inquiries of late years have shown, that affections of the abdominal organs are specially liable to be thus induced. Gastric fever, of a low character, and often of the remittent type, vomiting, diarrhoea, dysentery, and cholera, are the constant results of what may be termed the *privy atmosphere*. There is no point on which there is a more unanimous agreement among the practitioners in populous districts, than on this; or on which I have received more full and precise evidence. Among other indications, I may mention that, in various parts of the kingdom, it has been noticed that the families in courts and alleys who live immediately opposite to or over privies, suffer much more from the epidemics just specified, than those more remotely located. Houses in this position often become so notorious as the habitation of fever, diarrhoea, cholera, etc., that the people avoid them; and from this cause alone, I have frequently seen such dwellings tenanted. That the same cause operates, and in the same manner, wherever it is present, was abundantly proved during the cholera epidemic.

On these points I have lately obtained a large body of exact information. In the city of Norwich, it is a common custom, even in the most respectable houses, to have large cesspools in the cellar or basement, frequently of enormous size, some of them being 60, 80, and 100 feet deep. The effluvia were often most overpowering; and in every instance in which an inquiry was made, I found that the inmates, and especially the children, who always suffer more than adults, had laboured under vomiting, diarrhoea, low remitting fever, etc., which were attributed by the medical attendants to the malaria thus arising. The correctness of this opinion has been lately confirmed in a most satisfactory manner. The local authorities, acting under the Public Health Act, have, in a large number of instances, removed the cesspool, and substituted a cleanly water-closet for the filthy privy; and in all the cases where I instituted inquiries, it was found that the health of the inmates had improved in a marked degree, and especially that the gastric and febrile disturbance had ceased.

A similar instance of the evil and the remedy, but on a smaller scale, was mentioned to me by my friend Mr. Collett, of Worthing, to whom I am indebted for the following details, the like of which might be adduced in a multitude of other examples. Mr. Collett says:—"From 1838 to 1842, I was in constant attendance on the families of the Coast Guard station, who occupied ten houses, each containing four rooms; the inmates averaging six in each dwelling. These people were in very comfortable circumstances, the men earning from 18s. to 24s. per week. These details are given to show that destitution could not have existed. These families were attacked with remittent and typhus fever; and it is important to remark, that the women and children, who were more or less at home during the day, and of course at night, were the principal sufferers, and to such an extent, that, in almost every house, one or more of the inmates were frequently under medical treatment: the men, who were much from home, for the most part escaped." On seeking for the cause of this obstinate and localised attack, Mr. Collett satisfied himself that this proceeded from an open ditch without any outlet, into which the privies emptied their contents, situate at the rear of the houses, and emitting, of course, offensive effluvia. After great difficulty, he succeeded in having the ditch properly drained, covered over, and provided with an outlet. Some low, marshy ground, between the houses and the sea, was also drained. A period of nine years has elapsed; and, although epidemics, principally attributable to similar local causes, have occasionally prevailed, the buildings in question have altogether escaped, and no persons can be more healthy than their inhabitants.

The escape of the men in this case, owing to their absence from home, reminds me of a similar exemption, but on a much larger scale, which occurred at Berlin, during the cholera of 1848. A body of 6,000 men, artisans and labourers of all classes, and residing in different parts of the city, were employed in the open country in some public works: they were absent from home fifteen or sixteen hours daily, only returning to sleep at night. These men were so remarkably exempt from cholera, only eight of the whole number being attacked, as to attract general attention; and the only explanation that could be given was, that they were for nearly two-thirds of the twenty-four hours withdrawn from their crowded homes; while their families, remaining, suffered in the same degree as the inhabitants in general.

During the late unprecedented season, several towns, as well as rural districts, have been attacked most severely with low fever, which, in all the cases I have inquired into, has been more or less of the gastric type, and attended with diarrhoea. That the effluvia from cesspools and drains have been, in addition to the excessive moisture and high temperature, the more immediate predisposing cause of this epidemic, is the decided opinion of all the practitioners in those towns which I have officially visited. One peculiarity which has attracted very general attention, is, that the higher classes and tradespeople have suffered almost entirely

on the whole, however, more than the poor, although that has been asserted.

With the view of illustrating the subject under consideration, I propose to describe the attack which occurred in the months of November and December, among the higher ranks at a bathing-place on the south-western coast; and this selection is made, because, so far as could be ascertained, there was but one predominating cause to which the outbreak could be attributed. It must be premised, that in the above town, there is no system whatever of sewerage; the water-closets and privies having nothing but cesspools to receive their contents. Many of the first families were attacked, two or more of the inmates sometimes suffering; and several deaths occurred in some of the principal terraces and streets, where the rent and taxes of unfurnished houses were often as high as £60, £80, and £100 a year. Owing to the excessive rain, and the absence of deep drainage, many of the houses, villas, etc., had become flooded in the basement floor, the consequences of which may be gathered from the description of a newly erected terrace, where I was taken by a physician in large practice. In the basement, which was entirely undrained, were placed the kitchens, and at the back, and on the same level, was the servants' privy, and the cesspool of the water closet. All this was flooded; the water had risen as high as the seat of the privy; the cesspool had overflowed; the soil had consequently been washed into the kitchens, causing a horrible effluvia. This had taken place very generally elsewhere; and the nuisance thus caused was so great, that the medical attendants could distinguish by the smell, on first entering, when the house was flooded. In one of the first-rate houses which I examined, and where the gentleman had suffered from fever, the stench from the drains leading to the cesspools was so overpowering, that the whole house was filled with it whenever the plug, which had been applied to pen in the poisonous gases, was withdrawn. In the course of the inquiry, I visited several houses of this class, where there had been fever; and in every case the privy effluvia was intense, and was assigned as the cause of the attack. The same marked influence of these emanations was noticed among the principal families at a town in South Wales, the whole subsoil of which is so soaked with cesspool matter, that in the best parts of the town, foul percolation has taken place into the wells, to such an extent, that maggots have been found in the water. Whenever there is much rain, regurgitation occurs; the drains and cesspools overflow, filling the houses with effluvia, to which both the sufferers themselves and their medical attendants attributed the gastric fever which prevailed at the time of my visit.

The instances now adduced plainly show, that wherever human beings, whether poor or rich, are exposed to the privy atmosphere for a sufficient time, and in sufficient intensity, their health inevitably suffers, from a degree which may amount only to what is called "ailing"; to nausea, dyspepsia, and diarrhoea; or to low fever, usually of the gastric type, often remittent; to obstinate and fatal diarrhoea and dysentery; or, when present, to cholera.

But it would be taking a very imperfect view of the influence of this deleterious agent, to suppose it only induces gastric derangement and fever: the whole system suffers, and pre-eminently in children, those delicate tests of preventible disease. As one of the more elucidative instances of such affections, and indeed of the whole subject, I may perhaps be permitted to quote the case of Christ Church Workhouse, belonging to the Whitechapel Union, although it is already recorded in my report on cholera.* In this establishment, 400 children were lodged; and, separated from it by a narrow lane, was a manufactory of artificial manure, where night-soil and putrid blood were desiccated, causing a horrible effluvia in the workhouse, and inducing a large amount of diarrhoea. During the cholera, two outbreaks of diarrhoea were directly traced to these effluvia, each following the renewal of the manufactory, which had

for a time been checked by legal proceedings. But, besides this, Mr. Byles, to whom I am indebted for these particulars, states that, whenever the wind blew from the works, fever of an intractable and typhoid form prevailed; and that measles, small-pox, and other infantile diseases, assumed a typhoid tendency. He also states—and to this point I would call special attention—that a most unmanageable and fatal form of aphthæ of the mouth and genitals, running rapidly into gangrene, was so prevalent, that, in one quarter of the year, twelve infants died from it. These attacks were referred by Mr. Byles to the poisonous effluvia; and that he was correct in his opinion, was proved by the fact, that when, after repeated attempts to remove this monster nuisance, and after many lives had been sacrificed, the manufactory was finally closed, the health of the whole establishment was so greatly improved that, up to the date of the report, not a single death occurred among the children, except from chronic disease. I have recently been informed by the medical officer of the town in Wales to which I have alluded, that he has found the same gangrenous disease in infants, in filthy and overcrowded houses.

III. SANITARY IMPROVEMENTS.

After the consideration of so many painful topics, the question suggests itself—Is all this evil, this misery, this degradation, necessary? Is it a condition of our existence that these desolating fevers—these exhausting diseases, which sicken and destroy the infant just entering upon life, and sap and undermine the vigour of manhood,—should arise, and persist, notwithstanding all efforts for their removal? The answer to this all-important query is to be found in the definition of the predisposing causes of epidemic disease. Poisonous effluvia, polluted water, putrid food, are without: they exist accidentally, and form no necessary part of man's nature. We now know precisely how they are generated, and how they act, and we perceive how they may be removed. It is indeed remarkable, that any doubt ever should have existed in intelligent minds on the subject; for it is obvious that the inquiry is infinitely more simple than many of the problems presented by morbid affections, arising from internal causes. The phenomena are palpable—gross, they might be termed—both physically and metaphysically; their causes are patent, and force themselves on the most ordinary entrance to knowledge—the senses; the consequences are more constant, direct, and definite than usually present themselves in any recondite investigation. Causes, conditions, and results are known; what else is requisite for a scientific and successful research? It has, in fine, become evident to all who are familiar with the process of inductive knowledge, that the whole question is ripe for solution. In this communication, allusion has been made to the ignorance, and consequent incertitude, that have prevailed in regard to this subject; but in the interests of humanity, and in vindication of that exalted science which it is our happiness and privilege to profess, it must be declared that among the physicians and surgeons personally acquainted with the diseases of the poor, not as they are studied in the wards of a hospital, but as they are revealed in fetid courts and stinking houses, there never has been any doubt. Dr. Ferrier, when, on entering a close and crowded room, he, to bring relief to the victim of fever, thrust his cane through the window, has typified the whole category of sanitary evils and sanitary remedies. I have myself seen, within the last three months, two instances essentially the same, where the medical attendants had actually had holes cut in the walls of houses with no outlet at the back, in order to admit fresh air to typhus patients. Let the public, then, know that medical science, even from the remotest ages, has pronounced its decision.

As we are speaking of opinions, reference may be made to one which indicates some strange obliquity, and which has always suggested to my mind the painful truth that, in our fallen estate, we love darkness rather than light. Medical men, when they advocate measures calculated to promote the public health are often suspected, and have in

* Report of the General Board of Health on Epidemic Cholera, 1849. vol. II, p. 88.

a thousand instances been directly charged with sinister motives. It much concerns the common weal, that the public should comprehend that this is their question, not ours; nay, it is the very reverse; for, in promoting efficient sanitary reforms, the medical practitioner labours to secure that which, if attained, must, as no one foresees so clearly as himself, involve a sacrifice of his pecuniary interest. To the worldly minded, such a disinterested spring to action is not only incredible, but incomprehensible; and, therefore, they reject it as a thing impossible. True it is that such lofty motives are not natural to men: they have their origin in purer sources—in the liberal studies that refine and elevate the mind—in the communion held with God, through the observation of His works—and above all, in the spiritualising influences of the Gospel of peace, which, while it declares it to be more blessed to give than to receive, commands us to look on the things of others rather than on our own.

Having been led to touch upon this topic, I would offer some homage, demanded by truth, to this elevated spirit of self-sacrifice. From the office which I have had the honour to hold, constant opportunities have been presented to me of witnessing the generous and uncalculating zeal with which, in the midst of every kind of discouragement, often coming from the most powerful and influential quarters, the members of our common profession, in all parts of the kingdom, have initiated and supported the legislative measure designed to secure the public health. Well and nobly have they fulfilled their mission! But it may be objected, that I am myself a medical man. Such undoubtedly is my high privilege. Let, then, other and, as it may be called, more disinterested witnesses speak. In the course of the preliminary inquiries prescribed by the Public Health Act, more than two hundred towns have been examined by the engineering inspectors of the General Board of Health. Those gentlemen have been brought into immediate contact with all classes and all callings; and knowing well their sentiments, I may, without entering into invidious personalities, say that the disinterested spirit displayed, and the all-important support rendered, by the whole body of our profession, has inspired them with esteem and admiration.

But let us return to the more immediate object before us—the question of sanitary improvement. In the course of this paper, several marked instances have been incidentally noticed, in which the removal of the assigned cause of sickness was followed by improved health; and equally striking evidence will be found in the excellent reports of my valued friend and colleague, Dr. Sutherland. If time permitted, I could adduce example upon example, proving equally on the largest and the smallest scale, that every really effectual improvement has been followed by a diminution or eradication of zymotic, and even of other diseases; for it could be abundantly shown, that the benefit is never restricted to the former class, though it is there more marked. A work-house has been drained, flagged, and ventilated; the health of the inmates has immediately improved, and they, though previously suffering from fever, diarrhoea, and so on, have thenceforward been greatly or entirely exempt from these diseases. A new and lofty ward, well ventilated, has been substituted for an old and close one, as at St. Thomas's and other hospitals. What has followed? The diminution of erysipelas—the hospital test of a foul atmosphere—so marked, as to have attracted the notice of the medical officers. A foul labyrinth of unpaved, wet, and filthy courts has been flagged, dried, and cleansed, as in a part of Newcastle-on-Tyne, called Sandgate; and there ensues so great and permanent a reduction, that it is capable of being reduced to figures, and expressed *per centum*, as in the case of St. Olave's, Southwark, and elsewhere. A large ship, ventilated by the skill of an Arnott, transports to the antipodes 1000 convicts, soldiers, and sailors, and only one old man dies on the passage; whilst an emigrant ship, unventilated and neglected, is decimated in crossing the Atlantic. Again, a lunatic asylum or a prison is properly and efficiently provided with sanitary arrangements, and in

the midst of a great and sweeping epidemic, like that of cholera in 1849, their inmates escape, one and all.

In some instances of this kind, it has lately been said that the new system has failed; and even that epidemics, from which the old establishment was free, have, as the consequence, sprung up in the new. I have had occasion to inquire officially into some of these alleged cases of failure, and it has been shown to the satisfaction of important public bodies, who had entertained the above opinion, that the occurrence of the sickness was traceable, not to the principles of sanitary improvement, but to defects in construction, or mistaken plans; nay, in some cases the very efficiency of one part of the arrangements has, owing to fundamental errors, exasperated the mischief. No one, for example, would deny that it is a great amelioration to substitute in a crowded court, or in the cellar of a house, a cleanly water-closet for a foul privy; but it does not therefore follow, that it would be equally desirable, if at all, to place a water-closet in the cell of a jail, within six feet of the head of the bed, and where the prisoner spends twenty-two out of the twenty-four hours. An efficient ventilating apparatus for public establishments, such as I have seen, is of vast importance if in right relation to all parts of the buildings; but if it is misplaced in regard to water-closets or drains, it may, as I have found, by the very force of suction which is its merit, poison the atmosphere, by drawing the foul air out of the soil-pipe or of the common sewer; and this notwithstanding the supposed defence of syphon or other water-traps. But besides these more obvious sources of failure, there are others more subtle and general, and, therefore, more important, which altogether escape the notice of those engaged professionally in sanitary works; for instance, every plumber and engineer ought to know thoroughly the great principle of the diffusion of gases, as it is immediately concerned with the efficient action of all water-traps.

In glancing at the results of sanitary improvements, it is interesting and important to consider the results that have followed the introduction of the *model lodging-houses*. These institutions afford a kind of evidence which is of special value, inasmuch as the great object of their philanthropic founders was to test the value of sanitary improvement; and further, because the information derived from them is exact, numerical, and trustworthy. It is probably known to the majority of this audience, that these houses are situated in all parts of the metropolis, and several of them in the centre of the most unhealthy districts, as St. Giles and Drury Lane, where every form of zymotic disease prevails, and from which fever is never absent. They are occupied by the labouring classes; and although, in some of those for families, the tenants belong to a superior class of artisans, in others, especially those for single men, persons following the humblest occupations, as itinerant sellers of articles in the streets, are lodged by the week.

The following details are taken from the official reports which I have had occasion to make on the subject:—

"In May 1851, I personally examined seven out of the eight existing establishments. The inhabitants (concerning whose health I instituted a searching inquiry) then amounted to 1,507, of whom 726 were children—a class most susceptible of zymotic disease. There had been only one case of typhus from the commencement; and yet one of the institutions, with 550 inmates, had been opened three years and a half. At the time of the cholera, the population of these houses amounted to 795; and yet there was only one case of cholera, whilst among the population of London generally, including all classes, one person in every 151 died, and about one in every 75 was attacked.

"The statistics of the Metropolitan Buildings, Old Pancras Road, are peculiarly instructive, inasmuch as they have been now open nearly five years, and contain a fixed population, of whom many are labourers and mechanics. Up to May 31, 1851, the yearly mortality had been less than more than two per cent. of the inmates, which is a

same as the average mortality of England.* I have lately again visited this establishment; and the results are even more remarkable; for during nineteen months, up to October 1852, with an average population of 640, there have been only thirteen deaths, being 1·2 per cent. per annum, or at the rate of only 12 in the thousand. In another establishment for families, in Albert Street, Spitalfields, with about 300 inhabitants, the mortality during the last eighteen months has been much lower than even that in the Pancras Road institution. The rate of mortality in England and Wales at present is 2·2 per cent., or 22 in the thousand; in the metropolis it is 2·39, or nearly 24 in the thousand; in Liverpool it is 3·43, or upwards of 34 in the thousand; while in the part of Surrey not included in the metropolis, it is 1·72, or 17 in the thousand.

"But properly to estimate these facts, it must be stated that the number of children, which, if considerable, always raises the mortality, in the Metropolitan Buildings considerably exceeds the proportion in London generally; in 1851, for example, they formed 62·3 per cent. of the total inmates; and yet the mortality among them was only 2·5 per cent.; whilst in the metropolis, in 1841, the number of children under ten years of age was 21·7 per cent. of the whole population, and the mortality was 5·2 per cent., or nearly double that of these model houses. The experience of the last nineteen months still shows the same exemption from fever as in the earlier years, not one death having occurred from that cause; nor was there any death from small-pox or scarlet fever. Two cases of small-pox occurred among the adults, both of which recovered; and it is interesting to observe that the disease did not spread, not a single child having been attacked. Whenever, on the contrary, a case of small-pox occurs in the crowded habitations of the poor, and especially in the common lodging-houses, it is notorious to medical officers that it spreads rapidly among the sickly and predisposed population around. I recently had occasion to inspect a court at Gloucester, containing twenty-two families, and about 110 individuals, and where in two months there had been thirteen cases and three deaths from small-pox."

This paper will, it is hoped, assist in placing in a clearer point of view two of the most general and influential agents which concur in lowering the health of the swarming population of our suburban districts. The proofs, too, derived from so many sources, demonstrating the possibility of destroying one of the two conditions on which the development of epidemic disease depends, will not, I trust, be unacceptable to those who are interested in that which, in regard to the physical well-being of the people, is the great question of the present times. And if we, who form a part of the more favoured classes of society, escape the miseries and sorrows of our humbler brethren, let us never forget that it is due rather to the fortuitous march of events than to any inherent superiority which we are entitled to claim as our own. The foul abode, the unwashed body, the reeking excrements by which thousands of our industrious countrymen are surrounded, inflicting a penalty from which the brute, in virtue of its instinct, is mercifully protected—these, and an untold number of the like afflictions, might, but for the goodness of God, have been our own lot; nay, worse, the fate of our wives and of our children. It might, but for the accident of birth, have been ours to see those nearest and dearest to us pining, sickening, and dying, before our eyes, the victims of a pestilential atmosphere, from which, though recognised, there was no escape; thus adding to the bitterness of death the consciousness that it was thus caused, and was no necessary part of the primeval curse. It might have been our fate to feel the very springs of life and energy giving way in the midst of manhood, and when a young and helpless family depended on the vigour and capacity for labour which constitute the poor man's only fortune. To those who are ignorant of the scenes daily en-

acted in the crowded and foul abodes of the populous districts of England, and even in the very centre of the metropolis, this language may bear the semblance of exaggerated sentimentality; but I have, by a long and painful experience, been taught that no words can express, no picture can realize, the misery to which large masses of the labouring population of this country are at the present moment subject, owing to the existence of evils which are doubtless in the main attributable to the unprecedented increase of our manufacturing towns, but which must in no inconsiderable degree be referred to that neglect, out of which, after a lapse of centuries, we are now beginning to awake.

Highgate, February 1853.

ON PYÆMIA.

By JOSEPH SAMPSON GAMGEE, Esq., House-Surgeon to University College Hospital.

(Read before the Medical Society of University College, Nov. 25th, 1852.)

A CONSCIOUSNESS of the vastness and intricacy of the subject on which I have undertaken to submit to you a few reflections, and a feeling of my own inability to do it justice, constrains me to appeal to your indulgence; an appeal, the special need of which will at once be perceived, when I confess that I do not intend this communication to be a mere compilation of the ideas of authors on the subject of Pyæmia. The great discrepancies between them render it obvious that they are not all right; and my own clinical observations in thirteen cases force me strongly to suspect, that in many very important points the great majority of them are far from the truth. Thus believing, I should deem it most just to myself, and most consistent with my duty, to relate the histories of my cases, to analyse them, and then to point out in what respects my own observations agree with, or differ from the teaching of the day. But to carry this plan into execution, copious as my notes of cases are, a series of addresses, and not a single one, would be required; and hence I am forced to abandon it for another more expedient, though to me less congenial, and I fear to others less efficient scheme. Under existing circumstances, I must confine myself to presenting a sketch of the present state of knowledge among surgeons, especially among English surgeons, on the subject of my thesis, and to giving a succinct account of the disease. In so doing, it shall be my special study to adduce from my note-book of cases as much evidence in support of my statements and of my criticism on accepted opinions, as time will permit.

Anxious as I am to be brief, I cannot abstain from making a few preliminary remarks.

Such is the present state and rate of progress of pathological science in general, but especially of surgical pathology, that even in the humblest of inquiring minds, a zealous desire to do somewhat to contribute to its advancement cannot but be awakened. If this be true in general, how true is it in this particular instance. Let any one look on a poor creature first seized with the pyæmic shiver: the violent shake of the whole body, the drawn and haggard features, the dim and sunken eye, the earthy look, the mental depression, the succeeding intense heat and profuse sweating, will at once indicate to him that something serious has happened. A succession of these attacks, the supervention of diarrhoea, and mental aberration, not unfrequently in a few hours hurl a previously stout and healthy man into eternity. Let the witness of this scene bear in mind that, but a very few years since, this disease was unknown; that there are very strong grounds for believing that it is among the most frequent of surgical diseases, and yields to none of them, if it do not exceed them all, in its fatality; that at the present day, to my certain knowledge, surgeons of eminence have shewn themselves ignorant of typical cases of this disease brought under their observation; that in the most recent systems of surgery, strong presumptive evidence

* Report on the present state of certain parts of the Metropolis, and on the Model Lodging Houses of London. By R. D. Grainger, Esq., p. 29.

is afforded in favour of the belief that their authors have exceedingly indefinite notions on the subject; that writers of monographs are not only remarkably at variance on some of the most important, nay, of the fundamental questions involved in the subject, but have for the most part studied it in a manner which, if pursued for ever, will fail to lay bare the naked truth; let these facts, I say, be borne in mind, and then I may hope to be judged fairly, when I state my intention to make this paper the commencement of a critical inquiry into the present state of knowledge of this disease, with the ulterior view of contributing something to its elucidation. In the criticisms which I have to make on the labours of others, it shall be my earnest endeavour to express myself in unobjectionable terms; but should I, in the opinion of any one, fail in doing so, I trust that my intentions will not be misconstrued, however much I may fail in their fulfilment.

By pyæmia, I mean an affection almost invariably fatal, characterised by the rapid formation of purulent collections in different parts of the body, usually occurring as a sequel of suppurating wounds, but sometimes of spontaneous origin. While making use of the term pyæmia, which signifies an admixture of blood and pus, I do not intend giving in my adhesion to any particular doctrine as to the nature of the disease: its synonyms "purulent diathesis", "purulent infection", "purulent resorption", "purulent metastasis", are, like it, liable to the objection of being the expressions of theoretical opinions, rather than names signifying the correct nature of the disease.

As already stated in the definition, the great characteristic of pyæmia is the formation of purulent collections in different parts of the body. As peculiar features of these collections, I would call attention, firstly, to the great rapidity with which they frequently form, three or four days alone sometimes sufficing for the development of numerous abscesses in the lungs, and the collection of immense quantities of puriform fluid in the muscles and in the serous and synovial cavities. Secondly, to the asthenic character of the accompanying inflammation. In exemplification of this character, I may state, that I have met with considerable purulent collections in the pleura, and in some joints, without having been led to suspect their existence by any complaint of the patient. Thirdly, to the very general distribution of purulent deposits over the body. Though no tissue is, I believe, exempt from them, doubtless it is that they are more frequent in some parts than in others. The lungs are their seat of predilection; next in order I should place the serous and synovial cavities; then the muscles, the liver, and other organs. I have in three cases met with metastatic abscesses in the prostate, a part in which no mention of their occurrence is made by the best writers. The fact that I have found them there so frequently, comparatively to the small extent of my experience, taken in conjunction with the fact that the prostate often escapes unexamined at autopsies, induces me to think it probable that abscesses of the prostate in pyæmia may be more frequent than authors have hitherto supposed.

As it is in the lungs that these purulent deposits are most frequently formed, it is necessary for me to dwell a little more at length on the characters which they present in these organs. They usually occur posteriorly and towards the lower part of the lung; but I have met with a metastatic abscess at the anterior edge and at the extreme apex, though the remainder of the upper lobe was perfectly healthy. Another very general character is, that the surface, rather than the deep part of the organ, is their seat of preference. On the surfaces corresponding to the interlobular fissures, and on the diaphragmatic surface, they are about as frequent as on the exterior.

They vary in size from a pin's head to a walnut, and present themselves under two different aspects: (a) As circumscribed collections of apparently laudable pus. (b) As solid yellowish masses due to infiltration of the lung substance with pus, as proved in many cases by this fluid exuding from them on pressure. Frequently the lung substance for

about half an inch around is of deep red colour, non-crepitant and sinks in water: in many cases again, it is only at a small part of the confines of the abscess that the red hepatization exists; and the lung tissue is not unfrequently found crepitant and otherwise healthy in the immediate neighbourhood of one of these puriform deposits.

As to abscesses in the muscles, it has been stated by Nélaton* that they are comparatively rare; and that, when they exist, the muscular fibres are sharply cut around the pus-containing cavity, which appears to be the result of the softening down into pus of the fibres amid which it exists. With reference to the first part of this paragraph, I am disposed to doubt its accuracy, and to regard the muscles as a rather favourite seat of these deposits; but possibly the frequency with which I have found them there is the result of accident in my brief experience: certain it is, however, that the pus is not always collected in circumscribed cavities, for it is sometimes diffused pretty uniformly between the interfascicular cellular tissue, without the least tendency to circumscription, much less to the formation of a cavity.

It may have been observed, that I have frequently made use of the term puriform fluid, instead of pus; and as my doing so has not been the result of caprice, it is necessary that I should state my reason. It was in the summer of 1851, that I first heard of the purulent depositions in pyæmia being destitute of true pus-corpuscles, and abounding in granular corpuscles, in which no such thing as the characteristic nucleus of the pus-cell was to be seen. This was made known to me by my friend Mr. Joseph Lister, as the result of his observations in one of the cases on which he wrote for the Fellows' Clinical Prize, in the summer of last year. I have since discovered that similar observations had been made by others; and I have observed the same fact myself. To convince you of its importance, I need only tell you, that on the character and size of the pus-corpuscles, a theory as to the mode of formation of the abscesses in pyæmia has been formed, and it will at once be perceived that the discovery of cases of this disease with corpuscles, other than those of pus, is a serious invalidation of the basis of such theoretical teaching.

In stating that the great anatomical character of pyæmia is the formation of purulent collections in different parts of the body, it may appear that I have given but a partial statement of the anatomical essence of this disease, in having omitted mention of the state of the blood. I have done so, because it appears to me that the consideration of this point may for the moment be profitably deferred.

SYMPTOMS. Though necessarily incomplete, this pathological sketch will serve as a preparation for the more ready appreciation of the value of the symptoms.

A patient with a suppurating surface, doing well in every respect, is seized with a fit of shivering, which passes off in about a quarter of an hour, and is succeeded by more or less intense heat. Gradually the bodily temperature falls to its normal standard, and the patient is perhaps left in as good a condition as he was in prior to the rigor. But a few hours, rarely two or three days, elapse before a similar rigor and succeeding heat are manifested; and then, if not at the first, is the patient's appearance markedly changed—the eyes are sunken, and the features drawn.

Quite suddenly, notable emaciation appears to have occurred; and ere long, the skin and conjunctivæ acquire a more or less icteric tinge. In rarer cases, the face becomes of leaden hue, the respiratory and cardiac movements are much accelerated, the breath has a peculiar odour, the wound presents an unhealthy appearance, the tongue dries, sordes accumulate on the teeth, symptoms of pleurisy and of articular affections may supervene, and abscesses form in different parts of the body. As the bodily weakness increases, the mental faculties become impaired, and life ends.

This narrative of symptoms may be quite applicable to a particular case, though I have compounded it from a

* *Eléments de Pathologie Chirurgicale*, t. Ier, p. 382.

number of histories, and intended it as a general outline, rather than as a detailed account. It is now time to examine more particularly into the diagnostic value of some of the most prominent semeiological characters to which I have called attention.

I. *The Shivers.* Occurring, as this sign does, in a variety of affections, it might *a priori* be regarded as of little aid in diagnosis. The reverse is the case; yet its importance must not be exaggerated. It is usually severe, and associated with remarkable depression of spirits and alteration of countenance. It rarely exceeds a quarter of an hour in duration, and usually occurs at periods varying from twelve to thirty-six hours. In two cases, the patients have informed me that the violent shaking of the body has been unassociated with a feeling of cold. In some cases, the shiver is a symptom of very little value. I have seen a case of compound fracture of the leg, in which, on cadaveric inspection, metastatic abscesses were found in the lung. During its whole progress, the patient only shivered once, and then but slightly. Again, the shivers may merely be the forerunners of an attack of erysipelas; and it is only by the coexistence or absence of other signs that the diagnosis can be established.

II. *Odour of Breath.* The merit is usually attributed to Bérard of having first called attention to a peculiar odour as emanating from pyæmic subjects. The best idea I can give of this smell of the breath, is by comparing it to the smell of sweetish liver; so peculiar is it, that its value in diagnosis is very considerable. In one well marked case of the disease, which recently came under my notice, the breath had not, at any stage, the peculiar odour in question. On the other hand, it existed markedly in a man affected with prostatic abscess; and in another who died from extravasation of urine, after the operation of lithotomy: in both of whom I failed to discover, after death, the signs of purulent infection. These facts, it must be admitted, notably decrease the value of the breath's peculiar odour in diagnosis; still it is certainly of much worth in many cases. Its precise import will only be susceptible of determination when pyæmia shall have been clinically studied as it ought to be.

III. *Appearance of the Wound.* As a rule, the appearance of the constitutional symptoms of the purulent affection is attended with a marked deterioration in the appearance of the wound. If partial union have occurred, the bond breaks down, and the previously pink, compact, and pus-secreting granulations become pale and flabby, and pour out a thin, scanty, and offensive discharge. At other times the wound looks pale, and does not pour out any secretion; at others, again, it acquires a black colour as it dries. The neighbouring integument may be of perfectly healthy colour, or the seat of a faint blush; and when suppurative phlebitis is the cause of the affection, its signs are manifest in the neighbouring veins. Sometimes, however, the appearance of the wound very sensibly improves after pyæmia has set in; but the improvement is not durable. I have seen two cases of this kind.

IV. *Pulse and Respiration Ratio.* The number of the heart's beats, and of the respiratory movements, is, we have observed, much increased in this affection. How far the ratio is altered, known facts do not enable us to state; though their scantiness, conjoined with the fact that stethoscopic examination is, as a rule, difficult in these cases (the cause of this difficulty being the extreme restlessness of the patients), suggests the importance of further inquiry, as a means of determining the occurrence of chest mischief.

V. *Colour of the Skin.* In the greater number of cases, the skin at an early stage acquires an icteric tinge, which is also noted in the conjunctivæ. That this peculiarity of colour is not owing to organic disease of the liver, is proved by the fact that, in all the cases which I have seen, this organ happens to have been healthy. Of the leaden hue which sometimes occurs in this disease, one well marked instance has fallen under my notice. It occurs at an advanced stage, and is doubtless due to imperfect arte-

rialization of the blood, in consequence of extensive chest mischief. This existed in my case.

CAUSES. I have stated in the definition, that pyæmia is a disease usually occurring as the result of wounds, but sometimes of spontaneous origin. In stating that the disease may sometimes originate spontaneously, I am advocating a doctrine which has few supporters, but which, nevertheless, I believe to be correct. I have seen two cases of the kind; and as perhaps this is one of the most important questions which we shall have to discuss, I shall read the history of one of them, and state the reasons for my regarding it as an instance of purulent infection occurring independently of a wound.

CASE. Thomas Harley, of lymphatic temperament, aged 20, single, a French polisher, native of London, was admitted into University College Hospital, 30th October, 1852. He had never heard of consumption, cancer, or gout in any of his family, but his father was subject to rheumatism for several years before death, the cause of which was unknown. He had been a very healthy person, and had never laid up for illness. He was of very temperate habits; slept in an airy and dry back room; his working-place was warm and dry; he had never had rheumatism, scarlet or typhoid fever.

History of present Illness. About four months ago, the glands in the left submaxillary space enlarged, and continued so ever since. He continued in good health up to Sunday, 24th October, when the left side of the face began to swell, and he felt difficulty in swallowing. The swelling was painful, and increased in size up to Tuesday, 26th October, since when it had diminished, and been painless. The difficulty of swallowing disappeared on the 29th. On the evening of the first day of attack, he had a severe shivering fit for a quarter of an hour, after which he became very hot. He shivered every evening afterwards. He had been very thirsty. The bowels were open five times on October 29th, after medicine. On the day before admission, for the first time, he felt pain in the muscles of the calves and thighs, which continued in these parts ever since. He had also pain in the muscles of the body generally, and in the left knee and ankle-joints. For several days, even when lying still, he had had severe pain in the back of the head.

Present State. Three o'clock, p.m., 30th October. The pulse was 112, of pretty good size, but weak and soft; the respirations 36; the skin hot and dry. He had very severe pain at the back of the head when he moved it, not otherwise, and a good deal of pain in the eyelids; none in the eyeballs. The face was pale, except over the swelling on the left side, where the skin was red. There were slight sordes, both on the upper and lower teeth; the tongue was moist all over, vividly red at the edges and tip, and covered with pasty brown fur over the remainder of its surface; the papillæ at the tip were very prominent; the lips were dry, the lower one brownish. The breath was not peculiar. He had no cough, nor pain in breathing. There was a good deal of tenderness at the epigastrium (he vomited on the previous morning), not in other part of abdomen. There was no gurgling in the right iliac fossa; nor spots on anterior surface of abdomen or chest.

Limbs. There was pain in the left biceps muscle, but none in any other part of the left arm; also in the muscles of the right arm and forearm, increased by pressure; there was no pain in the joints of these limbs, nor in the muscles of the back, but the spine was tender from the middle of the dorsal region downwards. Great tenderness was manifested on grasping the muscles of the thighs, especially the right one; there was still greater pain in the calf, and some, but less, in the muscles in the front of the leg and on the insteps; but none in the joints of the lower limbs. Some tenderness was however felt on pressing over the inner malleolus. No redness or swelling was noticed in any of these painful parts. There was not, nor had there been, any wound in any part of the body.

Swelling of Face and Neck. On the left side of the face and upper part of the neck, was a considerable swelling, over which the skin was red and hot. The limits of this swelling were

not defined; it extended upwards to the cheek, backwards to the anterior border of the sterno-mastoid muscle, forwards almost to the chin, and downwards to the level of the upper border of the thyroid cartilage. Nothing was seen of this swelling inside the mouth. The lower jaw felt healthy, and the mouth was opened without pain, though with a little mechanical impediment, owing to the size of the swelling, which felt hard everywhere, except at the anterior and lower part, where very distinct fluctuation was felt. On making an incision in this situation, exit was given to about a drachm of pus mixed with blood. A little lint was introduced into the lips of the wound, and hot linseed poultice applied all over the swelling, to be renewed every six hours.

11, P.M. He had had two copious stools, after a dose of castor oil. On removing the poultice and lint from the aperture, and on pressing in the neighbourhood, a good deal of laudable pus escaped. The swelling, heat, redness, and pain were much diminished.

October 31st, 10 P.M. Pulse 120, full, and rather bounding. Respirations 28. The skin was hot and dry; the tongue brown in the centre, but less so than yesterday: the tip and edges were vividly red. He had no motion this day. He felt very weak, and complained of great pains in the loins, and also in the joints and muscles of the limbs. The abscesses discharged perfectly laudable pus, in small quantity. The left biceps was much swollen, and the skin covering it was hot and red. The muscles on the back of the right forearm were in precisely the same condition. At the under part, and almost at the middle of the right thigh, was a diffused swelling, about the size of a fist. It was hot and very tender, and the skin over it was reddish. In front of the left ankle, the skin was red; and the redness extended about half way up the front of the leg; without, however, any swelling. There was no pain in the course of the large veins; he had great thirst; no peculiar odour of breath; no cough. Hot fomentations were ordered to be applied to the swollen parts.

November 1st, 10, A.M. The swelling in the parts of the limbs mentioned in last report, was on the increase. Pulse 128, tolerably full, soft. Respirations 36. The respiratory murmur was perfectly healthy all over the front of the chest. The patient was in such pain, that the back could not be examined.

Midnight. The skin was hot and moist; but the patient said that he felt cold. He was evidently somewhat light-headed. The nurse informed me that, for the last two days, he had talked incoherently in his sleep. He had no peculiar odour of breath: the tongue was moist, dirty white furred, but much less so than at admission: the pupils were much dilated, and fixed.

November 2nd, 11 A.M. The pulse was 150, of medium fulness, soft; the skin hot, and bedewed with perspiration; the pupils extremely dilated, and slightly, but very slightly moveable, when a lighted candle was approached to the eyes; the face much drawn; the expression wild and haggard. He was extremely restless, and constantly chattered incoherently and somewhat indistinctly, about a great variety of matters. The bowels had not been opened since yesterday. There was no discharge from the abscess on the left side of the face. The redness in front of the left ankle was not so great as it had been; but the redness in front of left leg was greater than yesterday, and was now associated with heat and swelling. The signs of phlegmon under the right thigh had diminished; those in the right forearm and left biceps remained the same. There were now also redness, heat, and swelling, on the back of the left forearm. About the centre of the wrist of the right forearm, I this morning had felt apparently distinct fluctuation; but no matter escaped on a puncture, half an inch deep, being made with a narrow bistoury. There was no peculiarity in the odour of the breath.

A drop of blood taken from the back of the right hand and tip of the right index finger (both parts apparently healthy), showed a very large excess of white corpuscles on the addition of acetic acid. I asked Dr. Jenner to examine this blood,

before I told him of the case. He kindly did so, and said that there was a large excess of white corpuscles; and, in answer to my question as to whether there were any pus-corpuscles, replied in the negative. I had already made up my mind to the same effect. The white corpuscles in no way differed in character from those of healthy persons: the great majority of their nuclei were of a horse-shoe shape; others were centrally grouped, but their divisions were separated from each other, and not aggregated into a central mass, as the nuclei of pus-corpuscles.

4, P.M. There was no sensible change since the last report, except that a good deal of perfectly white foam escaped from the mouth, and that the powers of speech had become much impaired.

7½, P.M. The nurse informed me, a few minutes before this time, that the man had just died. Her account agreed with that of several gentlemen who witnessed the case, to the effect that the face had acquired a decidedly purplish or bluish tint shortly before death.

Examination of the body, at 9, A.M., Nov. 4th. Cadaveric rigidity was generally well marked, as was also the livid discolouration of the posterior surface of the body. This livid discolouration did not advance uniformly on the sides of the trunk; but those parts, as well as the neck, clavicular regions, and arms, were mottled livid. The left arm was less mottled than the right; and whereas the skin was perfect on the latter, the cuticle was readily detached in large shreds from the inner aspect of the former, which, moreover, was somewhat, but not much, larger than its fellow. The right forearm was somewhat larger than the left: both were evidently rather larger than natural. They pitted slightly on pressure. Their palmar aspect was livid (both had been in a prone position). The dorsal aspect of the right arm was of a yellowish white colour; that of the left was slightly mottled. The external surface of the left leg was decidedly somewhat larger and paler than the right. On looking at, and manipulating the posterior aspect of the thighs, no perceptible difference was found. Nothing peculiar was noticed on looking at and manipulating the joints.

Thorax. On removing the sternum, the parts appeared perfectly healthy at the first view. There was no fluid in either pleura; no adhesions on the left side; but some firm old ones on the right. Some blood, very carefully collected from a puncture made in the superior vena cava, which had been previously dissected out, showed, when acted on by acetic acid, the white corpuscles in excess, but by no means so much so as they appeared in the blood examined during life. Among the white corpuscles, I saw some with nuclei which I could not distinguish from the nuclei of pus, and which were certainly different from those which I saw in this man's blood during life. Dr. Jenner also acknowledged the similarity, but did not believe that the suspicious looking nuclei were those of pus-globules. My friend Mr. Lister happened to call on me while I had this blood in the field of the microscope. Without giving him any reason to suspect the nature of the case I was inquiring into, I asked him to give me his opinion as to what was in the field. He at once exclaimed, "Oh, you have pus here!" When I pressed him for his reasons, he said some of the nuclei were characteristically pus-like; but he did not feel much confidence in the stated distinctions between pus and white blood-corpuscles. He added, however, that he had never before seen blood with corpuscles like those under the microscope.

Left Lung. There was no sign whatever of metastatic abscess in any stage. It was everywhere crepitant. On section, some blood-aerated liquid exuded. The infiltration of this fluid affected all the lower part of the lung, from the base to the apex. There were no tubercles, nor emphysema. Portions of this lung floated, even after extreme pressure. The congested portion readily broke down on pressure.

Right Lung. The preceding description applies strictly to it. On the diaphragmatic surfaces of both lungs, especially of the right one, were numerous little dusky spots; others, of slate colour, being deeper seated.

spots simulated those met with in scarlet fever, and other blood-diseases. The lung-tissue immediately beneath these spots did not materially differ from the lung in any other part.

The heart, liver, kidneys, and prostate gland, were healthy.

The spleen measured six by three and a half inches. It readily broke down on pressure, but otherwise appeared healthy.

Brain. On removing the dura mater, the brain appeared generally pinkish; very notably more so than in health. On examination, the pink colour was found to be due to a large number of minute capillaries, which were quite as numerous on the anterior as on the posterior part of the brain. The superficial veins were not preternaturally congested. On section, the brain-substance appeared remarkably healthy. The *puncta vasculosa* were, however, more marked than natural; drops of blood, of considerable size, exuded from many of them. There was no excess of serum in the lateral ventricles; nor congestion at the base of the brain, which, in this particular, differed remarkably from the upper surface. The cerebellum presented nothing remarkable.

Abscess of Neck. On removing the integuments and platysma from over the seat of the first abscess, on the left side of the upper part of the neck, its cavity was found irregular, extending backwards under the parotid, forward under the submaxillary gland, and downwards for a little distance, and beneath the sterno-mastoid. The neighbouring muscles were healthy on section. The cavity contained about 3ss. of apparently good pus, which, on microscopic examination, showed (with the aid of acetic acid) numerous pus-corpuscles with the characteristic nuclei.

Limbs. On removing the integument from the back of the right forearm, the subcutaneous cellular tissue was found infiltrated with liquid not unlike melted butter. On dissecting the part, the intermuscular cellular tissue, especially in the superficial and deep layers, was loaded with the same liquid, which, in parts, was opaque, and similar to pus, to the naked eye. Under the microscope, a small number only of pus-corpuscles, but granular corpuscles in very great numbers, were seen. A vein, coursing amidst the cellular tissue thus infiltrated, had transparent coats, and in every respect appeared healthy. On removing the skin from the left arm, an appearance exactly similar to the other was presented; but, on dissection, a notable difference between these two parts was discovered; for, whereas the muscles of the right forearm appeared healthy, the left biceps was infiltrated throughout its whole substance with purulent looking fluid, which was not collected in masses, but disposed in longitudinal strata, evidently in the interfascicular cellular tissue. This condition affected the whole arm, but did not reach into the axilla. On cutting into the left ankle-joint, it was found perfectly healthy.

As the dissection of the body had already proceeded to a considerable extent, the other joints could not be consistently opened; but, as already observed, there was no external sign of disease in any of them.

My reasons for regarding this as a case of pyæmia, after my first examination of the patient, were, that though some of the symptoms might be mistaken for an attack of typhoid fever or rheumatism, yet all their signs were not present, while others (those connected with the abscess) pointed to a different diagnosis. Admitting that all the signs of pyæmia were not present, and especially that it could be traced to no cause, yet the symptoms simulated it more closely than any other affection. The formation of the abscess contemporaneously with the commencement and progress of the constitutional affection, the subsequent manifestation of articular and muscular pains, and the aggravation of the general symptoms, while the signs attendant upon the formation of the abscess decreased, decided me in the diagnosis, in the correctness of which, cadaveric inspection confirmed me. True it is, that no abscesses were found in the parenchymatous organs; but they are not constant even in cases of traumatic pyæmia. I have, however, seen an instance of the idiopathic affection,

in origin, symptoms, and progress, precisely like Harley's; in which, however, the lungs were the seat of metastatic abscesses. If it be admitted that Thomas Harley was the subject of pyæmia, there can be no doubt that the affection was independent of injury.

Certain it is, however, that in by far the majority of cases, pyæmia occurs as the result of injury. It is met with after slight, as well as after severe, wounds; after injuries to the soft parts, as well as to the bones. It is said to be especially liable to occur as the result of wounds of veins. In reflecting on this point of my subject, an important question has presented itself to me for solution. Continental writers dwell incomparably at greater length in their descriptions of this disease, than do our own. In visiting English and foreign schools, I have been struck with the fact that, whereas little mention was made of pyæmia in the former, it was regarded as a frequent complication of surgical practice in the latter. These facts suggest the question, Is the disease more frequent on the continent than in England? The momentous import of this question can scarcely be exaggerated.

The mode of dressing wounds, and the low dietary scale, prevailing in continental hospitals, tending as they do to deteriorate the quality of the secretion of pus, to favour its accumulation, and to lower the powers of the system, might be regarded as fruitful causes of the purulent infection; and so they have been by Professor Sédillot.* Of nine cases of this disease which I carefully studied in the Florence Hospital, one occurred as a sequel of venesection; two after compound fracture of the leg; one after punctured fracture of the skull; two after amputation of the thigh; one after necrosis of the jaw; one after extirpation of a tumour in the breast; and a ninth as a sequel of opening a small abscess in the groin.

As a whole, these are not cases in which continental differs most widely from English practice; and hence my own observation would not be favourable to the doctrine, that such difference leads to a greater frequency of the purulent infection in the hospitals of continental Europe, than in our own. To the fact that much less space is devoted to the consideration of this disease in the works of our own, than in those of foreign surgeons, I am disposed to attribute little value, as an evidence of the comparative rarity of this disease amongst us. On the contrary, the very great scantiness and ambiguous tone of the writings of English surgeons on pyæmia, taken in connexion with the errors of diagnosis which I have witnessed, and with the confession made to me by a candid and eminent teacher in this metropolis, that, to his certain knowledge, no definite value was attached to the symptoms of the disease a few years since,—forces me to suspect that the greater frequency of this affection on the continent is less real than apparent.

The settlement of this question by extensive observation is much to be desired; for, if the reply be in the affirmative, the question will arise, What is the cause of the greater frequency? The solution of this problem may reasonably be expected to give a clue to the real cause of the disease, and consequently to the means of preventing it. On the contrary, if it shall appear, that in our own, as well as in continental practice, pyæmia rages with equal virulence, the theoretical notions now entertained as to the influence of peculiar dressings, etc., will be swept away, and the propriety will be apparent of diverting the channel of research for the discovery of the etiology of pyæmia.

It may already have been gleaned from remarks incidentally made, that, when once pyæmia has been diagnosed, the prognosis must be unfavourable. Nélaton† states that the disease is invariably fatal; but I am inclined to believe that such is not strictly the case. The grounds of my belief are histories of cases related by Sédillot‡ and Vidal§, and of others contained in my own note-books. Nevertheless, the great fatality is an undeniable fact.

§ Traité de Pathologie Ext., etc., 3me. Edit. Tome deuxième, p. 27.

Briefly as I have been obliged to treat my subject, I would gladly make amends for the defect by dwelling at greater length on the all-important question of *treatment*. If, by so doing, I had it in my power to contribute facts worthy of knowledge, I might be disposed to transgress the duty I have been obliged to impose on myself, of being brief; but, since entering into a discussion of the numerous modes of treatment proposed would demand time out of proportion to the instruction it would afford, I deem it advisable to proceed to analyse the opinions held by authors as to the nature of the disease.

These opinions may be arranged under two heads: firstly, those which hold pyæmia to be an aggravated form of inflammation of the veins; secondly, those which hold it to be a distinct disease.

The discovery of the symptoms, anatomical characters, and consequences of phlebitis, was one of the many fruits of the labours of John Hunter. He saw cases of death with the formation of metastatic abscesses after suppurative phlebitis, of which he regarded them as an aggravated form. In 1828, a paper, under the title of a "Pathological Inquiry into the Secondary Effects of Inflammation of the Veins", was read before the Medico-Chirurgical Society, by Mr. James Arnott, who has ever since been regarded by English surgeons as the prover of the doctrine, that the occurrence of purulent deposits and death, after surgical operations and injuries, is due to inflammation of the veins. This doctrine is taught, with but slight modifications, in the writings of Samuel Cooper, Liston, Syme, Hyde Salter, Bransby Cooper, and Vidal.

It is but just to say that, of this number, Vidal is the one who has given by far the most complete account of the disease. I have said that these writers have reproduced the teaching of Mr. Arnott, with but slight modifications: to one of the most notable of these I wish to call attention.

In his "Elements of Surgery", Mr. Liston remarks, that "when, from any cause, the extremity of a large vein in a wound is not closed, when it is not plugged up by plastic matter, pus seems to enter it readily, and, by mixing with the circulating fluid, causes dreadful mischief. Great constitutional disturbance accompanies the purulent deposits which follow in the solid viscera, and in the joints. Inflammation of a vein is also occasionally followed by the sudden appearance of a purulent deposit in some part of the body, external or internal, at a distance from the inflamed part."

Thus, though Mr. Liston shewed his leaning to the doctrine of Hunter and of Arnott, by alluding to the disease in his chapter on Inflammation of the Veins, he partly dissented from it, by acknowledging the possibility of a disease, similar to the alarming constitutional complication of suppurative phlebitis, arising from the entrance of pus into the circulation through an opening in a vein.

While there can be no doubt that suppurative phlebitis is about the most frequent cause of pyæmia, it is equally true that it is not the only cause; and that to regard pyæmia as suppurative phlebitis, is to mistake the effect for the cause. Even without taking into account those undoubted cases of spontaneous pyæmia, which are unassociated with disease of veins, certain it is that, in not a few cases of the disease following injuries, no trace of venous inflammation has been discovered. I have failed in discovering it in cases in which I have most accurately dissected the venous system; and even Bérard admits the existence of such cases; though he, a strong believer in the phlebotic doctrine, keenly perceiving what formidable obstacles to the safety of his theory such cases would be, endeavours to explain them away, by saying that the inflammation may have affected some venous radicles which have escaped detection.

But such a mode of argumentation, vicious as it is as a *petitio quæstionis*, cannot be assented to. If there are cases, as there undoubtedly are, even according to the admission of Bérard himself, in which the most careful dissection, purposely conducted, fails to discover the slightest trace of inflammation of the veins, the only legitimate deduction

is, that pyæmia may occur independently of, and, *ergo*, is not identical with, suppurative phlebitis.

We now come to the consideration of the doctrines according to which pyæmia is held to be a distinct disease. As the very antithesis of the doctrine propounded by Hunter and Arnott, Bérard and Vidal, I must first call attention to the opinion promulgated by Tessier in 1838, to the effect that not only is pyæmia a distinct affection, depending upon a blood-disease, but that it is always independent of venous suppurative inflammation. He grounded his opinion on a dogma which he thus expounded: "At all stages of venous inflammation, the pus is enclosed in the cavity of the vein by clots or false membranes, and at no period of the anatomico-pathological existence of phlebitis is its entrance into the blood possible."

Tessier, in thus expressing himself, erred, though in a different direction, yet for a similar reason, to that which led his opponents into error. On both sides, partial observation, and too sweeping generalization, were the screens which hid the truth. Certain it is, as has been long known, that cases of suppurative phlebitis do occur, in which neither clot, nor any other obstruction, exists between the pus accumulated in the inflamed veins and the heart; and in which, consequently, there is nothing to impede the admixture of pus with the circulating vital fluid.

Opinions differing from all those I have hitherto recorded have been published by Nélaton, Fergusson, Miller, Chelius, Lee, and Sédillot; and it is on these that I must now make a few remarks.

Nélaton recognises phlebitis as a powerful cause of this disease, though he avows himself ignorant of its mode of operation, and expresses a belief that pyæmia probably occurs spontaneously in some cases. In thus holding an opinion intermediate between that of Hunter and his followers on the one hand, and of Tessier's school on the other, Nélaton has, I believe, approached nearer the truth than any other writer.

Fergusson, Miller, and Chelius, have briefly alluded to the disease in question, as one due to purulent absorption; but so brief and indefinite are their statements, that their writings must rather be held as proofs of the comparatively little importance which they attach to the subject, than as evidence of their adhesion to any particular doctrine.

Mr. Lee's opinion may, to some extent, be gleaned from the following passage at page 45 of his very elaborate monograph *On the Origin of Inflammation of the Veins, and on the Causes, Consequences, and Treatment of Purulent Deposits*:—"The introduction of pus into the system through an injured or inflamed vein, can rarely be the first step towards purulent infection of the system. Some change must previously have passed in the blood, by which its coagulating power is impaired, or some unusual mechanical means must have been employed, before the pus can find its way in the course of the circulation."

The main ground of Mr. Lee's opinion is experiment; and we must test its validity, as well as that of his mode of arguing thereon, in order to ascertain the purport of his teaching.

In the preface to his thesis, the following passage occurs:—"The simple experiment of mixing some pus with healthy recently drawn blood, will at once show that such a combination cannot circulate in the living body. It will be found that the blood coagulates round the globules of pus, and forms a solid mass, which will adhere to the first surface with which it comes in contact; and it will be evident that it is not till the coagulum formed is broken up or dissolved, that its elements can circulate with the blood."

To argue, as Mr. Lee does, from the fact that, out of the body, blood coagulates round pus, therefore such a combination cannot circulate in the living body, is about as warrantable as it would be to predicate, from the observation that pure blood coagulates in a basin, it therefore cannot remain fluid in the ventricles of the heart. The fact is, that the circumstances are so materially different—blood in an earthen vessel on the one hand, blood in the living body on the other.

the other—that no inference deduced in the one case is applicable to the other.*

Mr. Lee's experiments on living animals, according to his own statement, tend to show that pus, by its tendency to coagulate the blood when introduced into the vessels, is arrested in its progress in some parts of the circulating system, and thus to afford valid evidence in support of his opinion. But the soundness of Mr. Lee's observations may fairly be questioned. Moreover, Sédillot never found any difficulty in injecting pus into the circulation, and he thereby repeatedly produced a disease identical in symptoms and anatomical characters with the pyæmia met with in surgical wards; and I have been informed by a friend—a very trustworthy experimenter—that in trials which he conducted, Mr. Lee's opinion as to the pus being incapable of circulating with the blood in the living body on account of producing its coagulation, proved to be erroneous.

In cases, says Mr. Lee, where, from long-continued disease, and the repeated introduction of vitiated fluids into the circulation, the blood has lost its power, there appears no reason to doubt the correctness of Dr. Sédillot's observations, that it is probable that pus-globules may then circulate with those of the blood. Now, Sédillot's observations, to which Mr. Lee here makes allusion, are observations of fact; and the only mode in which they can be refuted, is by other experimental observations which shall, if not point out the truth, at least lay bare the fallacy, if any, of the French surgeon's observations. On a matter of such vital importance to the existence of his doctrine, it would have been well if Mr. Lee, instead of satisfying himself with saying that, under such and such circumstances, *there appears no reason to doubt* that pus-globules may circulate with those of the blood, had had recourse to experience, examined specimens of blood, and then analysed the conditions of the patients from which they were obtained. To say, apart from such experience, in support of a doctrine, that the circulation of pus in the blood is prevented by the power of the former to induce coagulation; to say, I repeat, apart from such experience, in support of such a doctrine, that there appears no reason to doubt the possibility of pus circulating with the blood when it has lost this power, is begging the whole question.

If this criticism on the fundamental propositions of Mr. Lee's essay be just (and I believe it is), it must be admitted that the very foundations of his doctrine are assumed, and consequently, that it cannot be accepted as the theoretical explanation of the phenomena of the disease. The importance of refuting it will be at once evident, when it is borne in mind how baneful an influence incorrect theories always exert on the progressive study of the natural history of a disease, and, *a fortiori*, in the discovery of the best mode of treating it; a discovery which is almost hopelessly distant in pyæmia, and which will certainly only be arrived at by a just appreciation of the causes, signs, and anatomical characters of the disease, and by therapeutic experiments, conducted independently of any fallacious theoretical bias.

The only author to whose opinion it is left for me to allude, is Sédillot: whose work on the subject, published in 1849, must ever be regarded as one of the most valuable contributions to surgical pathology. He believes that the introduction of pus into the blood is the true cause of the phenomenon described under the name purulent infection, and the grounds of his belief are threefold.

First. A suppuration developed on some part of the economy always precedes the appearance of pyæmia.

Second. A manifest relation exists between suppuration of the veins and pyæmia. In this paragraph he merely states what cannot be denied, that pyæmia does sometimes follow suppurative phlebitis.

Third. The introduction of pus into the blood, and its presence there, admit of positive demonstration.

To the first proof I cannot give assent. The case of

Harley, which I have related, appears to give satisfactory evidence that pyæmia may occur without wound, but a still more exemplary case to prove the occurrence of idiopathic pyæmia has fallen under my notice; more exemplary, I say, because in addition to the disease occurring without that apparent cause, cadaveric inspection proved the existence of metastatic abscesses in the lungs. Such cases as these likewise invalidate Sédillot's statement, that the introduction of the pus into the blood admits of positive demonstration. But this statement is even opposed to experience. Cases of traumatic pyæmia do occur, in which all the veins capable of dissection are found to be closed at the surface of the suppurating wound, which has given rise to the disease. Even Sédillot admits the existence of such cases; and as they threaten the subversion of his doctrine, he endeavours to explain them away, by remarking that very probably venous erosions have occurred, too small to be seen, but large enough to admit the introduction of pus: but these erosions, he adds, could not occur without phlebitis, and then the pyæmia would have for double source the pus of the pyogenic surfaces, and that of the eroded venules. But what shall we say of this mode of argumentation on the part of one, who has made use of the fact that phlebitis is not always discovered after death in pyæmic subjects, to prove that suppurative phlebitis is not the sole cause of pyæmia; and who has condemned, as inadmissible, Bérard's explanation of the cases in which no phlebitis is found, that the inflammation may have been seated in the venous radicles, which, from their smallness, escaped detection?

As I have argued that, if by careful dissection no inflammation can be discovered, the only warrantable conclusion is, that none exists; so I must argue that if all the veins capable of dissection are found closed, it is not warrantable to assume the existence of openings apart from empirical observation. The presumptive evidence is in favour of the belief that cases of pyæmia occur without any solution of continuity, or other diseased condition of the veins.

The fact is, that if Bérard's mode of arguing be objectionable, Sédillot's is doubly so; for, whereas the former only assumes the possibility of phlebitis existing without being capable of detection, the latter assumes the existence of phlebitis, and openings in veins, without the means of proving either.

There is yet one opinion of Sédillot's to which I have to call attention. He states that the presence of pus in blood admits of positive demonstration by the aid of the microscope. The distinction between the corpuscles of pus, and the white ones of the blood, has always been held to be matter of serious difficulty: and a majority of respectable authorities have held it to be impossible to discover the existence of pus in the blood of animals into whose vessels it has been injected just prior to death. Sédillot, on the contrary, speaks of the discovery of pus in the blood of pyæmic subjects as an easy microscopic observation, without in reality giving any character as absolutely diagnostic between the corpuscles of pus, and the white ones of the blood. The fact that he treats so lightly, on a matter acknowledgedly so difficult, is strong presumptive evidence, warranting a right of questioning the validity of his statement.

In two cases which recently came under my notice, the blood carefully examined microscopically by myself, exhibited a large excess of white blood-corpuscles. But it is no use going further into the question, considering the paucity of evidence at hand.

The question of the condition of the blood in pyæmic subjects, must, in the present state of science at least, be regarded as a question *sub judice*, greatly requiring careful research for its solution, and promising a rich harvest to whosoever shall carry it out.

In concluding this critical analysis of opinions,* I cannot

* While these pages have been in the press, I have perused Professor Hughes Bennett's article on Leucocythæmia, in the first volume of the *Monthly Journal of Medical Science* for 1852, p. 331. It gives me pleasure to find that my criticism on Mr. Lee is precisely in accordance with that of Professor Bennett.

* Since writing the above, I have become acquainted with the important observations of M. Velpeau (*Léçons orales de Clinique Chirurgicale*, Bruxelles, 1841). If this essay had any pretensions to completeness, I should feel it incumbent on me to append a digest of the professor's teaching; under existing circumstances, this may for the moment be deferred.

forbear directing attention to the great desideratum for further investigation to which it points. The fact must be evident that the knowledge of this disease is comparatively recent, and that no sooner has attention been directed to it, than writers have been eager in theorizing on its nature without first studying the whole history of its phenomena. Let us inquire accurately into the causes, symptoms, and anatomical characters of pyæmia, and then, but then alone, will be the time to inquire into the *wherefore*. Obvious it is that the prosecution of any other plan than this must expose its followers to the danger, inseparable from being satisfied with a perception of partial truths, and forgetting that a discovery of the whole truth may prove any opinions deduced from prejudice and limited experience to be absolutely fallacious.

A task so incompletely achieved as this of mine is, stands in need of more excuse than I can plead for it. I feel that it is of no use to point in detail to the deficiencies of this paper, because so doing would be equivalent to writing a thesis on pyæmia—to doing, in fact, that which lack of time has prevented me accomplishing, and for not doing which I am constrained to plead indulgence. If, however, I have succeeded in drawing attention to the high import of the subject, and aroused to energetic action in its study, I have accomplished my greatest aim. I have spoken of a terrible and fatal disease, frequent yet almost unknown; and if I have not succeeded in imparting much information, I may at any rate say, that on this part I have not fallen below my aim. I am sufficiently repaid by the reflection that the few truths I have propounded, and the errors I have denounced, may incite some among you to endeavour to add to the former and lessen the number of the latter.

University College Hospital, November 1852.

ILLUSTRATIONS OF THE CAPRICES OF THE NERVOUS SYSTEM.

By M. BROKE GALLWEY, Surgeon, Royal Artillery.

In the Opening Address of the first number of the ASSOCIATION MEDICAL JOURNAL, it was stated that "short and pithy papers on practice and pathology are what are chiefly required". I therefore make no apology for the following *curt* communication, reserving the privilege of commenting hereafter upon the materials of which it is composed.

I. INTERMITTENT HYSTERICAL CHOREA.

A married lady, without children, eminently hysterical, and now and then affording in her own person strange and anomalous illustrations of that mysterious temperament, was attacked at midnight while in bed, and without warning, with sudden twitching of both upper and lower extremities, the muscles of respiration participating so much in the irregular action as to occasion considerable distress to that function. The tongue, however, could be protruded and withdrawn at pleasure, and evinced none of that peculiarity of jerk so characteristic of choreic phenomena in general. Although the muscular movements were limited to what might be strictly called *twitches*, and never rose to the importance of true choreic spasms, they were, nevertheless, exceedingly violent in character, and occasioned so much suffering to the subject of them, as to leave her exhausted, and bathed in perspiration. The attack lasted for three quarters of an hour. Throughout, the mind was clear, and consciousness unclouded. I administered stimulants, and the lady was quite well in the morning. Several weeks afterwards, she had a milder recurrence of the attack while in bed at night.

II. CURIOUS REFLEX PHENOMENA.

A lady, under my care for common cold, which had been accompanied by severe cough, the latter, however, having left her, had retired to her room for the night. She sat for some time by the fire undressed, before betaking herself to bed. Scarcely had she drawn the clothes around her when she was seized with a *sudden* and suffocating cough,

which no change of posture influenced or controlled. After enduring this for half an hour, she rushed out of bed for relief, and *immediately* found it at the fire-side. After a while she went to bed again, when precisely the same thing occurred to her a second time, with the like instantaneous cessation of the cough on again removing to the fire.

As I happened to be in the house at the time, I was summoned to this lady, who, in a casual remark which she dropped on the occasion, enunciated a physiological truth which cleared up the obscurity of the case at once; and this was, that she was certain it was the *coldness of her sheets*, which she felt to be excessive on the occasion, that had given rise to and kept up the cough. I had previously examined the state of the uvula, but found nothing whatever in the condition of that body to warrant my suspicion that the exciting cause of the cough resided there. At length, my patient enveloped her head and mouth in flannel, and returned a third time to bed, without the least recurrence of the cough. Although this last circumstance at first sight might favour the notion that it was to the inhalation of cold air, and consequent irritation of the air-passages, that the cough was in reality due, I have little doubt that the phenomena were true reflex ones, induced by the sudden contact of excessively cold sheets; because, had the air of that part of the room in which the bed stood been sufficiently irritating to originate the cough, it is reasonable to suppose it would not have delayed its operation until my patient had got into bed. At least, I think my physiology as much entitled to respect as that of those who explain the cry of the infant on its first arrival upon "this teeming stage of strife", to be dependent on the play of atmospheric air upon its surface; or of Ambrose Paré's physiology in relation to the cause of the variety of shape in the human nose divine; to wit, that its length and goodness simply depend upon the *softness and flaccidity of the nurse's breast*, and that the flatness and shortness of other noses result from the firmness and elastic repulsion of the same organ of nutrition in the hale and robust!

Devonport, February 17th, 1853.

BIBLIOGRAPHICAL NOTICES.

PRACTICAL SKETCH OF LOW INFLAMMATIONS. By S. F. STATHAM, Assistant-Surgeon to University College Hospital, London. pp. 31. London: 1852.

FEW subjects are more important than that which Mr. STATHAM has chosen to sketch in the present pamphlet; and especially in surgery, his peculiar department; it is absolutely necessary that the practitioner should understand low, or asthenic inflammation, and know how to treat it. The integrity of an organ, or the life of the patient, is often compromised by the injudicious use of lowering treatment, where an opposite system would have secured a happy issue. Mr. Statham has evidently studied this subject with great zeal and care, and his *brochure* contains many interesting observations, especially on the asthenic forms of surgical disease: but had he studied it in the works of others, as well as in the wards of his hospital, we think he would have less lightly appreciated the state of our present knowledge of a subject which has been much more closely attended to than he supposes. "I would claim, therefore," he says in his Preface, "that whenever inflammation is described, a sthenic (or ordinary) and a low type should be given, *which low type has hitherto been insufficiently recognized*." This assertion we refuse to admit; but we do not by any means on that account undervalue Mr. Statham's present contribution. We gladly thank him for much that is interesting in his description of various forms of unhealthy inflammation.

We are not certain that we understand all his *pathological* descriptions; as, for example, those contained in the following sentence:

"Similar pus-corpuscles to those first described occur in the inflammation of inflammatory mortification, and scattered in the serous fluid, ushering the same in its extension. The local signs of inflammation are those of flighty action, or dull, livid, *unimportant-looking* injection; an appearance of imperfect power, as it were, by too great diffusion or by actual want of circulation for the production of—what may justly be called in comparison—a healthy inflammation." (p. 10.)

To some of the opinions contained in his pages, we must demur; as, for instance, that acute rheumatism is one of the few diseases in which venesection is admissible (p. 9); or that the jaundice, so well known to accompany asthenic suppuration of the joints, is connected with hepatitis (p. 23).

The proof of the following doctrine would have been worth the whole pamphlet:

"It does not seem to be preposterous to consider *Asiatic cholera* as an erysipelatous inflammation of the intestinal mucous membrane. Such a supposition explains most satisfactorily all the symptoms and morbid appearances of this fatal disease. This is not a preconceived or *à posteriori* notion, but the best deduction I could make, four years ago, from the results of several months' independent labour." (p. 26.)

We think that diagnostic marks and indications for treatment, more precise than those with which Mr. Statham has furnished us, might be obtained by a closer analysis of the various species of unhealthy inflammation, of which we would suggest the following outline.

Unhealthy inflammation may be asthenic, typhoid, or specific.

ASTHENIC inflammation may be acute or chronic. It has two characteristics: *debility* (always present), which requires invigorating and tonic means, as good food, quina, and iron, even while local depletion may be needed; and (often) *irritability*, demanding narcotics and anodynes, as opium, camphor, and belladonna. The irritability is often the chief feature of the disease. But besides this, another most important division depends on the presence or absence of "*plasticity*" in the blood. Where that exists, as in strumous *iritis*, mercury may be useful, even in the face of great weakness; where it is not present, as in "diffuse inflammation", mercury is a poison.

TYPHOID inflammation is always acute, and always asthenic; but its great peculiarity is its connexion with poisoning of the blood, and the *tendency to coma*, which accompanies it. On these two points depend the utility of "antiseptics", as chlorine, and the frequent inadmissibility of opium.

SPECIFIC inflammation may be sthenic, asthenic, or typhoid, and may depend either on diseases of *malassimilation*, as scrofula; or of *poisoning*, as syphilis. In both, the so-called specific remedies are carefully to be kept in subordination to rational treatment.

Such is the *practical sketch* which we would propose. How difficult to diagnose, and how hard to treat these diseases are, those know best who have most anxiously studied them.

HOMŒOPATHY: ITS GLOBULES [Bubbles?] ANALYZED. By W. J. Cox. pp. 38. London: 1852.

THIS is a brief but very complete exposure of the chief absurdities and knaveries popularly embraced in the term homœopathy. The author proposes, in cheap pamphlets, to give "brief outlines of the most remarkable delusions of the day"; and the sixpenny tract before us is the first of the proposed series. The project deserves the support of the members of the medical profession, who might, at a trivial outlay, do much good by circulating works of this description. Some dupes have not the time or inclination to read, and many have not the power to understand such elaborate exposures of homœopathy as have been so ably furnished by Dr. Alex. Wood, of Edinburgh, and Dr. Routh, of London; but the most volatile, and the most indolent of the victims of modern charlatanism, might be tempted to glean instruction from the short and popular analysis of Mr. Cox.

PERISCOPIC REVIEW.

PSYCHOLOGY IN ITS RELATIONS TO PATHOLOGY, THERAPEUTICS, AND JURISPRUDENCE.

GUISLAIN'S LECTURES ON MENTAL PATHOLOGY.

[*Leçons Orales sur les Phrénopathies*. 1852. Vols. ii, & iii.]

WE continue our analysis of Dr. GUISLAIN'S work from p. 42 of the number for January 14th.

In considering the development of mental diseases, Dr. Guislain has adopted the opinion that barbarous nations present no other form than idiocy; that the proportion of the insane to the healthy population has greatly increased in modern times; and that, upon the principle that all mental conditions must be modified by the manners, laws, and social state of each community, this augmentation is to be traced to the absence of moral tranquillity, to the predominance of the emotions, and to the incessant succession of innovations and organic reforms. The man of the present day never conceives that his mission has terminated; he has a craving for new and powerful impressions; he worships the gold which he covets; and he finds that opulence creates and nourishes the passions. Dr. Guislain attributes still greater importance to the influence of the agglomeration of vast multitudes in cities upon the nervous system; and cites in illustration of his doctrine, that while the town of Ghent is burdened with one lunatic in every 302 inhabitants, the surrounding country presents not more than one in 1,474. In commenting upon the evils of wealth and luxury, he affirms that beggars—professional, hereditary beggars—never become insane. He does not, however, deny that poverty, deficient nourishment, and its other consequences, are abundant sources of alienation. In opposition to the views of Parent-Duchatelet, he holds that prostitution, and the course of life with which it is associated, constitute another fertile cause. But he protests against the dogma of Heinroth, that it depends upon man himself, upon his virtue or his vice, whether he is or is not to become deranged. He endeavours to show that there is no constant relation between crime and insanity; that mental infirmity falls generally upon the pure and the impure; and that it does not especially originate in minds of vicious and degrading tendencies, but also in individuals distinguished for the amenities and dignity of private and public life. He insists much on the prematurity of the present generation; the insubordination to discipline; the impressionability of sentiment; the superficial training and the frivolity of object of our educational systems, as playing an important part among the predisposing causes of alienation, and especially of feebleness and imbecility of intellect. It would appear that, although not obnoxious to this condemnation, the clergy and religious orders in Belgium furnish a larger proportion of insane than the general population. In the Great Beguinage, or nunnery, at Ghent, containing 650 females, twelve are insane, whereas the same number of unprofessed inhabitants of the town would produce only two. Dr. Guislain, in treating of the want of sleep as a cause of mental disorder, attaches greater weight to the anxiety, the fear, and other painful emotions, by which it is accompanied.

Contrary to what might have been expected from the convivial habits of the Flemings, madness arising from intoxication is found to be comparatively of rare occurrence in Belgium. The use of lead, and the abuse of tobacco, and especially of cigars, have, in Dr. Guislain's experience, been productive of insanity. While irregularities of menstruation almost invariably attend the incursion of alienation in the female, amenorrhœa should be regarded rather as a consequence than a cause of the constitutional disturbance. It is worthy of remark, that the non-criminal or involuntary desire to steal is most frequently found in individuals who are pregnant, or where the uterus is in an unhealthy condition. That insanity frequently follows intermittent fevers is conceded; but Dr. Guislain is disposed to controvert the German view, that where malaria exists mania assumes a regular intermittent type. As Dr. Guislain is an acute observer, residing in a marshy district, his evidence is worthy of attention. It is singular that while the connexion of pellagra and skin diseases with insanity is fully investigated, the influence of scrofula and syphilis is dismissed in four lines. The long continued use of iodide of potassium is conceived to have produced the general paralysis of the insane. We are somewhat astonished to meet, in this ample etiology, our antiquated friend *lunar influence*, and upon the authority of Engelken. Those who desire more satisfactory information upon this sub-

ject, we refer to a series of tables in the Annual Reports of the Lancaster Asylum.

Dr. Guislain conceives that the overthrow of reason cannot legitimately be traced to one cause, or to the last of a series, but to external circumstances, or internal changes of varied nature and long in operation. His pathology of this class of diseases may be summed up in the phrase—the painful impression of our moral sense. We do not become insane in the exercise of intellect, in the cultivation of the arts or sciences, or in the most unbridled indulgence of imagination, provided the excitement does not engender hatred, jealousy, or disappointment, and does not affect the means of existence. "Our emotions are at the bottom of the greater number of causes." "Alienation, rightly viewed, is a pain, a phrenalgia." This suffering, in the same way as corporeal pain, induces reaction, which is observed in the loquacity, restlessness, and vituperations of the patient. Dr. Guislain is convinced that the mere expressions of the ideas—the vociferations—act as a moral sedative. Mania may be regarded as a healthy crisis; and confessedly tends more frequently to health than other forms of alienation. He is opposed to the theory which explains mental diseases as the result of visceral irritation; to that which regards them as inflammatory; to that which traces them to poisoned fluids, or to a special condition of the immortal spirit; and he endeavours to elude the necessity of enunciating a theory by identifying them with the neuroses. To whatever explanation we are driven, he conceives that the element of debility must enter into the consideration.

The curability of insanity is inferred to be forty-five per cent. upon the admissions, including among these all cases of relapse; and it is supposed to reach its maximum in mania, and its minimum in delirium, dementia, and affections of the will. In mania, melancholia, and ecstasy, he has been accustomed to regard profuse perspiration, eruptive diseases, hæmorrhages, pulmonary affections, and even the secretion of tears, as critical.

In the treatment of these maladies, our author insists upon rest and tranquillity as the first and even the most effective agent. He does not confine this recommendation to the removal of all sources of moral perturbation and disquietude, to the establishment of moral calm and composure; but enjoins physical immobility, and prescribes the horizontal position and repose in bed: he condemns exercise to the extent allowed in British asylums, and justifies restraint upon the same grounds. To promote this object, prolonged baths are found to be useful in recent cases; in those depending upon suppression of the catamenia; in simple melancholia; in mania-melancholia; and in these forms when associated with diseases of the skin. Dr. Guislain condemns recourse to general blood-letting in every species of mental alienation. Rigid in his exclusion of relatives and friends during the acute or early stage of derangement, as their presence is eminently calculated to agitate and excite, he speaks most favourably of such intercourse towards the decline of the malady, or when it has become chronic, as calming and restorative. He speaks of liberation as a means of cure; and finds that of 336 individuals who were discharged from the asylum uncured, 33 maniacs appeared to have been restored to reason by the act of reunion with their family.

Of the efficacy of religion and worship in leading the mind to healthy views, and in tranquillising those who cannot so be led, he entertains the opinion which is now predominant; but he introduces two specialities, in sanctioning confession and the substitution of religious orders for lay attendants. He "does not hesitate to state, that he recognises in the cenobite hospital-servant such a superiority as excludes all idea of comparison." After quoting the testimony of various superintendents of the insane to the same effect; after discriminating between the influence of monks and nuns who usurp the functions of the physician, and those who prove his willing fellow-labourers and instruments; after contrasting strongly the class from which such recluses spring, the motives by which they are actuated, and the moral training to which their vows have subjected them, with the antecedents and qualifications of ordinary keepers,—he concludes, "the action of such a medicine is superior to that of all other medicines". In establishments directed by religious corporations, it has been observed, we are told, that the insane do not swear, and are infinitely less noisy and insubordinate than where the nurses are mercenaries.

Dr. Guislain comments upon the solitude during night, the cries and turbulence of other patients, and the indifference and inattention of servants, as valid objections to isolation; but he nevertheless attributes 80 out of 100 cures principally to the influence of this agent, or, in more unvarnished phrase, of cap-

tivity. He further broadly claims intimidation as an adjuvant; devotes a chapter to the curative effects of menaces and fear; cites cases in which he had carried out these principles successfully, by threatening patients with destruction, and even by producing the sensation of suffocation; and concludes by enumerating the authority and discipline of the medical governor, seclusion, the douche, immersion, and physical restraint, as the modes in which they should be carried into execution.

It will astonish the psychologists of this country to find that a physician, distinguished by his vast experience, and by his enlightened humanity, should advocate restraint, not as an unavoidable but painful alternative, not merely as the means of facilitating the application of other remedies, but as expedient, justifiable, and curative. He is not ignorant of the practice adopted in England: he boldly enters into the controversy upon the subject, now fortunately terminated; and, in the face of the supposed triumph of his opponents, adduces a number of plausible, if not new arguments and illustrations in favour of mechanical means of economising the strength of the restless, of compelling recourse to the horizontal posture in night-watchers and walkers; in protecting suicides and mutilators from their own designs; in correcting tendencies to nudity, to masturbate, to destroy, and to burrow; and in producing moral impressions.

We find Dr. Guislain equally opposed to the general introduction of amusement as a remedial agent. He admits the utility of the tuition of music, but shrinks from a concert as a heresy, and regards dramatic representation as an absurdity. He looks with jealousy on labour, except in the treatment of mania; and reproaches all violent and even active exertion, in other forms of alienation, as tending to accelerate the circulation, and as inconsistent with that calm which it is his object to establish: yet he admits that indolence and immobility predispose to paralysis, especially in the fatuous; to obesity and constipation in all; and we may add, to local congestion, as well as to mental hebetude and enfeeblement.

Dr. Guislain's principles of classification are founded upon the external condition, rather than the mental state of the patient. He divides the insane into—1, the convalescent, comprehending those approaching sanity; those temporarily lucid, the infirm, and the bed-ridden; 2, the quiet, such as melancholics, ecstasies, tranquil maniacs, the hallucinated, and imbeciles; 3, the agitated, with whom are arranged despairing melancholics, suicides, gesticulators, singers, the loquacious, the restless, etc.; 4, the turbulent and destructive; 5, the fatuous; and 6, the dirty. He signals a great diminution of the latter class on the continent, although, in the establishment under his own care, they have increased. In Britain, it appears, on the authority of the Commissioners in Lunacy, the proportion is 27 per cent.; while in France, 10 per cent. of males, and 12 per cent. of females, is the proportion observed where a suitable diet, ventilation, and judicious supervision, are carefully provided. This class may, like congenital imbeciles, be educated, and restrained to habits of cleanliness and propriety. Where inattention to the calls of nature is the consequence of relaxation or paralysis of the sphincters, great benefit has been derived from the exhibition of the sulphate of strychnia. In Dr. Guislain's hands, this remedy appears to have succeeded in one case only of forty three in which it was tried; and the effect produced is referred, in part, to the other agents employed simultaneously; and was, in all probability, due rather to mental training than to physical invigoration. He most justly regards bed-sores in the fatuous, and in all classes of the insane, as indicating exhaustion of the nervous centres, and peripheral death. In cases of dementia, supposed to depend upon serous infiltration of the nervous tissues, he has found iodide of potassium a most powerful remedy; and even conceives that it has availed in arresting the progress of the congestive stage of softening. He speaks in the same eulogistic terms of the efficacy of vesication, and especially of the application of the antimonial ointment in chronic mania which has continued for some months, and resisted the influence of tepid bathing and other measures. In monomania, he enumerates various modifications of moralisation, of exposing and thereby expelling erroneous ideas, by argument, by repeated demonstration of the truth, by stratagem, and by the introduction of new trains of thought through the instrumentality of occupation, of amusement, and of the cannabis Indica; but he evidently places greater reliance upon the potency of depressing or painful impressions; such as the water-cure of M. Leuret, where the fear of drowning, and the hunger-cure of Hoffmann, where the fear of starvation extorted confessions of error and extravagance, and imparted, it is affirmed, sound and rational views.

This leaning towards heroic treatment, and the preference

mechanical to moral agents, is perhaps explicable on consulting the results of Dr. Guislain's long experience, which have been reduced to a tabular form. Of 100 cures, he believes that 2 might be fairly attributed to douches, depletions, and the use of irritants; 3 to the restoration to liberty; 4 to seclusion; 6 to narcotics; 7 to diet; 10 to hot and cold bathing; 40 to labour and other means of distraction; and 80 to the mere influence of isolation and its attendant circumstances.

MOREL'S ESSAY ON MENTAL DISEASES.

[*Etudes Cliniques. Traité Théorique et Pratique des Maladies Mentales.* 1852.]

THIS is a systematic work which has grown out of a course of clinical lectures delivered by M. MOREL, chief physician to the Mareville Asylum, an institution of large size at Nancy, in France. The author has followed the example of Esquirol and Morison, in giving engravings of many of the patients to whose cases his observations are directed. There are plates of imbeciles with destructive, homicidal, and erotic tendencies: of idiots, maniacs, monomaniacs, and ecstasies. These, however, must be accepted rather as individual portraits, than as pathognomical representations.

In treating of congenital idiots, M. Morel adds to the more familiar features the presence of strabismus; the prominence and irregular shape of the external ear; the absence of the beard; and the prevalence of a bronze or copper colour of the skin. He has found that, in idiots and persons of imperfectly developed mind, as well as in cretins, there is a tendency to hypertrophy of the mammary and thyroid glands. He further records oedema of the inferior extremities, and the exhalation of a disagreeable odour, which no attention to cleanliness can remove, as pathological conditions frequently met with in idiots and imbeciles. Epilepsy is noticed as a frequent aggravation of the misfortunes of these rudimentary beings. M. Morel has observed that, in regions where goitre and cretinism prevail, there is likewise a greater number of idiots and imbeciles than in healthy districts. He likewise regards it as demonstrated, that in those countries where there is the largest number of illegitimate births and of offences proceeding from misery and drunkenness, there will be found the largest amount of mental and physical degeneration. Imitation he regards as the most characteristic power of the limited capacity which partial imbeciles possess, and as that upon which all attempts to educate or to cure must be founded: but he is persuaded that, in conjunction with those feeble rays of intelligence which are observed amid the general darkness, many complicated and rational acts are performed *instinctively*. Among infants affected with epilepsy and partial feebleness of intellect, may be detected those germs, those tendencies, which, if unchecked, are developed into great crimes as well as great virtues.

In considering the etiology of the different phases of mental weakness, and detailing the influence of difficult parturition, the use of instruments, insufficient nourishment, and insalubrious dwellings, he attaches great importance to the pre-existence of deafness. He further states, that deaf-mutes abound wherever imbecility prevails. In an adjoining commune containing twelve hundred inhabitants, fifty families contain members affected with one or more of the congeneric maladies,—imbecility, idiocy, goitre, cretinism, and dumbness. When speaking of fatuity as the consequence of other descriptions of insanity, M. Morel expresses great confidence in the effects of the sulphate of strychnia in cases of incontinence of urine and feces: the other means being cold affusion to the spine and nates; and the internal administration of iron and cod-liver oil. These observations are valuable; because it is believed that at Mareville the class of dirty patients has been reduced to its minimum. M. Morel recounts the restoration of a fatuous patient to reason after the duration of disease for fifty-two years: and of another who, mute and degraded and apparently unconscious for five years, summoned the priest to his bedside, a few hours previous to death, and arranged his affairs in a rational and judicious manner.

In considering the influence of age in the production of derangement, various authors are quoted as supplying instances of the disease in individuals under eleven years. Greding has recorded a case of destructive mania, in an infant of eighteen months. Homicidal mania is described as occurring at eight years of age; pyromania as occurring chiefly between fifteen and eighteen, and in females; and suicidal mania as having been observed at twelve. Thirty-one children are reported to have committed suicide in Berlin, between 1812 and 1821.

At this point is detailed an epidemic theomania, which affected

children and youths in the thirteenth century. It is called in history the children's crusade. The apostle was a shepherd boy. His delusions, that he was the inspired messenger of God, and that his mission to preach a crusade was recognised and revered by the genuflexions of the sheep intrusted to his care, found a response in the fervid piety of the age. He received the *oriflamme* from St. Denis; and thirty thousand children of both sexes, of various ages from eight to twelve years and upwards, of princely as well as peasant nurture, rushed to his standard, with an unanimity of impulse and disregard of ordinary and prudential and intelligible considerations and motives, only seen on such occasions. The voices of home were drowned in the cry of "Jerusalem"; parental authority was defied in the wild instinct of imitation and of vague superstition: the mirth and games of childhood disappeared in the shadow of the Holy Sepulchre; and enthusiasm gave a sudden but morbid maturity of purpose and fortitude, and of physical strength, to the plastic but undeveloped powers of infancy. Want, disease, and death, decimated these bands of schoolboys during a march of many hundred miles; but, on arriving at the Mediterranean, they still cherished the delusion that the sea would recede, and its bottom be to their footsteps as dry land. Visions, prodigies, and imaginary miracles abounded among the delirious host; and the excitement was accompanied by chorea, convulsions, and other nervous affections, which have been observed in similar religious epidemics. This romance of disease is more fully described in the last number of the *Journal of Psychological Medicine*, p. 118, in a translation, it is presumed, from Ideler; and in Vol. III., p. 441, of Robson's translation of Michaud's *History of the Crusades*.

REPORTS OF SOCIETIES.

ANNIVERSARY MEETING OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY,

TUESDAY, MARCH 1st, 1853.

A few minutes after four o'clock, Mr. HODGSON, the President, took the chair, and announced that the ballot was open. Amidst some confusion from members going forward to deposit their printed lists in the balloting-box,

Dr. O'CONNOR said that, before the ballot proceeded, he wished to ask a question, viz., whether a current rumour were correct, that a gentleman, occupying a distinguished position in the profession in London, was solicited by the Council to be announced as their nominee for the new Council; and that, although he consented, the nomination list, to his astonishment had appeared without his name. Dr. O'Connor wished to know if the report were correct; and if so, upon what ground exclusion had been resolved upon at the eleventh hour?

Mr. CHARLES HAWKINS protested against the time of the Society being occupied with what he thought was an irrelevant discussion. It would be a most inconvenient and a most improper course, to allow the qualifications of candidates, and the motives of the Council, to be made subjects of discussion.

Dr. CORMACK, without the slightest reference to motives or persons, wished to repeat the question of Dr. O'Connor, in such a way as would enable him to know whether gentlemen could be eligible as Fellows of the Society, and yet be ineligible as Members of the Council. He therefore respectfully asked, whether any Fellow was ineligible as a Member of Council? He did not wish to ask the question with reference to the comparative merits of individuals, but simply as one regarding the constitution of the Society, and the privileges of Fellows.

The PRESIDENT said that, without any disparagement to the eminent individual referred to, he had no objection to state, as his opinion, that there were some Fellows in the Society who ought not, from various causes, to be placed upon the Council.

Dr. BASHAM (one of the Secretaries) read a passage from the charter, relating to the election of Members of the Council.

Dr. O'CONNOR observed that, from what the Secretary had read, the exclusion of the gentleman to whom he had referred—a gentleman highly esteemed and respected by all who knew him—was undoubtedly a vote of censure upon him. His (Dr. O'Connor's) object in referring to the matter at all, was to expose the improper manner in which the Council of the Society was nominated. The objection which was made to Professor Murphy—his not having a London title—held good against a nominee of the Council, Dr. Balfour.

The PRESIDENT believed that Dr. Balfour was a Fellow of the College of Surgeons of England, and was therefore in a different position from Dr. Murphy, who did not belong to a London College.

Mr. QUAIN thought that he had a statement to make, which might smooth the troubled waters. He had taken part in the discussions on this subject at the Council Board; but with what he had there said, it was not his intention to trouble the Society. He wished, however, to state, that he had had some communication with the individual first referred to by Dr. O'Connor, and that gentleman had said that, if the rules of the Society excluded those who did not possess an English qualification, the decision of the Council was a correct one.

The PRESIDENT asked Dr. O'Connor if he intended to propose a resolution on the subject.

Dr. O'CONNOR replied that it was not his intention to do so. The object he had in view was gained; viz., to expose the highly improper and unwarrantable acts of the Council in the nomination of officers.

After some remarks from the PRESIDENT and Mr. CHARLES HAWKINS, the subject was allowed to drop; and Members were requested to deposit the lists in the ballot-box; the balloting being allowed to go on till five o'clock. In the meantime, the other business proceeded.

TREASURER'S REPORT. The following is an abstract:—

RECEIPTS.—*Ordinary Income.*

	£	s.	d.
300 Annual Subscriptions	945	0	0
27 Admission Fees	170	2	0
3 Composition Fees for Transactions	18	18	0
2 Ditto, in lieu of further Annual Payment	10	10	0
Fines	4	1	0
Longman and Co., for Transactions sold	86	9	2
Interest on Stock	61	5	11
Rent of Stable, and Rent from Society of Widows, etc., of Medical Men (half-year)	56	2	6
	£1,352	8	7

Extraordinary Income.

Stock sold by order of the Society	246	17	6
Sale of back Volumes of Transactions	27	13	0
	274	10	6
	£1,626	19	1

Payments	1,627	2	6
Receipts	1,626	19	1

PAYMENTS.—*Ordinary Expenditure.*

House—Rent, Rates, and Taxes	207	3	2
Lighting and Coals	37	10	5
Repairs	16	14	4
Stationery and Accountant	34	8	3
Petty Cash	73	6	0
Sub-Librarian's Salary	140	0	0
Page—Wages and Clothes	45	10	6
Library	217	17	11
Transactions—Vol. xxxv.	256	5	10
Investment of Composition Fees	10	10	0
	£1,039	6	5

Extraordinary Expenditure.

Debt to Treasurer from last Year	283	11	1
Furniture—Bookcase, etc.	59	15	0
Purchase of Stock, in addition to 10l. 10s. above stated	244	10	0
	587	16	1
	£1,627	2	6

REPORT OF THE COUNCIL. The Secretary then read the Report of the Council, which represented the affairs of the Society as in a highly prosperous condition. Fewer members than usual had entered; but this circumstance was explained by supposing that the new method of electing Fellows had not become generally known.

Mr. CHARLES HAWKINS thought that this was a proper occasion for calling attention to the method of admitting Fellows to the Society. According to the present plan, practically it was necessary to vote for all or none. After some observations upon this subject, he concluded by moving a recommendation to the Council to consider the propriety of balloting for candidates individually, and not collectively.

After some discussion, the terms of Mr. Charles Hawkins's recommendation were modified in this way: that the Council should be requested to take the whole subject of the election of Fellows into consideration.

PRESIDENT'S ADDRESS. After congratulating the Society on its present prosperous condition, he gave biographical sketches of the Fellows who had died during the year: viz., Mr. Vincent, Mr. Dalrymple, Dr. H. Mayo, Dr. George Gregory, Dr. Pereira, Dr. John Taylor (of Huddersfield), and Dr. Merriman.

After the President's address, the result of the ballot was declared:—

PRESIDENT: *James Copland, M.D., F.R.S. VICE-PRESIDENTS: James Alderson, M.D., F.R.S.; *Thomas Alfred Barker, M.D.; *Martin Ware; *Benjamin Phillips, F.R.S. TREASURERS: Robert Nairne, M.D.; Richard Quain, F.R.S. SECRETARIES: William R. Basham, M.D.; *Holmes Coote. LIBRARIANS: Henry Pitman, M.D.; James Dixon. OTHER MEMBERS OF COUNCIL: *Thomas Addison, M.D.; Thomas Graham Balfour, M.D.; *George Chaplin Child, M.D.; *William Dingle Chowne, M.D.; *Mervyn A. N. Crawford, M.D.; William Bowman, F.R.S.; John George French; *James Randal Martin, F.R.S.; Edward Stanley, F.R.S.; Thomas Tatum.

NEWS AND TOPICS OF THE DAY.

MUNIFICENT GIFTS TO MEDICAL INSTITUTIONS. M. ORFILA has read the following letter before the Academy of Medicine of Paris:—"I do not wait, as is generally the rule, till death has removed me from among you, to assign the sum of £4,800 to different public establishments. I have two reasons for acting thus: first, because it is of some importance that the institutions to which I refer should as soon as possible reap the benefit of the donations which I am offering; and secondly, because I thought that my presence would be of some use to overcome any difficulties which might arise during the carrying out of my plan; or perhaps in order to modify the latter, if the necessity of doing so were clearly demonstrated. I shall not attempt to enter into the reasons which have induced me to give the preference to certain institutions over others; it will be sufficient for me to state, that by giving £2,400 to government for the completion of the museum which bears my name, it is my intention to endow France with a scientific collection which will be unparalleled; and also to afford students in medicine a new proof of the sympathy and good-will with which I have always regarded them. I am also anxious to show them how grateful I feel for the very flattering attention they invariably have given to my lectures for the last thirty-four years. I am anxious, for this reason, that no misapprehension should exist regarding my motives; and have directed the following inscription to be placed over the principal entrance to the museum:—

"To Students in Medicine. I founded this Museum, in 1845, for promoting medical studies, and solely to be useful to yourselves." ORFILA.

"I have thought it right to found a small annuity in favour of the keeper, who has always rigidly attended to his duties. I also institute two prizes, one to be given by the Academy of Medicine (£80), the other by the School of Pharmacy (£40), on subjects which have fixed my attention all through life. I have thus no other ambition but that of serving a science to which I have always remained faithful, without allowing myself to be led astray by politics. I give to the Preparatory Schools of Bordeaux and Angiers, £40 to the former, and £88 to the latter, to show how I approve of this kind of schools, which were organised upon a proposal of mine. To the Benevolent Medical Association of the Department of Seine, I give £16 a year, in proof of the high estimation in which I hold this society, which I am proud of having founded in 1833."

M. Orfila mentioned various other acts of kindness and benevolence, of smaller importance, and received at the end of his discourse the hearty and unanimous applause of the members present. The Academy decided that thanks should be tendered to M. Orfila by a deputation.

* Those gentlemen to whose names an asterisk is affixed, were not at the Council last year, but most of them have been on it in former years, and very frequently.

NORTH PANCRAZ PROVIDENT DISPENSARY FOR THE INDUSTRIAL CLASSES. The third annual meeting of this institution was held on the 28th January last, at the Dispensary in Hawley Crescent, Camden Town; the Rev. David Laing, M.A., F.R.S., Treasurer, in the chair. From the report presented by the Secretary, it appeared that the institution has been making satisfactory progress. 251 members' cards have been issued during the past year, and the present number of members amounts to 960. The donations and subscriptions of the public in aid of the society, amounted, during the year, to £94:3:3; the members' payments to £258:11:5; total, £352:14:8. The expenditure has been as follows:—General working expenses, £119:15:2; medical department, £231:4:1; total, £350:19:3. During the year, there were 1891 medical cases, and 69 midwifery cases: the deaths were 18. A special general meeting was directed to be called, for electing an additional medical officer, and an honorary consulting physician, in room of Dr. George Gregory, deceased.

NEW EQUITABLE LIFE ASSURANCE COMPANY.

The following is the published Report of the Directors, read at the Second Annual General Meeting of policy and shareholders, on Thursday, February 17th, 1853; Sir Charles Hastings, M.D., D.C.L., in the Chair.

The Directors of the New Equitable Life Assurance Company, in presenting their Second Annual Report to the policy and shareholders, feel that they have only to describe the extent of business actually transacted by the company, to demonstrate most conclusively its triumphant and unparalleled success.

The New Equitable Life Assurance Company, having been completely registered, commenced operations on the 1st of February, 1851. Between that time and the 31st December, a period of eleven months, the directors issued 308 policies for the sum of £98,500. The annual premiums on these policies amounted to £3,483.

During the whole of that period not a death occurred amongst the assured.

From the 1st of January, 1852, to the 31st of December, 1852, the directors received 420 proposals to assure £202,845. Out of this number of proposals, 369 policies were issued, assuring the sum of £180,355. The remaining proposals, for assuring £22,490, were either declined by the directors, or were not completed at the end of the year. The annual premiums payable upon the 369 policies issued in 1852, amounted to £7,169.

The only claim made upon the company during the year 1852, was one for £300 in December. Thus, no claim occurred until one year and eleven months from the date of the establishment of the company.

The entire number of proposals received from the date of the first policy in February 1851, to the 31st of December, 1852, was 834, for assuring £349,122. The number of policies actually issued in the above period, was 677, for assuring the sum of £278,855; and the income derivable from these policies in premiums amounts in the whole to £10,652:12:2 per annum, the average amount of each policy being £411.

The directors may be allowed to add, that in no like period of time since the establishment of the company, has the number of proposals been greater than from the 1st of January, 1852, to the present date. The number of lapsed policies has been few, and of inconsiderable amount, during the past year; and, indeed, from the commencement of the company, the same remark applies.

The directors may point to the number of proposals either declined by them during the year, or still remaining under consideration, to show that every care has been taken in the selection of lives. This is further proved by the fact, that the single death which occurred amongst the large body of policy-holders, during a period of nearly two years, has been greatly below the average even of selected lives.

The distinguishing principle of the New Equitable, since its original foundation, has been the recognition of medical testimony as the most substantial and certain basis for all life assurance transactions. The directors have found the best proofs of the soundness and wisdom of this principle; on the one hand, in the daily increased importance attached to medical opinions by life offices which had hitherto refused all remuneration to medical practitioners for their reports; and on the other, in the zealous and powerful support the New Equitable has received from the medical profession. They may also observe, that additional experience has but confirmed the value which, from the first, they attached to their system of medical evidence.

After reflecting most patiently and deliberately on the nature of medical testimony, and the influence it must ever exercise in conducting life assurance proceedings to safe and successful results, the directors determined on consulting the medical attendant of the party proposing the assurance, if a legally qualified practitioner, as the medical adviser of the board, and on awarding an adequate consultation fee for every medical report. An ample experience now enables the directors to refer, with feelings of peculiar satisfaction and pleasure, to the highly important precedent thus established by the New Equitable Life Assurance Company.

In the progress of this company to its present unquestionably high position, the directors have necessarily encountered the difficulties and obstacles which a field crowded with able and active competitors was sure to furnish. But, experiencing daily the confidence of the public, and, above all, of the great body of the medical profession, the directors felt every encouragement to advance, and they now refer to the detailed history of the transactions of the company for the best proofs of the success of their labours.

In the month of November last, the period having expired for which the late chairman of the board had undertaken to occupy his office, the directors being anxious to elect a president whose position, character, and attainments commanded the respect of the profession, addressed the following requisition to Sir Charles Hastings:—

449, Strand, Charing Cross, London, Nov. 4, 1852.

To SIR CHARLES HASTINGS, M.D., D.C.L., &c. &c. The chairman of the New Equitable Life Assurance Company, much regretting that his professional avocations, coupled with an engagement at another life office, where he was recently elected to succeed the late Sir Charles Forbes, as physician, made it incumbent upon him to resign his present office, had the pleasure of proposing at the board on Thursday last, the 28th day of October, the following resolution:—

Moved by the chairman, Robert Lee, M.D., F.R.S., seconded by Thomas Wakley, Esq.—That Sir Charles Hastings, M.D., D.C.L., be requested to favour the directors by accepting the office of Chairman of the Board of Directors of the New Equitable Life Assurance Company, an office about to become vacant by the resignation of the present chairman; and that a requisition, signed by the chairman and every other director, be presented to Sir Charles Hastings, expressed in such terms as the board may think proper.—Carried unanimously.—Entered on the minutes.

In conformity with the spirit and terms of this resolution, we, the undersigned, consisting of the entire Board of Directors, now request that you will confer upon the New Equitable Life Assurance Company, the honour and advantage which must arise from your becoming the chairman of the board. It is proper that we should state, that, although the company has been established for only the short period of twenty months, its income exceeds £9,400 per annum; and, from the promises of support and encouragement which the directors are continually receiving, they believe that few life assurance offices will issue a greater number of policies than the New Equitable in future years. It is right also that you should be informed, that when this company was established, the directors resolved to act upon the principle of regarding medical testimony as the safest guide in forming a judgment relative to the conditions on which policies should be granted. They, therefore, unhesitatingly recognised the practitioners named by the proposers for assurance as the medical advisers of the directors, who have considered it to be a conscientious duty, to award the medical gentlemen thus consulted, an adequate fee for every official medical report.

An experience of twenty months' duration, has been sufficient to convince the directors that the course of policy which they determined to adopt, was founded on correct premises, the results having been in the highest degree gratifying.

You, Sir Charles, by accepting the office of trustee, sanctioned the principles which were adopted for regulating the proceedings of the company; we, therefore, hope that you will readily consent to become more closely connected with its management and successful operations, by occupying the highest appointment that the directors can confer.

Being fully aware of your high personal character, unsullied reputation, and intimate professional connexion with a vast number of the most respectable members of the medical profession practising in this country, we believe that your acceptance of the presidential chair, at our board, would be of signal advantage to the interests of the company, and would also have

the effect of facilitating, in a very great degree, the recognition, by other and long-established life assurance companies, of the just claims of the members of the medical profession.

As we are strongly impressed with these views and opinions, we conclude by emphatically and respectfully requesting that you will honour the company by accepting the office of Chairman of the Board of Directors.

(Signed) ROBERT LEE, M.D., *Chairman*.
GEORGE BEAMAN, *Deputy Chairman*.
And all the other Directors.

The directors heartily congratulate the policy and shareholders on the success of this application. Sir Charles Hastings is now the Chairman of the Board; and since his election a local board has been established, under his auspices, at Worcester, under the title of the "Worcester City and County Board of the New Equitable Life Assurance Company."

The directors have much pleasure in placing before this meeting the testimony of F. G. P. Neison, Esq., the justly distinguished actuary; a testimony given after a careful inquiry into the affairs of the New Equitable:—

25, Pall Mall, London, 31st January, 1853.

I have carefully examined the balance sheet of the New Equitable Life Assurance Company, containing a statement of the receipts and disbursements for the year 1852; and having regard to the unusually large amount of business transacted by the company in its second year, the current working expenditure appears to me to be very moderate; and, in fact, I do not see how, consistent with the effective management and extension of the company's business, the general expenses could be safely lessened.

I have also attentively examined the other documents submitted to me by the secretary, showing the nature and extent of the assurances effected; and from these I consider the progress of the society most satisfactory and encouraging.

(Signed) F. G. P. NEISON, *Actuary*.

The directors cannot conclude the present report without most sincerely congratulating the medical profession, and the policy and shareholders, on the prosperous condition of the New Equitable Life Assurance Company.

(Signed) CHARLES HASTINGS, M.D., *Chairman*.

17th February, 1853.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were members of the Association.]

BRYANT, Edward, Esq., surgeon, at 44, Acacia Road, St. John's Wood, aged 70, on February 27th. He had been fifty-two years a member of the Royal College of Surgeons.

DALTON, William, M.D., at Lowther Street, Carlisle, aged 35, on January 11th.

FARISH, James, M.B., at Lancaster Place, London, on February 19th. He was the eldest son of the late Professor Farish, of Cambridge, whose mathematical ability, and intimate acquaintance with the laws of physics and their practical application, were possessed by his son. After graduating in arts at Cambridge, he completed his surgical education at St. Bartholomew's Hospital, acting as dresser to Mr. Lawrence, and subsequently as his house-surgeon. He afterwards obtained a highly respectable practice in London. He was one of those who paid as much attention and care to the poorest as to the highest. Mr. Farish was an exact classical scholar, and a deep mathematical one. He was well read, and of large general information; his mind was clear, discriminating, and argumentative. He was the intimate friend of many distinguished scholars and men of note. But the highest parts of his character were his delicate conscientiousness, his *incorrupta fides*, his *nuda veritas*; and a warm heart tempered the natural sternness and self-reliance of his character. His last illness was long, and some of its symptoms very distressing; but he bore it with fortitude, and looked forward to its termination with a serenity founded on Christian faith. He was a close and critical student of the Bible; and his religion was not merely speculative, but was firmly founded on the careful study and constant practice of its duties.

*SIBBALD, William, M.D., at Maidstone, aged 63, on February 15th. Dr. Sibbald graduated at Edinburgh in 1809, and in August 1810, entered the medical department of the army. During the campaigns of 1813 and 1814, he served in the Peninsula, being present at the battles of Orthes and Tou-

louse. In June 1814, he accompanied the expedition to New Orleans; and on his return in 1815, joined the army at Brussels, soon after the battle of Waterloo. In this year he became Staff-Surgeon. In 1817, he went to the Mauritius; and, after a few years, he proceeded on promotion as Deputy Assistant-Inspector to Ceylon. On retiring, in July 1833, with the rank of Physician to the Forces, he settled at Maidstone; and was soon afterwards appointed Physician to the West Kent Infirmary, the duties of which office he discharged till a week before his death. He was also Visiting Physician to the Kent County Lunatic Asylum, and Consulting Physician to the Kent Ophthalmic Hospital at Maidstone. He had received the war medal with three clasps.

SMITH, Francis, M.D., lately, in London, aged 48.

*WINTLE, Frederick Thomas, M.D., Resident Physician to the Warneford Asylum, Oxford, at Cheltenham, aged 50, on February 14th.

ADVERTISEMENTS.

NEW AND IMPROVED EDITION OF THOMSON'S CONSPECTUS,

WITH THE NEW PHARMACOPŒIAS INCORPORATED.

An entirely New Edition, in 18mo., price 5s. 6d., cloth; or in roan with tuck and gilt edges as a pocket-book, price 6s. 6d.

Thomson's Conspectus of the Pharmacopœias. Sixteenth Edition, revised throughout and corrected to 1852: Containing all the Alterations and Additions of the New London Pharmacopœia; and a copious Appendix. Edited by DR. EDMUND LLOYD BIRKETT, F.R.C.P. Lond., Physician to the City of London Hospital for Diseases of the Chest, and Curator of the Museum of Guy's Hospital.

Just Published, in 8vo., with Woodcuts, price One Guinea.

THOMSON'S LONDON DISPENSATORY. 11th Edition, corrected to 1852 by DR. A. B. GARROD.

London: LONGMAN, BROWN, GREEN, and LONGMANS.

THE PHARMACOPŒIAS IN ENGLISH.

In One Thick Volume, post 8vo., with numerous Woodcuts and Diagrams, price 18s., cloth.

A Translation of the New London

PHARMACOPŒIA, including also the NEW DUBLIN and EDINBURGH PHARMACOPŒIAS; with a Full Account of the Chemical and Medicinal Properties of their Contents: forming a complete *Materia Medica*. By J. BIRKBECK NEVINS, M.D. Lond., M.R.C.S., and L.A.C.

"Of the works that have been published since the appearance of the Pharmacopœia in February 1841, that of Dr. Nevins . . . is the most ample, the most complete, and we should think, upon the whole, the most serviceable. It is a book for the table of the consulting-room, the surgery, and laboratory; and shops cannot do without it."—*Edinburgh Medical Journal*.

London: LONGMAN, BROWN, GREEN, and LONGMANS.

On April 1st will be Published PART I of the

Glasgow Medical Journal, to be

continued Quarterly. Subscription Twelve Shillings per annum, payable in advance, for which sum it will be sent post free to all parts of the United Kingdom, and the greater number of the British Colonies.

Prospectuses post free, on application to

RICHARD GRIFFIN & CO., Glasgow.

The Valuable Medical, Obstetric,

and GENERAL LIBRARY (about 3000 volumes) of the late Dr. MERRIMAN.—By MR. LAHEE, on the PREMISES, No. 34, BROOK STREET, GROSVENOR SQUARE, on FRIDAY, MARCH 18, and following day, at ELEVEN, for TWELVE o'clock precisely, comprising a unique Collection of Obstetric works, and on Medicine, annotated in MS. by the late Dr. Merriman, and comprising in the Miscellaneous works—Belzoni's Travels—Hudibras in folio—Bryan's Dictionary of Painters, &c.—the Bridgewater Treatises—Publications of the Camden Society—Crocker's Boswell's Johnson—Edmondson's Heraldry—Gentleman's Magazine, 159 Vols.—Grose's Antiquarian Repertory—Grainger's Biographical History of England—Grose's Antiquities—Sir R. C. Hoare's Modern and Ancient Wills—Johnson and Stevens' Shakespeare—Lysons's Environs of London—Transactions of the Linnean Society—Lowndes's Biographical Manual—Lodge's Portraits—India Paper—Massinger's Plays—Nicholls' Literary Anecdotes—Roscoe's Pope—Pettigrew's Bibliotheca Sussaniensis—Pepys's Memoirs—Rader's Martialis—Todd's Johnson's Dictionary—Walpole's Anecdotes of Painting in England—Watts' Bibliotheca Britannica—Yarrell's British Birds, &c., &c., &c.—Drawing-room, Classical, Poetical, Historical, and Periodical Works.

May be viewed one day prior. Catalogues to be had seven days previously at Mr. Lahee's (only) Offices, No. 65, New Bond Street.

N.B. The LEASE of the above will be SOLD by AUCTION, on the PREMISES, on SATURDAY the 19th, at One for Two o'clock.

Medical Assistant. Wanted imme-

diately, a Gentleman of good moral character, competent to the routine of Country practice. He must be qualified, and if desirous of a permanent engagement would be preferred. Salary £80. Apply to Messrs. GALT, HARRIS, WARD, and OLDFIELD, Wholesale Druggists, Bouvierie Street, Fleet Street.

ASSOCIATION MEDICAL JOURNAL.

LONDON: FRIDAY EVENING, MARCH 11, 1853.

NEW SERIES.

THE GROWING ABUSES OF HOSPITALS AND DISPENSARIES.

IN a recent number (Jan. 28), we directed attention to the manifest and growing evils of the present hospital and dispensary system, more particularly to those which arise from abuses in the administration of the out-patient department. We have reason to know that, in various localities, our remarks have produced the desired impression, and are beginning to be productive of good. We are, therefore, encouraged to return to the subject. The abuses connected with hospitals and dispensaries cannot, however, be remedied by the pen of an editor: they must be *practically dealt with, in every part of the metropolis and of the provinces, by those who are sufferers from the present system.* A number of judicious efforts, made simultaneously, will avail much; and the exertions of a well-conducted and energetic society might ere long be crowned with success.

If the present system of indiscriminate medical relief is to go on increasing as it now does, the profession will no longer retain its present high position. The only competent practitioners in our larger towns will soon be the fortunate few, who are attached as physicians and surgeons to the charitable institutions; while the younger professional aspirant will find that he is utterly excluded from the field, as those patients to whom he very naturally would have looked as the founders of his success, have become the recipients of the gratuitous advice and medicines of a public charity. The fault lies not in the medical officers, but in the system; for how is it possible, in a large town or city, the centre perhaps of a populous manufacturing or agricultural district, for the medical officer to detect persons who are able to pay? The task would be impossible; and the attempt would be most invidious. It is the system itself which is in fault. The out-patients' rooms require a vigilant supervision; and no person should be admitted to the benefit of a medical charity, either as an in-patient or out-patient, who does not bring a certificate from a known subscriber, a clergyman, or a specially authorised inspector, of inability to pay for medical attendance. The system adopted by the "Destitute Sick Society of Edinburgh", is well deserving of imitation. The town is divided into districts, and each district has its own inspector, whose duty it is to make an inquiry into the circumstances of every case; and, after some experience, this duty is not found to be so difficult as at first it may appear.

The number of those who resort to hospitals and dispensaries is incredible, when we consider the population of the places in which they are situated. Let us take an example. In our number for February 11th, we gave a short report of the proceedings at the annual meeting of the "Bath United Hospital", from which it appeared that 13,976 patients had been under treatment during the year 1852. Now, Bath itself contains a population of 54,240, to which if we add 10,000 for the population of the villages in its immediate neighbourhood, we shall find that one person in every four was supplied with gratuitous advice and medicine at one

only of its medical charities! But there are no fewer than seven other general and special dispensaries in Bath, enumerated in the medical directories.* Bath only affords a specimen of that which is going on in every town and city. If our fellow-associates will assist us by collecting the materials, we shall be glad to publish well digested returns from the principal towns of England and Scotland—more ample, if possible, but upon the same plan as that which we have now selected as an illustration.

The medical profession is at this moment, we aver, victimised and cheated by a "charitable public". Charity begins at home; and we are but defending the rights of our own body, and protecting the public against themselves, by lifting up our voices against a system which, if it be not suppressed, must in a very few years destroy the profession, by limiting the recipients of its emoluments to a lucky minority. Let us then maintain the just rights of our profession, let us pursue a straightforward, fearless, and honest course, and, in every locality where the evil is spreading, let the whole of the resident practitioners remonstrate with the governors of hospitals and dispensaries against the heavy evils which they are inflicting under the guise of philanthropy;—*first*, upon mechanics and minor tradesmen, by destroying in the bud the growth of providence, and inducing habits of extravagance in place of cherishing frugality; and *secondly*, upon the profession, by despoiling the many, without enriching the few. And let us diligently keep the subject before the public by means of the London and provincial press.

If hospital managers persist, in spite of all remonstrances, in the present indiscriminate system of relief, let them remunerate their medical officers; and let every hospital and dispensary staff claim this remuneration. The eager canvassing for honorary medical appointments tends to lower the proper value of our services to the public: and let it never be forgotten that the physician or surgeon who cringes to the governors of an hospital, not only demeans himself, but at the same time robs and dishonours his profession.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY, AND ITS NON-REPUDIATION OF HOMŒOPATHY.

WE find by numerous letters which we have received from the country, that the provincial physicians and surgeons were not generally prepared for an announcement incidentally made by us last week—to the effect, that certain homœopathic gentlemen, avowed seceders from the ranks of legitimate medicine, were still allowed to remain on the list of Fellows of the Royal Medical and Chirurgical Society. We are anxious therefore to state, on behalf of the profession in the metropolis, that the Society has never yet had an opportunity of deliberating upon this most anomalous

* Vide p. 650 of the *London and Provincial Medical Directory* for 1853; and p. 516 of the *British Medical Directory* for 1855.

lous and painful fact; and that the whole responsibility lies with the Council of allowing the institution which they govern, to stand alone among the other medical societies of the kingdom, in not protesting against the puerilities of homœopathy; and in neither ejecting nor censuring colleagues for openly engaging in this and other forms of practice, which are alike opposed to all medical experience and sound professional ethics. There is every reason to believe, that were the Royal Medical and Chirurgical Society to be allowed by the Council to discuss the subject, an opinion would be declared similar to that which was adopted almost unanimously by the sister society of Edinburgh, and which the Provincial Medical and Surgical Association adopted at the Brighton meeting without one dissenting voice, as absolutely essential to the maintenance of its honour and respectability. Whenever a Council shall be freely chosen by the Fellows, then, we venture to affirm, will the Society take rank with kindred institutions, as a repudiator of homœopathy. The Society is under the influence of general professional opinion; but the Council, from its exclusive, and we may say, self-elective character, cannot easily be benefited by this healthful agency; and hence (to repeat the burden of the remarks which we made last week), it is essential for the peace, prosperity, and internal discipline of the Society, that in accordance with the letter and spirit of the charter, the nomination and election of the executive shall be made by the Fellows; and farther, that the majority of the Fellows shall be able, without the intervention of an obstructive barrier, to deliberate upon any subject which concerns its reputation. This, however, can never be brought about, so long as it continues to be painfully felt by many gentlemen when admitted to the Fellowship, that integrity, professional honour, and the highest amount of scientific labours are not in themselves sufficient passports to promotion; and that a preference is given at the Council Board to those who belong to certain colleges and even to certain hospitals. This distressing statement is not a new one; and we regret to add that it admits of ample historical proof.

Nothing can more forcibly illustrate the impropriety of allowing a fractional body, deliberating with closed doors, and regulated by arbitrary unwritten rules, to exclude from nomination those who, from seniority on the list of Fellows, and blameless character, are entitled to be presented for election, than a circumstance which has transpired since the date of our last publication. It appears that the President spoke from erroneous information, when he stated his belief "that Dr. Balfour was a Fellow of the College of Surgeons of England, and was in a different position from Dr. Murphy, who did not belong to a London College". Dr. Balfour is not a Fellow of any Royal College of Surgeons or of Physicians, so far as we can discover; and that he is not a Fellow of the College of Surgeons of England, is satisfactorily established by the following official letter from Mr. Balfour, the Secretary of that College, which has been forwarded to us for publication.

" College of Surgeons, March 2nd, 1853.

" Sir,—In reply to your inquiry, I have to acquaint you that Mr. Thomas Graham Balfour, of the Royal Military Asylum, Chelsea, is not a Member or Fellow of this College.

" I am, Sir, your most obedient servant,

" EDM. BELFOUR."

The remark of the President, taken in connexion with this proof of its inaccuracy, indicates that the undoubted claims of Dr. Balfour would have been ignored by the

Council, had it been known to them that he had no English title; and it is thus made to appear to the profession, that a Fellow worthy of honour has only been honoured by accident!

CHEMISTRY, AND THE CLAIMS WHICH IT HAS UPON OUR ATTENTION.

In the summaries of the progress of Chemical Science, which from time to time we shall lay before our readers, our objects will be; firstly, to notice, and where desirable, to criticize whatever discoveries are made, or theories are broached in this branch of Natural Philosophy when bearing upon the ordinary pursuits of the medical practitioner; secondly, to sketch in rough outline the more recondite researches of those students of nature who have devoted themselves to the investigation of the difficult problems involved in the study of physiological and pathological chemistry, with animal electricity and its cognate subjects; and also, whenever the subject is of more than ordinary interest, to notice the discoveries made in those departments of chemical and electrical science not directly connected with medicine.

We have deemed it advisable to classify, and bring together under distinct heads whatever has been discovered or propounded in medical chemistry during the last few months of sufficient importance to merit attention; and we have studied to set forth a systematized account of the discoveries and observations lately made by many experimenters on special and individual subjects, somewhat in the manner of a report on each subject, and to treat of these in orderly rotation, as our space will allow, rather than to seize upon and notice forthwith the latest discoveries merely because they happen to be the latest. Our purpose is, not only to bring under the notice of our fellow-associates the discoveries made in a given subject in connexion with each other; but also to furnish them with a condensed collection of facts on each subject which may hereafter be useful to them for reference, and save them the annoyance of hunting through many numbers to discover the sought-for object.

In our notices involving theoretical disquisitions, we shall strive to avoid, whenever possible, the employment of very novel chemical terms: and when the employment of any well known word will not convey the desired idea, we shall add whatever explanation may appear desirable for the information of readers unversed in modern chemistry, even at the risk of laying ourselves open to the charge of tediousness from those whose acquirements have kept pace with the progress of the science.

NO TRUE BILL AGAINST MR. HICKS FOR MANSLAUGHTER.

WHILE we rejoice that Mr. Hicks has at last obtained justice, we regret that no punishment can be inflicted upon his relentless accusers. The proceedings at the Bedford Lent Assizes are reported in another page, where enough appears to exhibit the malignancy of the prosecution; but we are sorry that the case did not go forward to the proof, as we learn from a correspondent that there was no evidence to show that the diagnosis made by Mr. Hicks during the life of the patient, was more inaccurate than that which

was formed after death by the surgeons who made the *post mortem* examination. From the great demands upon our space, we regret that at present we cannot print the letter to which we refer.

After some very appropriate remarks by the Lord Chief Baron (Sir F. Pollock), the Grand Jury returned—"No TRUE BILL AGAINST MR. HICKS FOR MANSLAUGHTER".

UNIVERSITY REPRESENTATION IN PARLIAMENT.

THE Parliamentary Representation of Universities is a question entirely distinct from that of the parliamentary representation of the medical profession; and we are inclined to think that the commingling of the two in public discussions is likely very materially to injure both causes. The representation of universities ought to be advocated with a view to secure the equal representation of everything that is in them—of literature and science in general, and not of medicine in particular; and, on the other hand, the representation of the medical profession ought, if it be agitated for at all, to be candidly espoused upon its own special merits. The chance of medicine, or even of London medicine being represented in Parliament by the University of London, is visionary in the extreme; and if indeed such an idea had any plausibility, we might ere now have heard it urged as a valid objection to the enfranchisement of that institution. The just claim to representation set forth by the University of London is very much weakened, in place of being in any degree strengthened, by an exaggeration of the probable influence in elections of its medical element: and to aim at medical representation, by swallowing up university representation, is only to obstruct the march of the cause of the universities, without in the least advancing our own.

We regret very much that an agitation for the parliamentary representation of the Scottish universities does not proceed *pari passu* with that which is at present so vigorously carried on by the graduates of the University of London on behalf of their Alma Mater. The universities of Scotland educate upwards of three thousand five hundred men for the higher walks of literature and science, and for the literary and scientific professions; and it is very clear, that if the Metropolitan University has a right to be represented in Parliament, the Scottish universities have a stronger claim. As the claims of both, however, though of a similar character, are in no degree antagonistic, we advise cooperation, feeling convinced that in any parliamentary reform which involves an appreciable change in the constitution of the House of Commons, the united efforts of the unrepresented graduates could not fail to obtain two members for London and more than two for Scotland, while we are equally sure that nothing will be given to the one which is withheld from the other.

The objection, that Scottish graduates have nothing to say in the government of their universities, appears to us to be wholly irrelevant. It was all very well, and very natural, for Mr. Disraeli to make a handle of such a crotchet, because a minister of the crown requires to be constantly looking out for objections wherewith to stem the pressure of parties clamouring for favours; but it is a very odd thing for an unfettered friend of university representation to attach the slightest value to the objection.

The following appears to be the true state of the question.

Is it desirable that great Universities should have their interests represented in Parliament, in common with those of other important bodies in the state? Is it desirable that the science, the literature, and the education of a civilized country should be represented? If both of these questions be answered in the affirmative—and an affirmative answer will undoubtedly be given by the great mass of the educated classes in the British dominions—then, in what better way can these objects be secured, than by means of representatives, chosen by individuals who have been so long and so thoroughly educated at the Universities, as to have carried off literary or scientific honours? And what does it signify to the interests of the country, or of the Universities, or of literature and science, whether such a constituency—provided it be large enough—have or have not a word or two to say in University Government? It might, as Dr. SNOW BECK suggests, be a very proper thing to incorporate the graduates of the Scottish Universities, and the graduates of the University of London, with their respective universities, bestowing upon them at the same time certain rights and privileges; but we cannot see the slightest reason why the want of this incorporation should either prevent or delay the enfranchising of the graduates of the unrepresented universities.

ORIGINAL COMMUNICATIONS.

ILLUSTRATIONS OF DISEASES OF THE HEART AND AORTA.

By R. HUTCHINSON POWELL, M.D.

THE following cases, hitherto mostly unpublished, of cardiac and aneurismal diseases, will serve as types of those affections, and afford an opportunity of glancing at recent views regarding their physiological and pathological relations and their treatment. The narratives are, for the most part, condensed from the minutes of statements made by the relators, with a view to discussion; and, therefore, are not so full as they might have been if designed for publication. With the responsibility attached to the commentaries I am alone chargeable.

I. ILLUSTRATIONS OF CARDIAC DISEASE.

CASE I. HYPERTROPHY OF THE LEFT VENTRICLE WITH DISEASED AORTIC VALVES. (Related by Dr. Theophilus Thompson.) The subject, a man aged 50 years, had been a pedestrian, and his disease was attributable to violent exertion. He had a well marked cardiac murmur. After death, the left ventricle was found to be very much enlarged, as were also the aortic valves, which were opaque and rigid, their borders being relaxed and admitting of retroversion. The aorta at its origin was enlarged and ossified. An aneurismal tumour, of the size of a lemon, was found in the coeliac axis.

This case is a very simple instance of the injurious effect upon the cardiac apparatus, consequent on over-exertion and mental excitement. All the conditions for the production of *bruit* were present; the stream of blood was thrown into eddies by the rigid valves interfering with its free exit from the ventricles; irregular and comparatively slow vibrations were then set up in the vascular wall, thus producing the sonorous phenomenon termed *bruit*. This morbid sound becomes a thrill when perceived through the sense of touch, and requires the great vessels or heart to be in contact with the thoracic parietes for its detection. Death results in such cases as the above, from the heart being overtasked. The valves normally support the column of blood after ventricular contraction, and so give the heart rest; but in these cases, the ventricles being compelled to

sustain the pressure of regurgitant blood, distension and enlargement ensue. The arteries become tortuous from loss of elasticity, and the relation shown by Volkmann to exist in health between the lateral and longitudinal distensibility no longer obtains. The cardiac bruit is propagated along the larger arteries, and becomes so modified and even intensified, as to suggest a local or independent origin. Professor Kiwisch, however, gives very convincing data under this head, which go to prove that, in order to effect the requisite tension for producing sound in an arterial tube, the fluid pressure must be very great, such as never exists in patency of the aorta. The principles of treatment involve the maintenance of the compensatory enlargement and power of the heart. Digitalis and other sedatives are either non-admissible, or but sparingly to be resorted to, as more blood recoils into the ventricles during their slow contraction, than during their rapid action. An issue should be inserted; and if plethora arise, small venesections are to be employed. The indications being to keep the blood diminished in quantity but rich in quality, the muscular system being thus duly supported, no slops or malt liquor should be taken. Exacerbations of slow inflammatory action leading to atheromatous deposit in the aorta, and marked by paroxysms of anginous symptoms (dyspnoea, cardiac pain, palpitation, and sense of impending death), should be met by local bleeding, counterirritation, and a mild mercurial course.

CASE II. DILATATION OF THE HEART, IN CONNEXION WITH NARROWING OF THE AORTA. (Dr. T. Thompson.) The case was that of a young woman, of slender conformation, suffering from palpitation of long date, which latterly had been sufficient to raise the bed-clothes, but with almost imperceptible pulse at the wrist. The apex of the heart beat between the sixth and seventh ribs, about an inch to the left of the line of the nipple, its position rarely changing with change of posture. She had occasionally suffered from rheumatism. Loud and extensive systolic bellows-murmur was audible in the situation of the apex, and in the dorsal region. The case was treated with aperients, calomel, opium and digitalis. The apex of the heart returned to its normal site, and the pulse fell to 80, and became nearly regular, contemporaneously with the production of slight ptyalism; the bruit, however, still persisted. Narcotics were prescribed, but the case terminated fatally six weeks after coming under notice.

A *post mortem* examination showed the left auricle to be distended to the bulk of a cricket-ball; the mitral valve, though slightly thickened, was not contracted, and was partly competent to its function. The left ventricle exceeded its average proportion, from valves to apex, by one inch; its walls were but slightly thickened. The normal measurements (Bisot's) being three inches in length, and six lines in thickness, the right ventricle deviated but little from the usual size: it was three inches two lines, instead of three inches, in length, and two and a-half lines in thickness. The calibre of the arch of the aorta was less by one inch and some lines than the average (two inches seven lines); the aortic valves and the lungs were healthy. Slight regurgitant mitral disease, from relative insufficiency of the mitral valve, probably existed in this case. The situation of the apex was accounted for by the turgescence of the ventricle arising from endocarditis. The left auricle being thus intermediate between two blood-currents of abnormal amount, became dilated; the left ventricle escaping in great part from the effects of the aortic contraction—the most prominent feature in the case—by transferring the *onus* of the circulation to the auricle, with its relatively inadequate valvular protection.

This case well contrasts with the preceding; the indications of treatment being nearly reversed in obstructive ventriculo-arterial disease. The objects in view in such cases are to arrest and remove the effects of inflammation of the internal cardiac coat, and by sedatives, as digitalis, to cause the heart to act slowly; so prolonging the intervals of contraction, as to allow of the arrival and trans-

mission of a sufficient amount of blood. The rate of the circulation should be approximated to that of reptiles, who possess but small valvular apertures, and have but from twenty-five to thirty beats of the heart per minute. In this case, the left auricle compensated for the insufficiency of its valves; and the special effects of obstruction were in part shared with the corresponding ventricle. The physical signs, symptoms, and related structural changes at the aortic opening, characterizing such disease in the walls of each compartment, were unequally distributed, and consequently not clearly referrible exclusively to either chamber of the left side of the heart. The consecutive symptoms occurring in mitral disease were here anticipated by early dissolution, probably hastened by the feeble constitutional resistance of the patient.

CASE III. HYPERTROPHY OF THE HEART, ASSOCIATED WITH GRANULAR DISEASE OF THE KIDNEYS: DEATH FROM APOPLEXY. The subject was a female, aged 25, a laundress. She had had bronchitis with hæmoptysis, for two months previous to coming under notice. Her symptoms were then chiefly pectoral; and five days after admission, she was sleepless from cough. On the sixth day, one eye became amaurotic, and on the eleventh day she had an attack of apoplexy; on the fourteenth day she sank without convulsion or febrile disturbance. Before death, the woman passed her urine frequently, and in small quantity; œdema of the extremities was also present. The treatment embraced cupping, mercurials, tartar emetic, digitalis, camphor, henbane, etc.

A *post mortem* examination showed the convolutions of the brain to be flattened, the cerebral substance being normal in all respects, except in its weight, which was three pounds and a half avoirdupois. The cerebral ventricles were small and as if compressed. The air-tubes were injected, the right lung being congested; there was no tubercular or pleuritic deposit. The heart weighed twenty-one ounces; the left ventricle being the chief seat of hypertrophy. The mitral valve was free from disease; the pericardium exhibited slight traces of incipient inflammation. The liver weighed three pounds and a half, the spleen seven ounces and a half, and the stomach six ounces and three-quarters. The right kidney weighed five ounces, and was less diseased than the left, which was atrophied, and much disorganized, weighing only two ounces and a quarter.

In this case, the renal disease probably existed prior to the cardiac enlargement, which, together with hypertrophy of the brain and of other organs, was a consequence of imperfect depuration of the blood, and interrupted circulation in the blood-vessels and capillaries. Secondary inflammatory disease in the serous membranes is, moreover, peculiarly liable to occur in such cases. The woman's occupation rendered her very liable to defective or checked cutaneous exhalation, and consequent congestive disease of internal organs. The kidneys were manifestly exposed to strain and irritation, from the posture which such occupation requires. The remote cause, however, was most likely a constitutional vice of distant origin, and of slow progress.

CASE IV. ANGINA PECTORIS, WITH OBLITERATION OF THE CORONARY ARTERY, ETC. (Mr. A. Anderson.) A female, aged 32, in good condition and otherwise healthy, had been for seven years subject to violent fits of palpitation, neither preceded by nor attended with rheumatism. Latterly she had suffered repeated attacks of angina pectoris, and eventually died in a paroxysm.

On *post mortem* inspection, a reddened spot an inch and a half square was observed over the pericardial coat of the sinus of the aorta; fibrinous flakes extended across to the opposite wall of the pericardial sac. The aorta was somewhat dilated, and its internal coat for many inches was covered with atheromatous deposit, which also quite filled up the right coronary artery, the left being obliterated in like manner at the origin. The aortic valves were enlarged, and thickened at their free edge, but were apparently competent to their function. The left ventricle was much enlarged, and red. The right ventricle and auricle were greatly

diminished in size, and attenuated. The coats of the coronary vessels were normal, but the right coronary artery was contracted, and contained a coagulum. Obstruction had existed probably for a lengthened period, and induced the atrophied state of the right cardiac chambers, in conjunction with the adaptation ensuing on enlargement of the left cavities.

This case indicates the close causative connexion existing between aortitis and its sequents, atheromatous or fibrinous deposits, the progressive stages of disease being shadowed forth. The primary aberration probably arose from deranged nutrition, which further resulted in slow inflammatory action in the subserous tissue of the vessel, leading to effusion. Angina pectoris is also frequently associated with diseased cardiac valves or orifices, ossification of the coronary arteries, structural alteration in the muscular walls, or other change in the heart; this disease, however, is not necessarily connected with organic change, but is rather the result of disorder of the nerves concerned in cardiac innervation, from mechanical compression or other agency interfering with this function.

CASE V. SLIGHT HYPERTROPHY OF THE HEART, ASSOCIATED WITH FIBROUS TRANSFORMATION OF ITS TISSUE, AND WITH GRANULAR DEPOSIT IN THE LIVER AND SPLEEN, ARISING FROM MALARIA AND CHANGE TO A COLD CLIMATE. (Dr. James Bird.) The subject, a military gentleman, aged 50, long resident in a malarious district of India, returned to England six months before coming under notice. He had been occasionally troubled with diarrhoea, ague, and loss of flesh. He was of spare conformation and nervous temperament, taking much exercise, and enjoying tolerable health while abroad, with the above-mentioned exceptions. He had latterly resided in Lincolnshire; and, on his return to town shortly after, was attacked with muscular pain in various parts of the body, which was neuralgic in character in the inferior extremities. The pulse was 110, irritable, and jerking; the urine was scanty and high coloured; the tongue white; the skin cool; the bowels were moved by laxatives. The symptoms at first increased in severity, and were accompanied with a harsh systolic endocardial murmur, with feeble cardiac impulse. The præcordial dulness was natural. There were slight crepitation and cough, and tenderness along the cervical and dorsal vertebræ, with pain extending to the arms. The urine was acid, of sp. grav. 1034, with lithic deposit on cooling. The patient suffered from attacks of ague, and his pulse in a few days became feeble and intermittent, with anxiety, œdematous præcordia, and coarse respiration. The muscular pains increased in severity, the urine becoming nearly solid from crystals of nitrate of urea, on the addition of nitric acid after boiling. The patient subsequently got relief from some of his symptoms, the endocardial murmur still persisting; but he was troubled with oppression of the chest almost amounting to angina pectoris, with intercostal pain extending to the lumbar region. Three weeks after first coming under notice, he suddenly died in a syncopal fit.

On *post mortem* examination, the pericardium was found vascular, with partial fibrinous exudation. The heart was small, its apex extending to the lower edge of the sixth left rib. The left ventricle was much dilated, its section exhibiting interspersed fawn-coloured deposit, extending to the chordæ tendinæ. Under the microscope, fatty degeneration was shown. The mitral valve was affected with slight marginal thickening. The lungs were emphysematous and congested; the left adhered to the costal pleura from old adhesions; some serum was contained in the left pleural cavity. The liver was finely granulated, and nutmeg-coloured; its left lobe was softened. The spleen was of twice its normal size, and broken up, with buff-coloured patches interspersed. The kidneys were congested, but not otherwise altered. In this case, a blood-lesion probably existed, which became localised from hyperæmia, the effect of cold, and thus led to fibrinous deposition (determined under the microscope), terminating in death.

REMARKS. The preceding cases, as well as those which will

follow, serve to illustrate the paramount importance of taking into account the relation which the contained fluid bears to the circulatory and other apparatus of the organism, in striving to estimate the part played by each in the evolution of disease. That the *fons et origo mali* was the presence of abnormal elements in the blood, together with disturbed nutritive equilibrium, cannot be reasonably questioned. Whence, then, arose this deterioration, or aberration from the normal standard? I shall here quote some remarks made by myself some years ago (*Provincial Medical and Surgical Journal*, vol. for 1846, p. 464), which, I think, are apposite to the solution of this point:—"It may be questioned if our increased attention to physical diagnosis at the present day be not, in some measure, pursued with a too exclusive bias, to the neglect or inadequate appreciation of those subtle elements of disease, collected from a more comprehensive view of the animal economy. Reaction ever leads to erroneous conclusions, if carried beyond its legitimate boundary. . . . If any physical constituent of the organism deserve to be considered *alive*, the blood may well be deemed so; whether viewed in relation with the logical or chronological order of its appearance; pervading all structures, making disease palpable, and eliciting nervous power in support of the nervous functions. The relation which the iron of the red blood-disks holds to the inspired air, places it second in importance only to the oxygen with which it is connected in the circulating fluid, and at once suggests one obvious mode of restoring the blood to its normal standard; thereby again contributing to place the organs severally in that harmonious relation through which health is maintained. . . . When the blood has become impoverished, the heart's texture attenuated, with manifest general debility, my observation would decidedly lead to the administration of chalybeates: viz., in cardiac palpitation, in conjunction with atonic dyspepsia, uterine derangements, hysterical or other nervous maladies; and when manifested in spasmodic individuals of lymphatic or nervous temperament, and relaxed habit; in disposition to syncope, with much præcordial anxiety, attributable to deficient nervous energy, from a depressed condition of the nervous system, in which the heart participates in common with other parts, or referrible to impoverished blood, etc.; in angina pectoris, when apparently unconnected with structural alteration, or, if thus associated, partaking of a passive character. Chalybeates are also indicated in structural disease of the heart, in passive dilatation, with normal or attenuated parietes, or with predominance of dilatation over hypertrophy, if this exist (more immediately indicated by quick and clear sounds); consecutive dropsical affections, with leaden, pallid, or tumid countenance; paroxysms of orthopnoea or syncope, and copious expectoration. . . . Of two evils, I am disposed to consider mechanical (valvular or other) lesion, of less moment than direct loss of power in the muscular walls of the heart, whence more immediately proceeds prostration of the system generally. Indeed, it is peculiarly significant to observe how individuals cling to life, whose heart may have undergone extensive and irreparable injury, provided the impoverished blood admit of reconstruction, and the general powers be duly maintained. In no department of therapeutics is there greater occasion for sound physiological views of the animal economy, as a whole, than in cardiac affections, in which, moreover, the nicest discrimination may be requisite to decide where the lowering system must be abandoned, and tonic treatment had recourse to. I believe the former plan has not seldom been productive of fatal consequences, especially in cachectic habits. . . . The intimate relation obtaining between the circulating and nervous systems, at once serves to denote the mode of production of neuralgic affections of the heart, and to indicate the suitable treatment, when disorder co-exists in either or both. . . . The influence of malaria in producing neuralgic disorders, rheumatism, and associated cardiac disease, by originating a deteriorated condition of the blood, and a depraved habit, offers a wide and most interesting field for investigation."

With reference to the condition of the blood giving rise

to, or accompanying, certain cardiac or aneurismal diseases, it may be considered as originating in an imperfect elaboration of the blood-plasma, or other reparative constituent; the constitutional vice in the organs engaged being related to defective assimilation and renovation, rather than to change connected with the process of decay, the result of decomposition and rearrangement of the elementary constituents, independent of any further addition *ab extra*. The term "degeneration" as now used, appears to imply but one purely chemical source of textural change, but may with equal (if not greater) probability be referred to inadequate renewal or reproduction of tissue, arising out of abnormal conditions of cell-growth, and defective formative power in the in-coming nutritive pabulum. Chemical authorities are at issue as to whether or not azotised and non-azotised blood-constituents are respectively convertible; the animal organism being, however, pre-eminently a reducing apparatus. Now, although the myoline of muscular fibre becomes replaced by oily particles, in fatty metamorphosis, we have hereby no positive (only analogical or presumptive) proof of a conversion of the former into the latter having taken place. An excess of adipose material, favourable to fatty deposition, may obtain from its *decreased consumption*, through inaction of the liver, lungs, skin, and kidneys. Again, excess of oily constituents may result from *conversion* of the more animalised components of the tissues, in their removal from the system by the agency of the liver, as stated by M. Bernard. This, however, is effected by glandular activity, and bears little analogy to that change, which ensues in organic matter removed out of the sphere of action of the living organism. In the latter case, the play of chemical affinities, operative in the conversion of fibre into fat or adipocere, would seem to require the presence and co-operation of air and moisture. This conversion does not ensue when, as in the process of preserving meat, oxygenation is prevented by the exclusion of atmospheric air; the changed condition of the fibrous and other tissues by the cooking process not of itself precluding, though retarding decomposition. Fatty transformation may be said to take place, for the most part, under very different conditions, too numerous to specify here, but sufficiently obvious in the body during life. Blood-fibrin differs from the fibrinous basis of muscle, according to Strecker, in being more highly azotised; in its behaviour with a dilute acidulous solution, in which it gelatinises, but does not dissolve; and in not being dissolved by an excess of alkaline precipitant; the reverse holding with reference to the fibrin of muscle, which approximates to albumen in composition and chemical relations. The fibrin of blood would appear to be the nutritive constituent of the simple fibrous membranes, such as the elastic arterial tissue, pericardium, etc.; its amount in the blood being adequate to this, but not sufficient for the growth and repair of the muscular system; while the large proportion which the albuminous constituent of the blood bears to the other ingredients, seems to denote it to be the agent for the fulfilment of the latter office. Now, if we consider the blood to be defective in the amount or elaboration of the albuminous constituent, the other ingredients said by Heller to be required in the process of healthy cellular nutrition—the calcareous salts and oily pabulum—being either normal or aberrant, we may account for the falling away in the cardiac and vascular tissues, simply as the result of mal-assimilation—to employ a term long in use, and conveniently expressive of a recondit operation.*

* Professor Schultze has lately determined some points of interest in connexion with this subject.

1. Fatty matter is conveyed into the system as fat, *ab extra*, in drops or fine divisions.

2. It is produced by conversion of non-azotised or non-fatty food.

3. It is produced from nitrogenous food, as in diabetes.

4. It is produced from the tissues only in disease.

Fat in excess leads to disease. It is increased during the resolution of pneumonic exudation. It may be present in considerable amount in the blood, or is detectable by the microscope.

In opposition to Virchow and Reinhardt, who assert that every kind of cell can undergo fatty metamorphosis, Schultze affirms that this is connected with the quantity of material, and is only an index of a previously commenced change, depending upon some peculiarity in the nature and time of origin of

It would be interesting to determine whether the salts of lime and the organic acids are defective in, or absent from the urine of those in whom deposits of cholesterine and calcareous matter take place in the valves, on the surface, or in the walls of the heart, as well as throughout the circulatory apparatus. We want precise information on these most important points. In the meantime, we can trace to some extent the disjointed and remote links in this morbid chain: witness the association and interdependence between malaria, rheumatism, abnormal deposits in the tissues, and defective nutrition, secretion, and excretion, through biliary, splenic, and renal *remora*, as evinced in some of the preceding illustrations. The centre of the circulatory apparatus of course bears, in many cases, the greatest strain on its function; and, in consequence of its primary importance to the organism, its disease more immediately leads to a fatal issue. The tendency to this result may be often masked till death take place; and it may be doubted whether we possess any certain or even probable indication of the imminence of this event, those premonitory symptoms assigned as diagnostic being often absent up to the last moment of life, and the *post mortem* examination giving the first demonstration of the existence of disease. The cases of the late Dr. Chalmers and of other eminent men are memorable instances in point.

With respect to fibrinous or albuminoid deposits in the parietes of the heart or blood-vessels, or on their lining membrane, there are many facts, derivable from humoral pathology, which would indicate such deposits to be of not-unfrequent occurrence, and not unlikely to materially interfere with the circulatory function. It may be recollected, that the fibrinous constituent of the blood is far from being uniform in its chemical composition, under various morbid phases; and to this deviation, as well as to its varying proportions in the circulating fluid, is referrible occasional structural regression in the tissues. The muscular fibres of the heart and blood-vessels approach blood-fibrin in composition, though not identical with it; and the heart, in common with other involuntary muscles, has little cellular tissue entering into its structure. Those diseases, such as rheumatism, scorbutus, certain forms of chlorosis, etc., in which the amount of fibrin in the blood varies, are not-unfrequently associated with cardiac, aneurismal, or hæmorrhagic affections; these latter diseases being no doubt closely connected with structural deviations in the tissues or lining membrane of the vascular apparatus.

[To be continued.]

ON DISTICHIASIS.

By WHITE COOPER, Esq., F.R.C.S., Senior Surgeon to the North London Eye Infirmary, and Ophthalmic Surgeon to St. Mary's Hospital.

SINCE the publication of my communication on Distichiasis, in the ASSOCIATION JOURNAL of February 18th, my attention has been called to a very able paper by Mr. Wilde, of Dublin, on "the Causes and Treatment of Entropium and Trichiasis",* and I regret that, when writing on the subject, I should have overlooked the following remarks, as they are the result of extensive experience; for, in Ireland, affections of the eyelids appear to be very common among the lower orders. Mr. Wilde says: "The fact of an additional growth of hairs has been denied; and it is asserted that, 'although they issue from the wrong place, and grow

the nucleus. Fat may pre-exist in the cells, as well as arise from the transformation of protein constituents. The evolution of cells into granular (fat-containing) cells is not a retrograde metamorphosis. The vitality of a cell, as of the containing organ, is increased; the fat being plastic.

Ingested fat serves especially for respiration, and occasionally for the nutrition of organs, assisting in cell-formation. Fatty degeneration of organs and adipose metamorphosis of their special tissues cannot be dissociated.

Several of these deductions are irreconcilable with, or militate against, the prevalent doctrine respecting "fatty degeneration", and serve to affirm the views above taken, as regards the mode of production of this abnormal condition.

* Contributions to Ophthalmic Surgery. Part II. Dublin, 1844.

in a wrong direction, they are not new productions, but merely natural cilia, the bulbs of which have been displaced by disease affecting the border of the eyelid; and had I not several preparations in my possession, which show an undoubted additional growth of these hairs, I should be very slow in differing from this, one of the highest living authorities upon ophthalmic surgery. In these cases, however, I not only examined the tarsal margins minutely after their removal, but counted the cilia, and they invariably amounted to more than what occurs in health; although it must be acknowledged that the number varies even in a healthy or natural condition.

"In psorophthalmia, and particularly in tinea palpebrarum, when inflammation attacks the whole margin of the eyelid (especially the upper), and the cutis swells considerably, while small abscesses form round the roots of the individual hairs, and the entire surface in some cases presents a condylomatous appearance, the interspaces between the cilia enlarge from the unhealthy deposit in the part; so that the natural position of these hairs is reversed, being then more divergent where they pierce the skin than at the roots; and they likewise exhibit a bushy, very irregular and distorted appearance, in a well marked triple or quadruple row. Now, although the original disease that produced this state may be speedily removed, still the fibrous deposit along the margin of the lid which altered the relation of these hairs, remains to a certain extent, and keeps up their deformity, or unnatural or distorted position, in whole or in part, so as subsequently to produce the disease called trichiasis, the apex of the line of hairs being then at their roots along the cartilage, and the base at their fine extremities."

The following mode of treating single hairs when inverted, is well worthy of attention:—

"In such cases, placing the horn spatula within the lid, I make an incision with a small knife down to the root of the inverted lash; and, having waited till the hæmorrhage has ceased, I apply a point of nitrate of silver by means of a *porte-caustique* down to the bottom of the wound, and then remove the lash; it seldom fails, but frequently it destroys two or three of the neighbouring cilia."

I avail myself of this opportunity of stating, with reference to Captain T., whose case I described, that the lids close with facility, and the corneæ have become clear; he is able to read with comfort in any amount of light, and much improvement has taken place in his appearance.

19, Berkeley Square, March 5th, 1853.

DISLOCATION BACKWARDS OF THE HEAD OF THE HUMERUS.

By EDWARD JACKSON, M.B.

SIR A. COOPER and Mr. LESTON allude to dislocation backwards of the head of the humerus as an exceedingly rare accident.

Having lately met with a very well marked example, I have thought that it may be useful to the profession to give an account of the peculiarities of the case, and of the manner in which reduction was accomplished.

CASE. The subject was a strong muscular man, aged about 35 years, who had for some years suffered from epilepsy. During one of these attacks, falling suddenly, he sustained a dislocation of his left shoulder.

The following condition of the limb was presented. The arm was removed from the side, but the patient could with considerable effort raise it to a horizontal position. On comparing the two shoulders, there was a greater prominence observable posteriorly on the left side, but not so much so as one would have expected to find in an accident of this kind. There was little, if any, falling down of the head of the humerus, as in dislocation downwards; nor was there so great a projection of the acromion process; yet this was tolerably conspicuous anteriorly at the point of its junction with the clavicle. The head of the bone could

not be felt in the axilla. The tendon of the biceps, arising from the coracoid process of the scapula, together with that of the coraco-brachialis, were felt anteriorly like tense cords stretching from above downwards. But the most remarkable diagnostic sign of this dislocation was a circular depression on the anterior aspect of the joint; and when the fingers were somewhat forcibly pressed into the centre of this depression, the whole circle of the glenoid cavity could be distinctly felt. This at once identified the accident as dislocation backwards.

Reduction was attempted by extension from the upper and lower arm, whilst an effort to replace the bone by rotation outwards was made; but after persisting for a considerable time, and using great force, no movement resulted. Having given up the attempt to reduce by this method, we had recourse to a different plan. The forearm was flexed, whilst slight extension was made at the same time, and the bone simultaneously rotated outwards; and thus, with little effort, the reduction was effected.

It appears that the chief obstacles to reduction in this peculiar dislocation consisted in the violent tension of the tendons of the biceps, coraco-brachialis, and pectoralis major muscles.

Ecclesfield, near Sheffield, Feb. 1853.

BIBLIOGRAPHICAL NOTICES.

SIX LECTURES ON MATERIA MEDICA, and its Relation to the Animal Economy. Delivered before the Royal College of Physicians in 1852. By JOHN SPURGIN, M.D. 8vo., pp. 204. London: 1852.

SOME years ago, an annual course of "*Six Lectures on Materia Medica*" was established by the Royal College of Physicians, for the purpose not only of explaining the sources, preparations, and properties of medicines, but also of unfolding the principles which should be observed in their administration. These principles, of course, are founded upon a much broader basis than mere pharmacy, and indeed can only be deduced from a study of the science of medicine in all its relations, including anatomy and physiology. Dr. SPURGIN proposes, in this course of lectures, "to examine certain principles and laws which the animal economy presents to our observation, and by the operation of which it is constantly preserved and perpetuated". These laws and principles he deduces chiefly from an examination of the nature and constitution of the blood, and the part which it performs in the economy of animal life. The subject of these lectures, therefore, is not (as the title would lead the reader to expect), what is commonly understood by the term *materia medica*; but it is, in fact, the *physiology of the blood, and its connexion with pathology and therapeutics*.

A disquisition on such a subject, from the pen of so accomplished a physician as Dr. Spurgin, cannot but be interesting to the profession; and, as the author's views are in some important points perfectly original, differing essentially indeed from the commonly received opinions, we feel it incumbent upon us to give a short analysis of the contents of the volume.

Dr. Spurgin's theory of the animal economy is based upon the hypothesis, that "the blood, by its universal presence in the system, and in virtue of its being the very origin and source of every part, and thence of the whole bodily fabric, constitutes the very corporeal life and vital principle to which they all refer and are subordinate". By boldly assuming this theory, and investing with a material, though fluid attribute, the vital principle, the author has at once cut the Gordian knot, and banished from the vocabulary of medicine all the vague terms with which former physiologists have endeavoured to express a something which they could not comprehend, nor believe to have a material existence. If Dr. Spurgin's hypothesis be received, the terms *vital principle, vis nervosa, vis medicatrix nature, materies*

vite diffusa, morbid irritability, nervous irritation, and many others, will become obsolete, and the word "blood", with the addition of a suitable adjective when required, will express them all.

The volume contains six lectures. Lecture I is introductory, and describes generally the component parts of the blood, chemical, mechanical, and microscopic. The errors and confusion resulting from an examination of the blood after it has quitted its appropriate vessels, and assumed new properties, are well expounded. The fibrin and albumen, which contain the same elements in the same proportions, the author points out as differing from each other only in this respect, that the latter requires a high temperature for its coagulation, whilst the former will at a low temperature coagulate spontaneously. He then proceeds to show that, in the words of Liebig, "everywhere throughout organised nature, we find the phenomena of life depending upon the presence of albumen; the continuance of life is indissolubly connected with its presence in the blood, that is, in the nutrient fluid"; and that, with regard to the crassamentum, as was remarked by Dr. Bostock, its coagulation is inexplicable upon any common principle of philosophy. After referring to the circumstances which retard or prevent the coagulation of the blood, Dr. Spurgin adds:

"I see no satisfactory reason for following the hitherto beaten track, in order to investigate the properties of the wonderful fluid which performs the most essential part in the animal economy; for, the more I examine its bearings, the more fully I am convinced that this track will lead those who pursue it, in a direction the very opposite to that which can terminate in the satisfaction of the sincere and honest lover of truth." (p. 30.)

Lecture II is devoted to the minute investigation of the globular portion of the blood; and the author shows that a very imperfect knowledge of the subject is to be obtained from chemical analysis only, and that the observations and conclusions of different microscopic observers are very discordant. He traces these contradictions to the examination of the red globules by physiologists after their removal from the circulation; whereas Leeuwenhoek described them as seen by means of the microscope whilst circulating in the living body, and consequently in a more true and natural condition, as well as under more favourable circumstances. Hence, besides other sources of uncertainty incident to microscopical examinations (which the author gives in detail), a new and more important source of fallacy arises from one observer examining *living*, the other *dead* globules. It appears, by the observations of a German author, Dr. Wedemeyer, that "*the streamlets of blood, which consist of a single string of globules, are not red, or even materially coloured, before the microscope, because the globules singly appear yellow, and acquire a red colour only when collected into masses*". And this is confirmed by Haller, Spallanzani, Mascagni, Oesterreicher, and other authors, who all affirm that the apparently colourless vessels which contain the globules, are strictly capillaries, of a yellow rather than a red colour; and that these capillaries, admitting only a single row of globules, appear yellow in consequence of the small amount of colouring matter they contain. It appears, however, doubtful whether the term "colouring matter", however convenient for description, is strictly applicable to the constitution of the blood, seeing that every object owes all its colour to the power which it possesses of modifying the rays of light which fall upon it; and this power in the blood appears to consist in the aggregation of the globules.

In Lecture III, the same subject is continued in detail; and, in the conclusion, some allusion is made to the fluidity of the blood, as one of its leading and most essential properties.

Lecture IV is chiefly occupied in developing this important principle of fluidity. The property is described as existing antecedently to any solid bodily atom, whether denominated cytoblast, germ-cell, fibre, or even capillary vessel.

In Lecture V, another step is taken, and the author adopts the opinion of Boerhaave and other eminent

men, as to the existence of a nervous fluid; and this fluid Dr. Spurgin does not hesitate to identify with the blood itself. He traces its course through the internal carotid and vertebral arteries "to their terminations in and about the cortical, cineritious, or vesicular substance of the brain." We quote his words:—

"Arriving at this region, a condition of vitality, or of animating property, is entered upon; the fluid and the organ are then co-ordinate and co-operative; the activity of the former, and the re-activity of the latter, are to each other exactly as the active pressure of the blood is to the heart, and as the reaction of the heart is to the blood, the effect of which is the circulation of the blood through every part of the body. In like manner, the cortical spherules, or vesicles of the cineritious substance, may be considered as so many little hearts, expanding on the entrance of the blood from the arteries; and when so expanded, they are in a condition to contract, and by this means to forward their animating contents to every point to which the nerves proceed." (p. 148.)

From this physiological theory (for which the author claims no originality, although, with its relative dogma of the humoral pathology, it has been long exploded), Dr. Spurgin proceeds to deduce his pathology of fever and other diseases produced by pestilential vapours, which he believes to gain access to the brain through the medium of the blood alone, and thus to derange its functions, and disorder the whole nervous system. Thus he describes the poison of lead, for instance, as "advancing through the nerves rather than through the capillary vessels, to the muscles affected" by paralysis. He thence derives certain therapeutical conclusions, and in this way brings the subject to bear upon *materia medica*. In the conclusion of his lecture, he thus illustrates the value of his arguments, by a practical application of his views.

"If, then, there is a nervous fluid, we may naturally conclude, that it must be subject to various derangements, which would, in a corresponding degree, affect the brain. And surely these derangements ought to be regarded as capable of cure upon still more philosophic and enlarged principles of treatment than have been yet adopted; upon such, for instance, as would make chemistry minister to the production of gaseous remedies, more likely than either solid or liquid matter to reach the very root of the maladies in question." (pp. 172-3.)

In Lecture VI, the author traces the process of formation of an animal being from, first, a fluid; next, the "manifest initiations, so to speak, of a nervous system; then the beginnings of a vascular system, which follows the composition of a colourless fluid, and precedes the composition of red blood". This order he considers as continued through all the subsequent stages of formation, up to the very completion of the animal being. He next proceeds to examine the anatomy of the heart, as the instrument of the circulation of red blood. He challenges the generally received opinion, that the parietes of the heart are supplied with blood from the coronary arteries. He regards these vessels rather as safety-valves, adapting themselves, by their dilatable structure, and the numerous rugæ or folds on their internal surface, to the fluctuations in quantity to which the blood in the heart is subject: receiving more blood at some times than at others from the cavities of the heart, and returning a quantity adequate, in case of need, to ensure a due provision for its muscular fibres. Thus he believes them to perform, in a limited sense, the double office of arteries and veins, their primary office and anatomical structure being venous; and the fleshy ducts which lead from the crypts of the auricles and ventricles into the muscular substance of the heart, he describes as the *arteries of these veins*. These views are illustrated by anatomical and physiological experiments of a highly interesting nature, and well worthy of study.

It will be perceived by the above very imperfect sketch, that Dr. Spurgin traverses that very extensive ground which has afforded matter of laborious research to Haller, Hunter, and other minds of the highest order; and his object has been, not so much to add new materials, as to give a new form and shape to those already gathered by his illustrious

predecessors. This, to be done satisfactorily, requires a master-mind; and it is not necessary for us to pronounce any opinion as to the degree of success which has attended the effort.

There are, however, one or two points to which we would direct special attention. We will begin with Dr. Spurgin's theory of life. The term life has been applied to an aggregate of phenomena manifesting themselves in succession, for a limited time, in organized bodies. It has been viewed as a principle superadded to organization. Dr. Spurgin maintains, however, that although organization cannot exist without life, life may exist without organization: and further, that *the blood itself is the vital principle, the corporeal life which animates and sustains the whole organism.* Now, by thus identifying the blood with the life, the author lays himself open to the charge of confounding the living thing with the principle of life which animates it; and he admits that his views may, at first sight, appear incongruous and unsatisfactory. But a little reflection will show, that we do not know that life is a principle, we only assume it; and we know not what we mean by the term. We know what the author means by blood, but we cannot form any definite idea of the principle of vitality. It is a mere attempt to express in words a something which we do not understand. There is, however, a difficulty in Dr. Spurgin's language more palpable than this, and, as we think, not so easily disposed of. If blood is life, then blood ceases to be blood when and where life ceases to exist. But Dr. Spurgin himself calls it "blood" after it has escaped from the blood-vessels, and contrasts it, in this condition, with "living blood". We believe, however, that this objection does not militate so much against the author's views, as against certain hyperbolical forms of expression with which he has unhappily encumbered an otherwise lucid, and, indeed, elegant disquisition. If he had simply described the blood as that which first receives and then transmits and sustains life, he would, we think, have conveyed his own idea in less questionable language. Indeed, in the third lecture, his views are expressed in very different terms:—"By virtue of the blood the body lives, and by living acts; in other words, the blood imparts to the body the ability to feel and to act." He regards the blood as that which is principal and essential in the animal economy; the structure as that which is instrumental and efficient.

Then, again, he differs from, we believe, all modern physiologists, in claiming for the fluid blood a vitality independent of organization. He says—

"Although the organization without the blood is powerless, we shall find, on the other hand, that without the organization it is not so; for the impregnating fluid, which may be virtually and pre-eminently regarded as blood, has within it an inherent power, forming, as it were, the starting-point of a new creature."

This fluid, however, like the blood itself, cannot be said to be wholly without organization. Its cellular structure is essentially organic, and, in many animal tissues, is permanent throughout the whole life of the individual.

Notwithstanding these slight inaccuracies, the style is, on the whole, clear and simple; the arguments are well sustained, and the conclusions sound and philosophical; and we cannot but congratulate the profession upon the timely appearance of a treatise on a difficult subject, well calculated to direct to some useful purpose the spirit of sceptical inquiry which pervades the minds of many of our younger brethren. The unexampled audacity of modern quackery, the flippancy with which established truths have been challenged, and modern errors exaggerated, however mischievously they may have acted on the popular mind, may have had their influence on the profession in awakening a more searching scrutiny into first principles, and a more diligent examination of the foundations of our medical faith. These lectures are the produce of a sober and well-furnished mind; and while they are quite up to the mark of modern science, they betray none of that restless intolerance of established doctrines, which has unsettled the minds of so many transcendental thinkers and would-be

philosophers. We commend them to the attention of all who are interested in the investigation of the subject of which they treat.

TREATISE ON CORNS, BUNIONS, AND THE INGROWING OF THE TOE-NAIL. By T. J. ASHTON. London: 1853.

THE author divides his work into three parts. The first treats of Corns, the second of Bunions, and the third of Ingrowing of the Toe-nails.

CORNS. Mr. ASHTON says that there are two kinds of corns: the *hard* and the *soft*. The former arises from condensed and thickened cuticle; the latter "is an excessively painful fungous growth from the cutis vera, and occurs between the toes."

The *hard corn* he treats by applying to it the nitrate of silver, or nitric acid, or by paring it off with a scalpel; the latter method he prefers. Chiropodists, he states, have recourse to the practice of applying pieces of thick soft leather spread with adhesive plaster, and having a hole cut in them over the corn. This mode of treatment Mr. Ashton at first objects to, probably from the illegitimate source whence it comes; for he subsequently recommends the same expedient. His plasters, however, are spread on amadou, or a soft felt, like that used for the hammers of pianofortes. Previously to applying the pad, the corn requires to be covered with a piece of thin plaster to prevent the bulging of the integuments through it. This procedure, we believe, is adopted by most chiropodists; and indeed by the majority of those who suffer from, or have to treat corns. When the integument beneath a corn is irritable and painful, Mr. Ashton recommends a plaster composed of alcoholic extract of aconite, and lead plaster; but in what proportions we are left to conjecture.

The *soft corn* is treated by Mr. Ashton by applying to it nitric acid, and removing in a day or two the shrivelled and hardened part with a cataract knife. "Plasters," the author says, "applied over the surface of a soft corn, have not the beneficial effect in retarding their (its) growth, and affording ease, they have in the hard variety; but a small quantity of astringent ointment, applied every morning, will be of great service." The composition of this ointment, however, he does not divulge.

BUNIONS. "It is the popular opinion," the author states, "and I believe the same is also entertained by many of the profession who have not made dissections of the parts concerned, that a bunion consists of an enlargement of the bones, forming what is called the ball of the great toe." Except in complicated cases, we were not aware that this opinion is held by the profession: however, as Mr. Ashton states, the opinion is incorrect.

Mr. Ashton quotes largely from a valuable paper published by Mr. Aston Key, nearly twenty years ago, in Guy's Hospital Reports, to show how bunions arise, and how they are to be treated. In one respect, however, he differs from his author. Mr. Key deprecates the formation of an abscess in a bunion. When it does take place, however, he says "it is better to let nature carry on the operation without interfering with the knife: the abscess is slow in coming to the surface; but the joint beneath is secured; and we often have the satisfaction of finding that, the suppurative process being at an end, the sore heals, and the part loses its former extreme sensibility. I have known gangrene of the foot and death ensue from opening an inflamed and suppurating bunion; and in three cases, exfoliation of the bones, with a most tedious and painful suppuration of the surrounding structures". Not having these fears before his eyes, Mr. Ashton directs "as soon as suppuration in the bunion is fully established, that a free incision be made, so that the suppurating cavity may be thoroughly exposed". The following day he fills the cavity with lint or charpie, "in order to induce destruction of the bursa, and sometimes to accomplish this end it will be necessary to use the nitrate of silver or concentrated nitric acid".

INGROWING OF THE TOE-NAIL. The author prefaces his chapter on this subject, which concludes the work, with a

very meagre account of the structure and growth of the nails, referring his readers "to the various excellent works on anatomy and physiology for further information". He then copies verbatim from other writers (principally Wardrop and Colles,) the description of the causes, and mode of treatment: but we are not presented with any addition to, or improvement upon the practice of these two eminent surgeons. The only original criticism which we have noticed, is an objection to the term "ingrowing of the nail". We are told that, "from the improper nomenclature of the disease, and from want of due reflection on the mode of growth and formation of the nails, many eminent surgeons in their treatment have been induced to practice evulsion of the nail." This severe and painful operation Mr. Ashton does not recommend, and we believe it is seldom necessary; but we can scarcely imagine that such surgeons as Sir Astley Cooper, Liston, and Dupuytren, would have had recourse to it, either from being misled by the misnomer of the disease, or from their ignorance of the growth and formation of the nails.

We are sorry that we cannot speak more favourably of this work. It is the result of a species of book-making which ought to be discouraged. The whole of its practical and useful matter might be comprised in a page of one of the weekly medical journals, and in this form it might have been an acceptable summary of the practice of the best surgeons, in the treatment of these common and troublesome affections. In a work aspiring to be considered as a monograph on any disease or class of diseases, we have a right to expect to find either the elaborated results of the matured experience of the author, or a luminous and critical digest of all that has been written by others on the subject: and, as we have discovered neither in Mr. Ashton's work, we have been disappointed with the result of his labours.

PERISCOPIC REVIEW.

CHEMISTRY.

RECENT PUBLICATIONS.

OF works on Chemistry published in England during the past year, the most important to medical science is the *History of Physiological Chemistry*, by Professor G. H. LEHMANN, issued under the auspices of the Cavendish Society, in the form of a translation by Dr. DAY, the second volume of which is on the point of appearing. The great merit of this book is, that it is an attempt, and in many instances a successful one, to systematize, and reduce into something like order, the heap of materials on zoochemistry accumulated in the numerous scientific journals of Europe, and thus to acquaint the reader with whatever has been effected of a trustworthy character in this department of chemistry up to the end of the year 1849. The subjects are classified in a manner which renders them easy of reference, and so constructed as to separate fact from hypothesis, and hypothesis from fiction. The translator has done his work well. It is of course, as in the study of any science, here requisite to master the exact meaning of the terms employed; when this is done, the rest is easy of comprehension to any man tolerably versed in physiology and chemistry.

On animal electricity, the abstract of DU BOIS REYMOND'S work, by Dr. BENICE JONES, has appeared; but this book has been noticed in a previous number (No. III.), so that it is unnecessary for us to say more of this instructive little work.

THE BLOOD AND ITS DERIVATIVES.

THE observations which have been lately published on this subject have been numerous, and in some cases well deserving of attention. Thus, M. VIRCHOW, in a paper on *Hæmatoidin* and *Bilifulvin*, recalls to our memory the observation of Reichert on the existence of an albuminous body in a crystalline form, which he found in a substance resembling dried blood, probably derived from some extravasated blood which covered the surface of the placenta and the membranes of the nearly mature fetus of a guinea-pig, as well as the adjacent mucous membranes of the uterus; these crystals being tetrahedrons, of a blood-red colour, and seemingly consisting of a protein substance, impregnated with hæmatin. In Reichert's view, the power of cry-

stallization is inherent in the protein substance, whilst the colouring matter is regarded merely as an accidental mechanical mixture. The great similarity of these crystals to hæmatoidin, formerly termed xanthose, attracted M. Virchow's attention to this subject, with which he is familiar, having formerly shown that crystals of hæmatoidin (which, he states, crystallizes both in oblique rhombic prisms and perfect rhombohedrons), may be formed, first, in cells; secondly, in amorphous protein matter; and thirdly, from aggregations of the blood-corpuscles, fusing together without diffusion of the hæmatin, and undergoing change simultaneously; and he concludes that wherever hæmatoidin is being formed, both hæmatin and a protein substance are present; and, consequently, that hæmatoidin is a compound of these two substances. This observer combats Henle's supposition that hæmatoidin is of a fatty nature, but admits that fat has a peculiar attraction for this substance, appearing to favour its formation, by aiding the metamorphosis of the hæmatin. Its crystallographic relations differ from those of both cholesterolin and stearin; it occurs frequently with the former, as in cysts of the thyroid gland, whilst pure stearin has not yet been found in the human body. We shall return to this paper hereafter, in order to describe the researches on the bile-pigment.

Professor LEHMANN also has directed his attention to the crystallization of the albuminous substances, pursuing the track opened by the observation of Dr. Funke, that when the blood of the splenic vein of the horse was gently dried between the object glasses of a microscope, it became converted into a mass of prismatic crystals; a property also possessed by the blood of many fresh-water fish. The vena portæ of the horse yielded similar crystals when examined by M. Lehmann, whilst other observers have procured these crystals from the blood of dogs, both in health and disease, and from the whole of the blood in a case of leucæmia, accompanied with great enlargement of the spleen. When the blood of the guinea-pig, the rat, and the mouse, were subjected to examination, tetrahedral crystals, similar to those observed by Reichert, were obtained; and from that of the squirrel Kunde has procured large six-sided crystals. The blood of birds, of man, of the horse, excepting that derived from the spleen and the vena portæ of the ox, etc., could not be made to yield crystals, in spite of numerous experiments by this observer.

The bursting, or at any rate endosmosis, of the blood-corpuscles being an essential element in the production of these crystals which are formed from their contents, the serum itself never crystallizing, some reagent must be employed to promote this action; for this purpose, water with ether acts most readily. Blood, mixed with this liquid, is placed in a tube, closed at one end with pig's bladder, and at the other with a thin sheet of caoutchouc, and through this latter weak spirit is passed into the blood by endosmosis, until the mixture in the tube begins to grow turbid; the water must now be allowed to evaporate through the membrane, at a temperature a little below 70°, whilst the spirit passes off through the India-rubber, when beautiful crystals will be formed. Sometimes, as when the blood of the guinea-pig is used, these will measure as much as three-quarters of a line in diameter. Blood-clot, or the sediment obtained by washing blood-corpuscles with water, yields the best crystals. When purified by repeated agitation with cold water, to remove adherent envelopes of the corpuscles and other foreign matter, and subsequent solution in water of 104° to 122°, filtration and crystallization, these crystals are found to effloresce rapidly in the air, from loss of combined water, after which they split into horn-like conchoidal fragments. They are acted on by the reagents which affect albuminous matters, coagulate at a temperature from 140° to 160°, and consist, according to Professor Lehmann, of an albuminous substance combined with an inorganic salt, analogous to the compound formed by diabetic sugar with chloride of sodium.

Since the publication of the papers of which the above remarks are an abstract, Dr. MECKEL, at a meeting of the *Geellschaft für Wissenschaftliche Medicin* of Berlin, on September 6th, 1852, made the following communication, which is inserted in the *Deutsche Klinik* of 9th Oct. 1852.

The colouring matter of the blood, or hæmatoglobulin (the true colouring matter, hæmatin, has not yet been procured free from the globulin of the blood-corpuscles), exists in the interior of the corpuscles, between the nucleus and the wall. Under the influence of various gases, it assumes a yellow-red or bluish, an arterial or a venous tint; and this change of colour certainly is not dependent on a change in the form of the corpuscles, as has been assumed by Scherer and Harless.

The red arterial hæmatoglobulin is not crystallizable.

feebly arterialised blood, the hæmatoglobulin crystallises only sufficiently to denote the admixture of venous blood. By the further action of oxygen, there appears to be produced a green colouring matter (hæmatochlorin), which produces the green aspect of carcasses, but which has not yet been separated by art in these cases; but it is found in abundance in the placenta of carnivora. The green matter already examined by Barruel is allied to the green colouring matter of the bile and of leaves: it is soluble in alcohol and ether, but insoluble in water. The mineral acids produce a play of colours; and it is amorphous and uncrystallisable.

The blue venous hæmatoglobulin can be obtained in drops from the blood-corpuscles of frogs and fishes, and be received into a concentrated solution of albumen, like drops of fat, without being dissolved; but it is soluble in water. In the human subject, the venous hæmatoglobulin saturates all the tissues, but is likewise concentrated by living elementary cells in the form of drops, in the same way as deposits of fat, nervous matter, chondrin, or calcareous matter, are found in other cells. Hæmatoglobulin cells of this kind form a part of the so-called blood-corpuscle-containing cells of authors. True blood-corpuscles are never found in true cells; the corpuscles are neither at first enclosed, in cells, nor do they pass into cells already formed, as Virchow assumes. These drops of colouring matter are distinguished from the blood-corpuscles by being of a globular, not discoid form, and by their variable size. In these cells, the hæmatoglobulin becomes changed, at a later period, into hæmatoidin or melanin.

The venous hæmatoglobulin of all vertebrate animals, and of man, whether in health or disease, is crystallisable, as has been pointed out by Budge, Remak, Lehmann, Kunde, etc. (an assertion opposed to Lehmann's remark, as above). Under certain circumstances, the contents of each individual blood-corpuscle in fish, in swine, and in man, form themselves into a crystal, loosely enclosed in a colourless membrane. Numerous needle-shaped crystals are generally seen in blood-corpuscles; and on these frequently depend their indented and shrivelled appearance. After removal of the wall of the blood-corpuscles, large crystals are formed. Blood obtained, for example, by opening an artery, crystallises in the mass, when defibrinated, evaporated to the consistence of a thick syrup, and rendered venous by having a stream of carbonic acid gas directed on it for a day. This mass has the peculiarity of becoming fluid at the temperature of the hand; a fact which reminds one of the yearly exhibition of the blood of St. Januarius in Naples. The form of the crystals varies from that of needles, to rhombic and rectangular tables and prisms. From further changes in the venous hæmatoglobulin, appear to arise the crystals of hæmatoidin, described by Virchow as existing in all extravasations in the human subject. After four months' careful experiments, Dr. Meckel was unable to find the hæmatoidin crystals of Virchow.

As a direct product from hæmatoglobulin, or indirectly from hæmatoidin, black pigment (hæmatomelanin) is formed in such situations as the lungs and bronchial glands.

Iron and carbon appear to play an important part in these colouring matters; and Melsens asserts that melanin consists of pure carbon, which is most improbable.

The discrepant evidence brought before us by these different observers admits of reconciliation; for it is but rational to suppose that, if the contents of the blood-corpuscles obtained from any organ are susceptible of crystallization, the contents of the corpuscles of the whole of the blood of that animal will yield crystals under proper treatment; so that Lehmann and his fellow-labourers have probably assumed too much in denying the power of crystallization to the blood of many vertebrate animals; whilst the inability of Meckel to obtain the hæmatoidin of Virchow, which has been so minutely described, is no proof whatever of its non-existence. These very discrepancies are evidence of the careful observation and good faith of these investigators; and a comparison of the results arrived at by each shows us on what we may rely as proved by their concurrent testimony, and what we must but provisionally accept until established or disproved hereafter.

Before quitting this subject, we may mention that Dr. FUNKE has succeeded in obtaining crystals from the blood of kittens and swine; that Dr. Parkes has described (*Medical Times and Gazette*, July 31, 1852) some acicular crystals observed by him in some putrefying human blood, which seem identical with the blood-crystals of Reichert, Lehmann, and others, although the details given are insufficient to decide the question of identity. This remark is also applicable to a notice in the *London Journal of Medicine* for Oct. 1852, by Dr. Handfield Jones, on

this subject, where some octohedral crystals, a form very similar on the facets to the tetrahedron, were obtained from hæmiplegic blood. The observer, so far as we can judge, regards them as oxalate of lime; but they were far more probably tetrahedral blood-crystals, soluble, like some protein compounds under given circumstances, in hydrochloric acid.

URINE.

In the *Archiv. der Pharm.*, lix, p. 298, M. NEUBAUER has detailed the results of an analysis of the urine of a dropsical and scrofulous man, aged 20, labouring under tubercles in the lungs and intestines. The urine was brown, of sp. gr. 1.011, and contained

Water	973.50
Earthy Phosphates75
Sulphates	
Albumen	7.50
Uric Acid and Urea (traces)	
Mucus, Salts of Ammonia, etc.	18.25

1000.

According to Berzelius's analysis, healthy urine contains 67 parts of solid matter in 1000, of which about 90 parts are urea, albumen not being noticed as a constituent. The Swedish chemist also has observed that, at the commencement of anasarca, the albumen occurs in such small quantity, that it can only then be recognised by corrosive sublimate. During the progress of the disease, the serous fluids are poured through the urinary passages, and the kidneys also secrete an albuminous liquid, when the albumen may be detected by less delicate tests, such as nitric acid, alum, etc.; and at length it occurs in such quantity as to coagulate by heat. As the amount of albumen increases, that of the urea and uric acid diminishes, until at length they wholly disappear. In the present instance, the albumen readily coagulated on boiling, whilst mere traces of urea and uric acid could be detected; so that the nitrogen thrown off by the body was eliminated by the kidneys as albumen, instead of, as in health, being excreted in the forms of urea and uric acid.

Dr. W. MARCET has investigated the composition of healthy urine, with the object of determining the precise form and state of combination of the proximate organic constituents, as they exist in this secretion; he employs only alcohol and ether as reagents instead of the strong acids and chemicals, which might possibly either decompose these combinations, or effect the transformation of the constituents. The result of these researches clearly establishes the existence of urea in a free and uncombined state; and shows the presence of an acid crystallising in oblique rhombohedra, soluble in boiling water, alcohol, and ether; and which, although resembling hippuric acid in these qualities, differs from it in others, pointing to either a modification of this acid, or it may be a new constituent, hitherto unrecognised, of the urine. A rose-coloured, resinous-like substance was also obtained, which appears to be present in an uncombined state, and susceptible of crystallisation. Further details on these substances are promised.

The colouring matter of urine, which imparts to this liquid its yellow and reddish tint, has occupied the attention of Dr. G. HARLEY, who regards it as a modification of hæmatin, and, like it, in every case containing iron, be its source man or the lower animals. He believes the substance which he has isolated, to be the urine-pigment in a pure state—a conclusion which must be demurred to when the process is considered: but it must be admitted that the substance procured is, at any rate, derived from this colouring matter. As described, it possesses no very specially marked properties; its most conspicuous being solubility in alcohol and ether, and insolubility in water and the strong acids. Dr. Harley observes, that biliary colouring matter, melanin, hæmatin, and this urine-pigment, are closely allied. Whether the first and the last are modifications of hæmatin, is a question worth determining, especially as many circumstances point to this conclusion. We may properly here return to Virchow's researches on a crystalline substance met with in the bile, the *bilifulvin* of Berzelius, which Virchow believes to be a modification of hæmatin. This substance, occurring as reddish-yellow crystals, this observer has met with frequently in the liver and bile of cases involving retention of the bile and chronic catarrh of the gall-bladder, when the bile sometimes appears as a somewhat pasty, clotty mass, of a dark brown colour, and in which some small dark points may be remarked. At these points, under the microscope, acicular yellowish-red crystals of bilifulvin are frequently to be noticed. Virchow finds that this substance possesses characters distinct from those belonging to

hæmatoidin: the feeble action of the strong acids on it is a property common to it and the dark urine-pigment of Dr. Harley. From the action of bilifulvin with various reagents, it seems to occupy a place intermediate to hæmatoidin and melanin in this interesting group of the hæmatin derivatives.

The ground broken in this direction plainly points to the derivation of all these bodies from the blood-pigment or hæmatin, which, after undergoing various changes in the animal economy, is either excreted in a modified state, or is met with in some organ or secretion, giving rise to, or, at any rate, accompanying disease. To trace out these changes, and to explain the alterations which the blood-pigment undergoes in these important transformations, is an achievement which would shed fresh lustre on even the highest scientific reputation.

Liebig's test for urea deserves notice here, even at the risk of its being already known to some of the readers of this Journal; since it is one specially devised by that chemist for the use of the medical man, as being a simple and ready test for the presence of this substance in a liquid, and even as likely to afford an easy means of estimating its quantity. Dr. Hofmann recommends the following modification of Liebig's process:—To add to the urine or liquid under examination, a little solution of red oxide of mercury in nitric acid, and the addition of barytes-water, to neutralise the excess of acid and that liberated by the combination of the urea with the oxide of mercury after each addition of the nitrate of mercury, until the whole of the urea is precipitated. This precipitate is a snow-white and almost insoluble compound, one-five-hundredth of urea being detected by it with certainty. It consists of one equivalent of urea, combined with four equivalents of red oxide of mercury, and one equivalent of nitric acid. The presence of common salt somewhat interferes with the employment of this test in estimating the quantity of urea contained in a liquid.

MM. MICHA and ALVARO REYNOSO, noticing the recognised fact of the existence of sugar in the urine of epileptic patients, remark, that the usual tests will not detect its presence in these cases: thus, neither potash nor the saccharometer are of avail in testing epileptic urine. They are adverse to the employment of Barreswill's liquid, and rightly regard fermentation in the light of the most decisive test with which we are acquainted. It is much to be desired that the assertion of Bernard, that, after wounding a certain portion of the fourth ventricle of a rabbit (somewhat above the origin of the eighth pair of nerves), the urine becomes, after an hour or two, clear and saccharine, and that sugar may be detected in the blood, should be either refuted or confirmed.

M. SOCOLOFF states that he has obtained kreatinin from the urine of the horse, having previously separated the hippuric acid in the usual manner.

URINARY CALCULI.

There are two forms of the triple or ammonio-phosphate of magnesia found in the animal economy, viz., stellated crystals, which may be artificially obtained by adding excess of ammonia to healthy urine, which kind is usually termed the *basic phosphate*; and prismatic crystals, generally trilateral, almost always to be found in putrid urine, and in somewhat modified crystals, at times, even in acid urine. These two forms of this salt have been submitted to analysis by Dr. GRIFFITH, who found that their composition was identical, consisting of 1 equiv. of ammonia, 2 eqs. magnesia, 1 eq. phosphoric acid, and 13 eqs. water, or NH_3 , 2 MgO , PO_5 , 13 HO . The difference of crystalline figure is to be attributed to the different condition under which they are formed; for, as the triple phosphate is less soluble in an ammoniacal solution than in water or urine, when ammonia is added to a solution containing phosphate of magnesia the formation of the crystals is hurried, and the stellate, feathery crystals result; but when only just enough ammonia is present to form the salt, as during the putrefaction of urine where ammonia is gradually evolved, the deposition of the crystals is slow and regular, forming the more perfect prismatic crystals. That this obvious explanation is the true one, is borne out by the occurrence, in some descriptions of guano, of crystals of ammonio-phosphate of magnesia, frequently of nearly an inch in length, the primary form of which is a right rhombic prism. These crystals, described and analysed by Teschemacher, and named by him *guanite*, contain far more ammonia than Dr. Griffith's phosphate; their constitution, according to the discoverer, being represented by the formula PO_5 , 2 NH_3 , 2 MgO , 10 HO .

Similar crystals have since been found in a church-yard in Hamburgh, below a dung-pit which had existed in that spot for centuries. These crystals M. ULEX regards as precisely similar

in composition to the triple phosphate described by Dr. Griffith. The difference of composition assigned to this salt by these chemists is far from satisfactory. The identity of the Hamburgh phosphate with guanite seems to us certain; whilst it is highly probable that the urine phosphate possesses precisely the same composition.

I. MÜLLER describes two cystic oxide calculi, one from the bladder of a man 73 years old, the other from a boy 6½ years of age. The former was about the size of a green walnut, hollow within, but containing in the hollow space a loose nucleus of pure cystin, as large as a broad bean. The shell was of unequal thickness, and exhibited four distinct deposits, one of which was crystallized cystin. The stone taken from the boy was oval in shape, and weighed about 270 grs. It exhibited a confused crystalline structure, enclosed in a thin white shell. The inner portion yielded 55½ per cent. of cystin, the residue being chiefly urate of ammonia, with a little free uric acid, some earthy phosphates and water. Cystin continued to be formed in the urine of this child for eight weeks after the operation.

Dr. BENCE JONES has communicated to the Royal Society some interesting experiments which he instituted upon the solubility of urinary calculi in saline solutions at the temperature of the body in conjunction with electricity. He states that his first essay to produce this result was made in 1848, when he placed uric acid calculi between the electrodes, or poles, of a galvanic battery in a dilute solution of nitre without any very marked result, although some action took place at the negative pole. During the past year these experiments were resumed, and the results with uric acid calculi may be tabulated as follows; the most marked action taking place at the *negative electrode*. Column A represents the number of the experiment; B, its duration; C, the temperature of the solution of nitrate of potash, consisting in every instance of one part of nitre to three of water; D, the power of the galvanic battery; E, the result in grains of uric acid dissolved.

A.	B. Hrs. Min.	C.	D.	E.
1	4 0	212°	10 pairs.	8½ gra.
2	6 5	109	10 "	11 "

9	2 50	Quarter nitre	92	20 .. 2½
10	8 0	Ditto	100	40 .. 5

These experiments prove that a solution of nitrate of potash, in conjunction with the galvanic current, acts energetically on uric acid calculi, at the temperature of the body; but that their mutual action on oxalate of lime calculi is very slow and comparatively insignificant. Dr. Bence Jones states that composite calculi, as mixed urates and oxalates, or oxalates and phosphates, are far more rapidly acted on than oxalate of lime alone.

Some experiments were also made with phosphatic calculi, and solution of one nitre and three water.

A.	B. Hrs. Min.	C.	D.	E.
1	Hard phosphate of lime	7 15	102°	10 pairs. 18 gra.
2	Fusible calculus	1 13	96	20 " 31 gra.

In these instances the chief action was at the *positive electrode*. The author of the memoir concludes from these experiments, that, from two to nine grains of an uric acid calculus can be dissolved in an hour in a solution of nitre at the temperature of the body.

and that from two to twenty-five grains of phosphatic calculus can be dissolved in the same period of time; whilst the mulberry calculus from half a grain to two grains only can be taken up under the same circumstances. If the stone be composed of a mixture of urate and oxalate, from one to two grains may be dissolved in an hour, whilst four and a half to five and a half grains are lost in the same time from a mixed oxalate and phosphatic calculus. These experiments were made with calculi which had long been removed, and which had been dried at 212°. Dr. Bence Jones closes this interesting account by noticing the labours of Prevost and Dumas in this department.

We should rejoice to see the results of some further experiments on this most important subject. This physician has established the fact that some strong saline solutions, in conjunction with the galvanic battery, at the temperature of the body, exert a marked, almost, we may say, an energetic action on the more usual kinds of calculi: but as a means of dissolving a calculus *in situ*, such solutions would be useless, as they would not be borne by the bladder. We trust that these investigations may be pursued, employing *very dilute* saline solutions, such as even an irritable bladder might endure, in conjunction with a constant and gentle current of the solution through the bladder, such as might be kept up by means of a syphon-catheter; and we would venture to suggest that experiments with the organic salts of the alkalis and of ammonia, and the more unstable inorganic salts, might yield results most encouraging to our hopes of the possible adaptation of these means as a perfectly safe and manageable remedial agency in calculous disease.

MIDWIFERY AND DISEASES OF WOMEN.

STOMATITIS MATERNA: ITS SYMPTOMS, ANATOMICAL LESIONS, AND TREATMENT.

INFLAMMATION of the mouth, during the latter stage of pregnancy and lactation, is an affection which is well known in some parts of the United States; and has been made the subject of several essays by our American brethren during the last thirteen years. It is generally described as a disease peculiar to nursing women, which is always troublesome and sometimes fatal. It was first, we believe, described in 1830, by Dr. E. Hale, junr., in a paper published in the *Medical Communications of the Massachusetts Medical Society*, and reprinted in 1842, in the *American Journal of the Medical Sciences*. The disease is more prevalent in some places than in others, as we find Dr. Shanks, of Memphis, Tennessee, stating that "few nursing women of that town escaped it;" whereas Dr. B. W. Taylor, of Monticello, Florida, remarks that "the cases which he has met with in Florida, though perfectly well marked, have been so few and scattered that he thinks it is a comparatively rare disease." Great Britain is by no means exempt from the disease, though we do not remember seeing it noticed by any authors in this country as a recognised complaint. Accidentally, however, some writers have described symptoms which lead us to believe that they had unawares encountered the Stomatitis Materna, or Sore Mouth of Nursing Women, familiar to the profession on the other side of the Atlantic. As we have several times met with profuse salivation, with a clean tongue, and prominent papillæ in nursing women, we are inclined to believe that Members of the Association of larger experience might be able to furnish instructive reminiscences of similar cases, so that their relationship to the American disease may be determined. It is with this view that we now call attention to this subject, which has apparently received very little consideration.

The most circumstantial account of an affection in any way resembling stomatitis materna which we have been able to find in the works of our own countrymen is given by Dr. Blundell, at p. 112, in his account of the diseases of pregnancy, appended to his *Principles and Practice of Obstetric Medicine*, London: 1840. From the tenor of his remarks, and from one case only being referred to, and that being described with some care, we may presume that he considered the affection as one by no means commonly met with. We quote his observations. "Very copious salivation will sometimes occur during gestation, and where the patient has not taken one grain of mercury. I saw a case of this sort, which strongly resembled mercurial ptyalism; but the fœtor was wanting, and the gums were not ulcerated. There was merely the high action of the salivary apparatus. If the quantity of saliva is not very great, the patient may swallow it; and in that manner perhaps she may somewhat moderate the exhaustion which would otherwise occur. My patient, however, secreted the saliva so plentifully,

that when she swallowed it, the stomach was offended, and vomiting ensued. Should the saliva be formed in very large quantities, and should the system suffer considerably in consequence, I should recommend the induction of delivery; which, in all probability, would cure the disease; but where the secretion is smaller, a remedy of this kind would not be justifiable. Meddlesome midwifery is bad. The patient to whom I have just alluded did well without interference."

THE SYMPTOMS of stomatitis materna are thus described by Dr. TAYLOR (*American Jour. of the Med. Sciences*, January 1843):—

"The first symptom is a sensation of soreness and heat of the tongue and lining membrane of the mouth, accompanied by a free discharge of a thin watery fluid, mixed with an increased secretion of saliva, which, in a few days, as the soreness increases, becomes very profuse. The patient compares the pain and heat of the mouth to the sensation produced by scalding. After the disease has progressed for a few days, the lining membrane of the mouth and the tongue exhibits a peculiar red or deep pink colour (as is truly stated by Dr. Barkus), and appears to be much inflamed: the edges and tip of the tongue become slightly ulcerated, being covered with small white pustules closely connected together; and, in some instances, the ulcerations appear upon the lining membrane of the mouth and fauces; and occasionally, if not properly managed, the inflammation and ulceration will extend through the stomach and bowels:—these are the cases which terminate fatally. In the cases I have seen, the ulceration of the edges and tip of the tongue did not exhibit such a tendency to extend deep in the substance of the tongue, as the cases which Dr. E. Hale, junr., describes; but, on the contrary, the ulcers were superficial. The tongue is uniformly free from fur, and singularly clean, having a smooth and polished appearance. This condition of the tongue, its red or deep pink colour, and the thin copious and watery discharge, constitute the chief peculiarities of the disease. The bowels are more or less constive, except in those cases in which the inflammation extends from the mouth and fauces to the bowels, giving rise to diarrhoea. There is usually good appetite; but in consequence of the soreness and pain of the mouth, the patient is obliged to use thin fluid nourishment of the most soothing character, and the blandest mucilaginous drinks; otherwise the pain would be most excruciating. The patient is always clear of fever, but the irritation attendant upon the disease, loss of rest from the pain, and constant drivelling of the saliva, and the inability to take much nourishment in consequence of the soreness of the mouth, all combine in producing great emaciation in many instances. During the whole course of the disease, the secretion of milk is abundant, and the child keeps vigorous and healthy."

ANATOMICAL LESIONS. The following remarks of Dr. J. C. HUBBARD, of Ashtabula, which are of ten years later date than the above account of the symptoms, supply a gap in previous histories of the disease. In the *American Journal of the Med. Sciences*, January 1853, he says:—

"The want of success in the treatment of stomatitis materna results, I conceive, from overlooking certain anatomical lesions which exist in all marked cases. These lesions are ulcerations of the mucous follicles of the intestines. We have seen five ulcers at a *post mortem* examination of a well marked case of the disease, without any other morbid appearances to account for the fatal result. The buccal aphthæ preceded several months the diarrhoea, of which the patient died. The ulcers were circular, about three lines in diameter, indurated and very deep. Three of them were situated in the colon, and two in the ileum. The surrounding surfaces were healthy, or nearly so. A lady, aged 35, had borne three children before coming under my observation, and had severe buccal ulceration during the latter part of each pregnancy, and during lactation; and could get no relief, though she obtained able advice, except by premature weaning, and suffered intolerably with intestinal symptoms, presently to be described. She was first seen by me ten days prior to her fourth lying-in. She had several large aphthæ on the sides of the tongue and cheeks, which were exquisitely painful. She complained of heat in the stomach, and colicky pains. The fecal discharges were solid, but more or less coated by a jelly-like substance, and that often spotted with dots of blood, to use the patient's language. After delivery, she flowed too much. She had irritative fever, darting pain through the colon, and pain, with an urgent sensation of heat, with tenderness about the sigmoid flexure, with fecal discharges, the same as before delivery. The aphthous ulcerations increased in severity and number. She got up slowly; she exchanged her bed for the rocking-chair. An appropriate diet, and the common

medical means, proved of no avail, and the patient anxiously awaited my consent to wean her child. It occurred to me that we should treat her for ulceration of the colon, and it was done."

TREATMENT. Before making any general remarks on this part of the subject, we will continue the quotation from Dr. Hubbard's paper:—

"She was ordered one of the following pills two hours after each regular meal.

"Rx. Sulph. zinci, et
Pulv. ipecac. aa. ʒi.
Resinæ flavæ ʒss.
Pulv. mastich. ʒij.
Tereb. Canad. q. s. F. massa, in pil. lx div.

"To empty the lower intestines just before retiring for the night, with injections of cold water, to be administered slowly, and retained till the water is partially charged with heat.

"At first view, the reader may be tempted to pronounce the recipe a farrago; but when he reflects, that in order to change the character of the unhealthy ulcerations in the colon by medicinal substances, they must be applied directly to the diseased surface, and in sufficient quantities, he will see the propriety of the partially or slowly soluble bases of the pill. The zinc is doubtless the most efficacious drug in the compound; still the ipecacuanha, mastich, and turpentine, are not without value. Three weeks after recourse was had to the above means, the case was decidedly improved, and satisfactory convalescence was soon after established. Six months after, exposure to inclement weather and fatigue brought on a relapse; but a very prompt cure was effected by a resort to the original treatment, and she went through the usual period of lactation without difficulty for the first time.

"I could give an account of seven similar and successive cases, all recovering promptly under like treatment. They all suffered with colicky pains, had mucous discharges, and in several of them a little blood was occasionally present in the stools. Nearly all complained of a sense of heat in the region of the colon.

"I have often noticed that, when the bowels are more painful, and when there is diarrhoea, the ulceration of the mouth is less troublesome, and sometimes suspended for a short time. We would not venture a speculation as to the remote causes of the aphthous diathesis; but the first appreciable warning of its approach is often announced during pregnancy by dyspeptic symptoms, acidity, heat, etc., at first; and finally, colicky pains, and shreddy mucous discharges from the bowels. Irritated by the acrid excretions, I believe that the intestinal follicles first fall into the aphthous condition; and by impairing the digestive function, prolong the period of buccal ulceration, if not directly productive of it. It is needless to add, that many cases will prove fatal under the best directed medication; but when speaking of my own limited experience, I can say that when treatment has been directed to the intestinal lesions, the cures have been surprisingly prompt."

All writers concur in stating that weaning is either sufficient in itself to accomplish a cure, or that it greatly assists in promoting recovery. As weaning has hitherto been considered imperatively necessary in cases of any severity, and as severe cases have often proved fatal, the new principles and plan of treatment promulgated by Dr. Hubbard, if sanctioned by the future experience of himself and others, will entitle him to the thanks of his fellow practitioners.

The treatment recommended in 1843 by Dr. Taylor (from whose paper we have already made an extract), is worthy of attention. It evidently contains some important suggestions, some of which might be combined with the plan of Dr. Hubbard. Dr. Taylor writes as follows:—

"After having tried various tonics, vegetable and mineral, and laxatives, with only partial success, I have found that equal parts of the *flowers of sulphur* and *cream of tartar*, administered in broken doses (two or three times a day), so as to keep the bowels in a soluble state, constitute the best treatment as regards internal remedies. The combination of sulphur and cream of tartar appears to have almost a specific influence over this disease. The best external application, I think, is *borax*, either in the form of solution, sweetened with honey or loaf sugar, or finely pulverized with an equal quantity of loaf sugar, and applied in the same manner as advised by Dr. Dewees in cases of aphthæ in children, only in larger quantity. I have also derived great benefit from a weak solution of nitrate of silver, as a wash. In cases attended with considerable exhaustion of the system, the sulphur and cream of tartar should be only

used to the extent of obviating costiveness, if it exists; and tonics, such as the precipitated carbonate of iron, and the compound tincture or infusion of cinchona, combined with elixir of vitriol, should be given in well regulated doses. Porter is also a good and useful tonic in such cases. Should the case be complicated by diarrhoea, the diet should be bland and farinaceous, as arrow-root, gruel, rice gruel, etc., and the drinks mucilaginous; and an anodyne, as a dose of the solution of the acetate of morphia, or of laudanum, should be given, and repeated *pro re nata*. In refractory cases, it will be necessary to wean the child; and then a speedy cure will be enjoyed."

In the *North-Western Medical and Surgical Journal*, as quoted in the *New York Journ. of Medicine* for November 1851, and *London Journ. of Med.* for March 1852, Professor J. C. EVANS recommends cod-liver oil in this disease. He was led to this by observing its influence in preventing the wasting of the body in phthisis and tabes mesenterica; the diarrhoea and ulceration of the mucous surfaces in stomatitis materna being in many cases similar to those produced by the marasmus in these affections. He has accordingly been in the habit of prescribing it, taken in French brandy or malt liquor, as might be found best suited to the taste or most convenient, and generally with the happiest results. Where the patient would continue its free use, it has proved uniformly beneficial, and in most cases has effected a cure. If this treatment fail to relieve the disease, Dr. Evans observes that weaning should never be deferred until the patient loses her strength, so that she cannot maintain the erect position. Dr. D. L. MCGUIR (in the *Western Medico-Chirurgical Journal*, Oct. 1851) advocates the internal employment of hydriodate of potash, in doses of five grains, three times daily, and a weak solution of the salt as a gargle. A solution of nitrate of silver, in the proportion of five grains to the ounce, applied with a camel's hair pencil to the ulcers, is also, he states, useful. He recommends that, at the same time, tonic medicines and nourishing diet should be given.

CASES OF REAL AND SUPPOSED EXTRA-UTERINE PREGNANCY.

THE following cases have been published during the last and the present year. Their perusal cannot fail to convey important practical lessons.

CASE I. NATURAL DELIVERY IN A CASE IN WHICH THE CESAREAN OPERATION WAS TALKED OF IN CONSEQUENCE OF SUPPOSED EXTRA-UTERINE PREGNANCY. On the 18th of April 1852, a woman, aged 29, was admitted under the care of M. HUGUIER into the Hôpital Beaujon, at Paris, supposed to have hydatid disease of the liver. Being a widow, she at first denied pregnancy, but at last admitted its possibility. The abdominal tumour was situated exactly under the hepatic region, more prominent towards the umbilicus than in the vicinity of the groin, and so high up that the hand, pressing upon the abdomen, easily reached the promontory of the sacrum. The body of the uterus could not be made out by the finger passed into the vagina; but the os tincæ could be felt on the left side far above the pubes. On the right side, and posteriorly to the vagina, an angular body was protruding, which felt like an elbow or a heel, and this was still more palpable through the rectum. The foetus seemed to be lying in the right hypochondrium, where the fetal heart was distinctly heard.

M. Huguier referred the propriety of operative interference to the Surgical Society of Paris, by whom a committee was appointed. The committee were unanimous as to the existence of extra-uterine pregnancy; and agreed that no operation should be attempted till labour had commenced. Subsequently, doubts arose in the mind of M. Danyau, and he again examined the patient with M. Dubois. The latter thought that the pregnancy was not extra-uterine, but that probably the body of the child had lodged in the posterior portion of the uterus, as has been known to happen with the anterior part; so that a limb of the child might be tilted forwards, and there retained in a kind of *cul-de-sac*.

Labour commenced on the 1st of July; and M. Huguier sent for his colleagues M. Roux, and M. Danyau. Preparations were actually made for the operation; when M. Roux made a vaginal examination, and declared that he felt something very like a fetal head. The other surgeons soon ascertained that there was a head presenting; and, after an hour of strong pains, the patient produced a child which lived two hours. On the following day, a vaginal examination was made; but (as before delivery) the body of the uterus could not be felt; and the cervix was found to be as high as it had been on former occasions. From these circumstances, M. Huguier concludes that the uterus of this woman is of a very unusual shape.

The case is chiefly valuable to practitioners, from the caution which it inculcates, in the first place, as to diagnosis in cases of this description; and in the second place, as to the impropriety of resorting to the Cesarean section, so long as there is any doubt of its being possible for the fetus to obtain an exit by the natural passages. This remark is applicable not only to cases of supposed extra-uterine pregnancy, but also to cases of narrow pelvis.

CASE II. EXTRA-UTERINE (PROBABLY OVARIAN) PREGNANCY: DEATH ABOUT THE SIXTH OR SEVENTH WEEK: AUTOPSY. The following is abridged from "Obstetrical Cases", by Dr. J. G. PORTER, of New London, in the *American Journal of the Med. Sciences*, for January 1853.

A married lady, twenty-eight years of age, the mother of three children—the youngest being two years of age—was, on the 15th July 1852, while stooping, suddenly attacked with excruciating pain in the left pelvic region, extending as high as the kidney. Within half-an hour, the pain in a great measure subsided; and under the influence of two grains of opium, entirely ceased. On the following day, tenderness remained where pain had been, but she was able to go about the house. On the 21st she had another attack of pain, which, though similar in character, was more severe. On the 25th, she was similarly attacked for the third time. The pain was excessive; and the prostration was so great, that stimulants in large quantities became necessary to prolong life. There was retention of urine, and (as had been the case for two days previous), a slight sanguineous discharge from the vagina. About twelve hours from the attack a powerful reaction occurred; but afterwards the faintness gradually became more profound, and she died from anæmia, about thirty hours from the commencement of the last attack.

Until three or four weeks before death, the catamenia had been regular, and their cessation at that time was considered to betoken pregnancy. About the time of their non-appearance, being half a mile from home with a child two years old, she was overtaken by a thunder-storm, and ran the whole distance with her child upon her left hip. From this time she never had felt quite well.

Autopsy. The abdomen was prominent and slightly tympanitic. On making the first incision, bloody water gushed out; and on continuing the dissection, the left side of the pelvis was found full of clots and blood, probably in all forty ounces. The left ovary was enlarged to the size of a very small hen's egg, of a dark reddish hue, and adhering to its right side were clots of blood. On removing these and making a slight incision, a small quantity of water escaped, followed by a fetus of perhaps the sixth or seventh week, its size being about that of a honey-bee. The Fallopian tube was found floating freely in the cavity of the abdomen; it was pervious to the probe, and the sanguineous vaginal discharge probably passed through the tube to the uterus.

CASE III. GASTROTOMY IN TUBAL PREGNANCY: RECOVERY. Dr. W. H. BOLING relates, in the *New Orleans Med. and Surg. Journal*, July 1851, a case of extra-uterine pregnancy in a negress, twenty-two years of age, in which gastrotomy was successfully performed by Drs. Bradley and Rogers, of Alabama. The fetus was found in the left Fallopian tube: it was fully formed, about the size of a seventh month child, and would have weighed about five pounds. Four weeks after operation the patient had entirely recovered.

CASE IV. ABDOMINAL PREGNANCY; ACCUMULATION OF FLUID IN ABDOMEN; PARACENTESIS; REACCUMULATION OF FLUID; DEATH. This case is recorded by Dr. F. H. RAMSBOTHAM, in the *Medical Times and Gazette*, for 13th November, 1852.

On February 24th, 1851, Dr. Ramsbotham was called by Mr. Kennedy of Stratford, to see a woman who had borne two or three children, and whose abdomen contained a solid substance of doubtful character. At the end of May, 1850, she had had profuse menorrhagia, which continued till August 4th. Some time before the latter date, she had felt fetal movements, which gradually increased in strength, until, in the beginning of January 1851, she was suddenly seized with spasmodic pains in the abdomen, resembling labour-pains. These lasted about twenty-four hours, and then disappeared; at the same time, the fetal movement ceased. Her general health remained good.

Dr. Ramsbotham found the abdomen as large as that of a woman at the end of pregnancy. It contained a moveable solid body, resembling a doubled fetus; the limbs could be easily traced, floating in a quantity of fluid. The uterus was of natural size, but empty; it was thrown forwards, and the os uteri was canted up behind the pubes by a solid substance be-

tween it and the rectum. He recommended palliative treatment, and that the case should be watched for the present.

She soon began to increase in size, and was again seen by Dr. Ramsbotham on May 24th. A greater accumulation of fluid had taken place. On June 9th, a consultation was held with Mr. Adams, of the London Hospital, who had before seen the patient, and paracentesis was performed; about sixteen ounces of dark matter were evacuated. She was considerably relieved, and continued to perform her domestic duties for above seven months.

In January 1852, her health, which had throughout been good, began to fail. An operation for the removal of the fetus was proposed, but was objected to by herself and her husband. She suddenly got worse, and died on April 24th, worn out with diarrhoea and low fever.

On examination after death, a full-grown well developed fetus, quite putrid, was found lying across the cavity of the abdomen, with the head towards the right side; it was completely shut out from the peritoneum by a cyst of false membrane, which had also become putrid. No placenta could be found, nor any cord, amnion, nor chorion.

CASE V. ABDOMINAL PREGNANCY; PARACENTESIS; EVACUATION OF PORTIONS OF THE FETUS THROUGH THE APERTURE; REMOVAL BY GASTROTOMY; ULCERATED OPENING INTO BOWELS; RECOVERY. This case is related by Dr. RAMSBOTHAM, along with that last quoted.

Mrs. J., aged 28, who had been ten years married, but never pregnant, became so towards the end of July 1834. She evinced all the symptoms of early pregnancy; and at the end of September had considerably increased in size, but observed that she was larger on the left than on the right side. She now became subject to spasmodic pains in the back and epigastrium, so violent as to produce syncope. She felt the child about the end of November, and at the end of April periodical uterine pains came on, with considerable bloody discharge, and evacuation of "stringy matters". These continued, more or less, for nearly a fortnight; they then ceased, and with them the fetal movements, which had become very troublesome. At the end of May, her breasts and limbs had become emaciated: but the abdomen continued getting larger, and the feet swelled.

On July 9th, she was seen by the late Dr. Ramsbotham, sen., and Dr. F. H. Ramsbotham. They "found her greatly emaciated, pulse at 115, tongue furred and dry, respiration laborious, amounting almost to suffocation when she was lying. There was frequent vomiting of white froth, pain in the back, obstinate constipation, constant desire to micturate, while very little urine passed, and with no relief. There were incessant forcing, and cramps in the legs; and she got no sleep. In the abdomen, towards the left side, there was a hard mass, moveable from side to side, and a considerable quantity of fluid, by which it seemed to be surrounded. *Per vaginam*, could be felt a solid substance between the vagina and the rectum; and the os uteri was forced upwards and forwards, evidently unimpregnated."

Dr. Ramsbotham regarded the case as one of ovarian enlargement, complicated with ascites. Tapping was accordingly performed on July 15th, and six pints of thick, sizy, chocolate-coloured fluid were removed. A fortnight after, a small lock of fetal hair passed through the puncture; and subsequently more hair, with globules of oil, small pieces of putrid skin, and membranous strings, which were portions of the amnion and chorion. On September 22nd, she was so much worse, that it was determined to remove the child by incision through the abdominal parietes. This was accordingly done by an incision, five inches in length, parallel with the linea alba; and the child was removed. The placenta was removed on the third day. The patient bore the operation well, and improved steadily for ten days. On the sixteenth day, bile was observed to be passing through the wound, and also intestinal gas, and some curdants which she had eaten in a pudding. An opening by ulceration had evidently been made into the small bowels. Nevertheless, the patient improved, and, in thirty-four days, was walking about her room; and in four months she menstruated. She has not since had a child; but was obliged to leave her husband, through ill usage.

CASE VI. EXTRA-UTERINE FETATION IN A HERNIAL SAC; REMOVAL BY OPERATION; RECOVERY. The following case, related by Dr. SKIRVAN, in the *Wiener Zeitschrift*, is repeated in the *Dublin Quarterly Journal of Medical Science* for February 1853. We have not been able to see the original account of this case; but we have reason to suspect that its exact nature has not been appreciated; and the title prefixed to it is not our's but that given in the *Dublin Journal*.

An otherwise healthy woman, aged 38, had, from childhood, an imperfectly developed inguinal hernia on the left side. She had been delivered eight times without the occurrence of anything abnormal, except that she once gave birth to twins. In consequence of her labours being difficult, the hernia had gradually increased until it attained half the size of a child's head. The patient suffered no other inconvenience from it than that occasioned by its bulk. In October 1850, she experienced, while stooping, a sensation as of a round body falling suddenly into the hernial sac. From that time, the tumour increased in size, and became the seat of pains similar to those caused by a burn, which were relieved by cold applications. Two months later, the patient perceived movements in the tumour, and Dr. Skirvan diagnosed extra-uterine pregnancy, but deferred operating. On April 24th, 1851, pains set in, extending from the sacrum to the hernia; and rapidly increased both in frequency and intensity. The patient having been put under the influence of ether, an incision five inches long was made in the fundus of the tumour, which now reached to the knee; the placenta was then observed, covered with a sero-fibrous envelope, three lines in thickness, the structure of which roughly resembled that of the uterus. The child was extracted living, with the membranes, but died an hour after the operation. The wound soon closed, and the patient recovered completely: the hernia, however, continued as large as it had been before its occupation by the fetus.

CASE VII. OVARIO-TUBAL PREGNANCY: DEATH FROM HÆMORRAGE INTO THE ABDOMEN. The following case is related by Dr. W. L. LANGLEY, in the *Medical Times and Gazette* for February 19th. Mrs. Jane Eliza O'Brien, aged 22, married five months, residing in the town of Athlone, was seized with severe pains, similar to labour pains, early on the morning of the 21st Dec., 1852. I was requested to see her at one o'clock p.m. on that day. She lay in a semiflexed position in bed, with her thighs somewhat bent upon the abdomen, and the legs on the thighs. She looked very pale, anxious, and depressed, and at first indisposed to answer my questions. The pulse was tolerably full and firm, about seventy. She stated that she was five months gone with child, and had strained herself on the previous day whilst spreading clothes to dry on a line; that she suffered from most distressing pain in the small of her back, extending to the abdomen and thighs, the pain as referred to the abdomen being especially distressing. No flooding or discharge of any kind was apparent, nor could the os uteri be felt in the least dilated. She was very desponding, and said she was sure she would die. I ordered an anodyne and slightly stimulating draught, which composed her for some hours; she was again seen at nine o'clock, when the same train of symptoms were observed as in the morning, and the same remedies had recourse to. At ten o'clock she got up to take a drink, became suddenly faint, fell back in the bed, and died almost instantaneously.

Sectio Cadaveris, forty-eight hours after death. On laying the abdomen open, an immense quantity of fluid blood was found, filling up the whole of the pelvic and hypogastric regions, and a fetus of about the fifth month was seen floating in the umbilical region through the transparent membranes, which were whole and perfect, but broke as soon as they were taken in the hand. The umbilical cord was traced to a large rent in a hollow membranous sac, in the right ovarian region, somewhat similar in shape to the womb, to the inside of which the placenta was seen to be adherent, but on further examination the unimpregnated womb was also discovered and laid open for the purpose of tracing its connexion with the other body, which had evidently been the resting place of the fetus, and an imperfect deciduous membrane was found lining the inside of the womb, but the Fallopian tube was impervious, and prevented its transmission to its natural abode. The dilated bag of the ovary was connected with the true uterus by means of the right Fallopian tube, the fimbriated extremity of which covered and was adherent to it. This woman had suffered from pain, and a variety of anomalous sensations in the right groin and lower part of abdomen for several months, at least three or four, but would not submit to an examination.

RECENT EPIDEMIC OF PUERPERAL GANGRENOUS VULVITIS.

The following account is derived from a paper by M. CHAVANNE, in the *Gazette Médicale de Paris* for 1852. The epidemic occurred during January 1850, in the Charité of Lyons.

Several of the puerperal women were attacked, three or four days after delivery, with vomiting and diarrhœa, or with febrile paroxysms and abdominal pains, or slight hæmorrhage. These

symptoms were followed, in twenty-six cases, by lassitude or prostration, and lowness of spirits, and by the development of oedematous redness of the vulva. In a few cases, the disease did not extend beyond this stage, active febrile symptoms becoming, however, developed; but in the great majority, pultaceous plates, resembling Delpech's pulpous form of hospital gangrene, formed on the interior of the vulva and vagina, closely adhering to the mucous membrane. Although their extension became limited in a day or two, they were not separated by the inflammatory process until the end of the first week, or during the second; small, superficial, suppurating wounds being left at the points they occupied, which usually soon healed up, though occasionally degenerating, and becoming covered with the same pultaceous mass. In four of the twenty-six cases, the disease extended to the uterus, and the patients died, having presented all the symptoms of intense puerperal fever, the gangrenous condition of the uterus becoming complicated with peritonitis. No cause could be assigned for the development of the epidemic; both the general sanitary conditions of the establishment, and the prior state of health of the patients, having been satisfactory. In twenty of the cases, the labour was natural, the forceps, however, having been applied eight times; and while the affection seized some of the patients who had very easy labours, others of the inmates, whose cases required active interference, entirely escaped. Besides the four cases above-mentioned as having proved fatal, three others of the twenty-six died from metro-peritonitis, without extension of the gangrene. The other nineteen recovered, the gangrene usually soon yielding to tonic regimen, and the local use of the strong muriatic acid. A very similar epidemic was observed at Lyons, in 1815; and another of the same character has been recently witnessed in Paris.

DISEASES OF CHILDREN.

DR. C. FLEMING ON IRRITABLE BLADDER IN CHILDREN.

In the *Dublin Quarterly Journal of Medical Science* for February, 1853, Dr. CHRISTOPHER FLEMING has commenced what promises to be a highly valuable essay on the Urinary Diseases and Morbid Conditions of the Urine in Children: viz., irritable bladder, incontinence of urine, and retention of urine, together with those morbid derangements in this secretion, attention to which is often important in practice. On the present occasion, he brings under notice the subject of irritability of the bladder.

CRYSTALLINE DEPOSITS. Irritable bladder, Dr. Fleming writes, occurs much more frequently in children than would at first appear, even independently of inflammation or organic disease. "The mother or nurse of the child so affected, states that the child is constantly applying the hand to the organs engaged; that it appears to suffer pain during micturition; that the act is frequent; that it is urgent, but when the urine has passed off the child appears relieved; that often, if the urine falls on the floor or clothes, it rapidly becomes muddy and whitish, and it is even stated by some that it is so at the moment of being passed; that when the child sits down for such purpose, it has an inclination to remain longer than is requisite; and, in some cases, that there is a disposition to prolapsus of the rectum from the forcing and straining attendant, and very frequently a discharge of bloody mucus from the rectum takes place; that these symptoms have continued for some time, notwithstanding the exhibition of medicine to regulate the bowels and produce other ordinary effects; that the child is losing strength, and wasting in flesh; that the appetite is most precarious, and that there is a great desire for drink; that the quantity of urine passed is very variable, sometimes deficient; that its quality is equally changeable, at times being pale, at others deep in colour, and again, clear, and often muddy and with copious sediment."

Children thus affected will often be found to be born of gouty or dyspeptic parents, and to have irregular diet and habits of life, besides being, in the humbler classes, ill-clad and cleansed. In the child, as in the adult, we may have the lithic, the oxalic, and the phosphatic diatheses; in fact, with few exceptions, saccharine diabetes being one worthy of note, every derangement of the urine found in the adult has been found by Dr. Fleming in the child, in its most exaggerated forms. The deposits of uric acid, urate of ammonia, and oxalate of lime, are most frequent; and next in frequency, conjointly with or separately from these, occur blood, pus, occasionally mucus, and very frequently vibriones. Prisms of the neutral triple phosphate may be seen with the crystalline deposits, already

mentioned, but it is very rare to meet with them as solitary deposits. It is also extremely rare, unless under most aggravated disease, to find excessive secretion from the mucous membrane of the bladder. In a case of a boy three years old, who was suffering from irritable bladder, and whose urine was loaded with lithates, and contained a tenacious mucous deposit, with blood-discs and crystals of triple phosphate, Dr. Fleming accidentally found that the alkaline mucus, blood, and phosphates escaped from the rectum, while the urine was acid, and contained lithates with oxalate of lime.

The crystalline deposits in children often occur conjointly; especially the oxalate of lime and urate of ammonia. Lithic acid sometimes occurs as "red sand"; but far more frequently in colourless, or nearly colourless crystals, of every variety of size and form, and in the children of the poor as well as of the rich. When deposits of lithic acid, or of oxalate of lime are present, the physical and chemical characters of the urine are often not remarkable. It is often pale; of sp. grav. 1007 to 1010; and the deposit is a mere tomentous semitransparent cloud. The suffering in these cases may be very great; and the clear condition of the urine may divert attention from an examination of its state.

In the treatment of local or general irritation from the crystalline deposits, the usual dietetic and therapeutic means must be employed; and if these fail, a local cause must be sought for in the bladder or other organ implicated. This state of the urine is most likely to lead to the formation of calculus.

ORGANIZED DEPOSITS. Blood may be present in the urine of children, in large quantity, and yet be attended with not much local or general disease; it may, however, be pathognomonic of renal disease, sometimes malignant. Dr. Fleming has seen a case, in which the urine of a child almost constantly contained a large quantity of blood; it died under twelve months old of encephaloid disease of the kidney. Blood *singly* is a rare addition to the urine of children, except from injury, or from the passage of calculus; but it very rarely attends stone in the bladder in the child.

Pus is much more frequently met with. In girls, when the affection is persistent, local examination must be made, as muco-purulent secretions from the vulva and vagina, often with phosphates, are of frequent occurrence: much urinary irritation may be present. In a case of this kind, Dr. Fleming has found the urine acid, with few pus-globules, but loaded with lithates.

Irritability of the bladder, with pus in the urine, may also occur in girls from an ulcerated fissure of the vagina, analogous to fissure of the rectum in the adult. The principal suffering is referred to the bladder; and the pain before and after micturition is very acute.

Purulent urine, however, Dr. Fleming finds to be more frequent in boys than in girls; and sometimes, like hæmaturia, it is intermittent in its character, and not productive of considerable local or general irritation. The case of a boy aged seven years, admitted under Dr. Fleming's care into the Richmond Hospital, is typical of this form of irritable bladder. Notwithstanding his prolonged sufferings, his bodily health was almost perfect; his symptoms were very severe, and contrasted remarkably with those, comparatively mild, in a boy in an adjoining bed with calculus of the bladder. The irritability of the bladder was almost incessant. The urgency to pass water was great; the agony excruciating towards the end of micturition, and the act only tolerant in the sitting posture. The pain he described as cutting: he referred it to the bladder and the glans penis, and tried to relieve himself by pulling and pinching the prepuce and end of the penis. There was often a sudden interruption to the stream of urine, but by changing his position it recovered itself, and dribbled off. In observing the passing of the urine, its muddiness throughout the whole act of micturition was obvious; the quantity discharged was variable, but always small. There was no incontinence, nor prolapsus. He complained of no pain or tenderness in the lumbar region: but there was—what Dr. Fleming has not unfrequently observed in cases of this kind—great tenderness on pressure and percussion in the supra-pubic region. The disease was of more than twelve months' standing; and was attributed by the boy to having been obliged to keep his bladder painfully distended during school hours. The following was the character of the urine—its usual condition in such cases. "Colour, muddy and whitish; reaction acid; density 1010 to 1012; deposit of rest, an opaque greenish-white stratum, abruptly defined at its upper surface, and about one-fourth of an inch in depth at the bottom of the test-glass. Supernatant fluid almost aqueous, nearly transparent, and, within a limited period, uniformly miscible with deposit. Under the microscope, numerous pus-globules visible. No fibrinous or

tubular casts; no epithelial *débris*; no phosphatic deposit." The bladder was examined for calculus, but none was detected; and Dr. Fleming is certain that where this character exists, calculus will rarely, if ever, be present. In a case, to which he refers, of a child five years of age, there was purulent urine, and an oxalate of lime calculus in the bladder; after death the left ureter was found to have an ulcerated opening near its middle, communicating with an extra-renal tumour, full of fætid and purulent urine.

In ascertaining the source of blood or pus in the urine of children, much must depend on accurate observation of symptoms as they present themselves; and Dr. Fleming finds that *the uniform miscibility of blood or pus with urine, while passing from the urethra, is an invaluable guide in estimating their source.* In nearly all cases of purulent urine in children, the change of the fluid is obvious through the whole act of micturition. In the case above related, he believes that there was renal disease, although there was no lumbar pain or tenderness. In the child, as in the adult, irritable bladder, with purulent urine, has been found connected with disease of the kidneys, the bladder being free from disease. Sometimes this form of disease has its seat in the mucous and sub-mucous membrane of the bladder, and is of strumous origin.

The prognosis is "most unfavourable when the combination of pus, of blood, and of mucus coexists, or even of blood and mucus; and especially if the density of the urine is low, and continues so; if its colour be aqueous; the smell fætid; the reaction alkaline; and the deposit phosphatic: and if the morbid conditions of the urine are attended with lumbar or nephritic pains, and general symptoms of urinary hectic. . . Lumbar symptoms will present themselves in cases of calculus, where the phosphatic diathesis predominates; and hence great caution is required in the diagnosis, lest the operating surgeon should confound them, and materially compromise his character."

Vibrios have been found in the urine, by Dr. Fleming, in many cases of lithic deposits.

Irritable bladder also often attends intestinal worms. In these cases, as well as where vibrios are present, Dr. Fleming finds creasote of great service. He has been in the habit of giving it with benefit in combination with the common aperients of children, and in irritable bladder he constantly orders it, with or without calomel, according to circumstances.

Buchu and uva ursi, with lime or magnesia water, or nitric and hydrochloric acids, are of benefit; and in the chronic cystitis affection, cod-liver oil, alternated with mild preparations of iron, will do much good; and mild counterirritation in the supra-pubic and lumbar regions with tincture of iodine will assist. Sea-air and tepid or cold bathing are valuable in many cases.

It is indispensable to attend to the state of the bladder. In all painful urinary affections, children probably do not entirely empty it; and Dr. Fleming has found in it from four to six ounces of urine, even after great efforts on the part of the child. In such cases, the use of the catheter is necessary. In girls, adhesions of the labia and vagina may induce retention, with most painful symptoms of irritable bladder. Dr. Fleming relates a case in which such symptoms occurred in a child, aged two years, who was recovering from anasarca after scarlatina. He found the labia adherent from before backwards, and a small cribriform veil of mucous membrane covering the orifice of the urethra.* In boys, symptoms resembling those of irritable bladder may (but not necessarily) arise from smallness of the opening in the prepuce, and its great distance from the end of the glans. On observing the passage of urine, it will be found that the stream is scattered, and that the prepuce is distended into a pouch. The author prefers mechanical dilatation of the prepuce to its division.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

SATURDAY, MARCH 5TH, 1853.

JOHN BISHOP, Esq., F.R.S., President, in the chair.

ELECTION OF OFFICERS. The balloting commenced at seven o'clock, and terminated at eight.

After the President had declared the ballot closed,

Mr. C. WING said, that he wished to direct attention to the inconvenient manner in which the election of officers is at present conducted. The names of those already in office were

* Dr. Fleming regards this as one of congenital adhesion of the labia. Yet there had never been any difficulty in passing urine before the attack of scarlatina; and hence we are more disposed to regard the morbid adhesions as the result of scarlatinal vaginitis.

sent, with a list of the Fellows of the Society; and it was a troublesome task to choose from these the persons to fill the vacant offices. He suggested that it would be better for the Council to nominate four or five candidates for each office, and furnish them to the Fellows, in order that they might make their selection from them.

Dr. C. J. HARE objected to Mr. Wing's suggestion, that it was introducing the system of "house-lists".

Dr. SISBON would prefer a return to the system of election formerly pursued in the Westminster Medical Society, before its amalgamation with the Medical Society of London. The candidates for the various offices were nominated openly at one meeting of the Society; and the officers were selected from those nominated, by a ballot at the ensuing meeting.

CALOMEL IN ASIATIC CHOLERA. Mr. TAYLOR read a paper on the *modus operandi* of Calomel in Asiatic Cholera. He supposed that, by the use of calomel, a dysenteric state of the intestinal canal was set up, which was antagonistic to the cholera. He stated that he had been led to this conclusion by having observed some cases in which dysentery appeared to have rendered persons insusceptible of the action of the cholera poison.

ANNIVERSARY MEETING, TUESDAY, MARCH 8TH.

JOHN BISHOP, Esq., President, in the chair.

The society assembled at 5 P.M., in the Thatched House Tavern, St. James's Street.

NEW OFFICERS OF THE SOCIETY. The result of the ballot for the election of officers was declared to be as follows:—

PRESIDENT: Forbes Winslow, M.D. **VICE-PRESIDENTS:** E. Canton; S. Stedman; Tyler Smith, M.D.; John Snow, M.D. **TREASURER:** Henry Hancock. **SECRETARIES IN ORDINARY:** C. Cogswell, M.D.; Edward Smith, M.D. **SECRETARY FOR FOREIGN CORRESPONDENCE:** T. Davidson, M.D. **COUNCILLORS:** R. Barnes, M.D.; J. Bishop, F.R.S.; J. Chippendale; W. D. Chowne, M.D.; J. F. Clarke; J. B. Daniell, M.D.; Victor de Méric, M.D.; W. C. Dendy; R. Druitt, M.D.; A. H. Hassall, M.D.; S. W. J. Merriman, M.D.; John Probert; B. W. Richardson; C. H. Rogers Harrison; C. H. F. Routh, M.D.; W. B. Ryan, M.D.; R. H. Semple, M.D.; W. Smiles, M.D.; J. S. Stocker, M.B.; E. J. Tilt, M.D. **ORATOR FOR THE YEAR 1854:** W. F. Barlow.

DR. SNOW'S ORATION. Our space does not enable us to do more than briefly glance at the very able and interesting address delivered by Dr. SNOW, which was listened to throughout with marked attention, and at its conclusion elicited hearty applause.

The subject of the oration was, "Continuous Molecular Changes, more particularly in their Relation to Disease". The speaker expressed the opinion, that the attraction existing at insensible distances, amongst the atoms or molecules of matter, was a constantly acting force, like that of gravitation. He said, that one of the most important properties of many of the actions or changes resulting from this attraction, was, that they were the cause of their own continuance and extension, as they might observe in combustion and the various kinds of putrefaction and fermentation. In the instance of combustion, they possessed an instrument—the thermometer—with which they could measure the force which extended the action to adjoining materials; but, in the other instances, they had no such instrument. It was in living beings that this continuity of change was most striking; for the actions to which these beings owed their development, were never caused by anything except the previous actions which had preceded them in the same species. These changes, it was true, sometimes admitted of being suspended, but, when they re-commenced, it was in the same materials, and exactly at the point at which they ceased; so that the continuity was not broken. The *matrices morbi* of communicable or contagious diseases resembled the species of living beings, inasmuch as it depended on continuous molecular changes. It also resembled them in the property of increasing and multiplying itself. The epidemic character of diseases was entirely due, in his opinion, to their property of being communicated, either directly or indirectly, from one person to another. He considered that far too much influence had been attributed to atmospheric causes, and to what were called noxious effluvia, in the propagation of epidemic diseases. He said, that even the existence of malaria as a cause of ague had not been proved, and quoted some instances in which intermittent fever had been caused by drinking ditch or marsh water. The cause of these fevers, whatever it might be, probably entered the system by the alimentary canal, and not by the lungs; and agues might possibly belong to the class of communicable diseases, although this character had not been discovered by direct ob-

servation. The communication of tape-worm from person to person had never been observed, although, from various circumstances, it was known to be caused by persons unconsciously swallowing the eggs which had been produced in another patient. He recommended the increased investigation of communicable disease; and concluded with an allusion to the discovery of Jenner, who was one of the early members of this Society.

FOTHERGILLIAN MEDAL. The President presented Alfred Poland, Esq., of Guy's Hospital, with this mark of distinction for his essay on "Wounds and Injuries of the Abdomen, and their Treatment".

THE SOCIETY'S SILVER MEDAL was presented by the President to Nathaniel Clifton, Esq., late Hon. Treasurer of the Society, for the zeal and success with which he had managed its financial affairs, and the great interest which he had uniformly taken in the business of the meetings.

THE DINNER.

Upwards of seventy Fellows and guests sat down to dinner, at 7 o'clock. The President (Mr. Bishop) was supported on the right by Dr. Paris, President of the College of Physicians, and on the left by Mr. Caesar Hawkins, President of the College of Surgeons. Many toasts were proposed, and many speeches made, which, though very suitable for the occasion, do not require to be reported at length. Between the speeches, there was some capital glee and song-singing by professional performers; and everything passed off in the most excellent spirit, every one feeling that such meetings are admirably calculated to remove those angular projections and asperities which must sometimes necessarily arise in connexion with the debates of societies, and the vicissitudes of professional intercourse.

The President successively proposed the Queen, Prince Albert and the Royal Family, the Army and Navy, Dr. Paris and the College of Physicians, Mr. Hawkins and the College of Surgeons. The next toast was Mr. Eyles and the Society of Apothecaries, proposed by Dr. Cormack; then followed the President, proposed by Dr. Paris; the Vice-Presidents, proposed by Dr. Daniell, (and responded to, in an eloquent speech, by Dr. Lankester); the President-Elect, proposed by Dr. Theophilus Thompson; the Treasurer, etc. etc.

In proposing the Medical Society of London, the President stated that it was founded in 1773; and that they were therefore celebrating its eightieth anniversary. The idea of founding the Society had undoubtedly originated with Dr. Lettsom, who was enabled to carry out his ideas with the co-operation of twenty-one distinguished practitioners, among whom were Fothergill, Sims, Jenner, Ware, Woodville, and Babington: and the link connecting the present with the past, existed in the revered Father of the Society, Dr. Clutterbuck. Dr. Lettsom gave the Society its freehold premises in Bolt Court, contributed towards the formation of its library, founded the Margate Infirmary, and introduced vaccination into America. He was President of the Society down to the period of his death. He gave the Society £500 for founding the prize of the gold medal; he also gave £500 to the Physical Society of Guy's Hospital, £500 to the Royal Humane Society, and £500 to the Society of Arts. He was the intimate friend of Benjamin Franklin, with whom he consulted on the best means of averting the calamity of the American war. The Society had always counted amongst its Fellows some of the most distinguished practitioners in London. In their obituary, the Society had to deplore the loss of the following Fellows: Mr. Hooper, Dr. Herbert Mayo, Dr. George Gregory, Dr. Manson, Dr. Bowie, and Mr. Samuel McCulloch. In eighty years, the Society had published ten volumes of Transactions, and had contributed a large series of papers to periodicals. The revenue of the Society was quite sufficient to cover its ordinary expenditure, and, from the judicious management of the Treasurer, there was a considerable balance; and the Society contained within itself the elements for prosecuting researches in medicine and surgery, and for advancing these subjects in connexion with the physical sciences with which their pursuits were so intimately associated.

Dr. PARIS, in returning thanks for his health, (which had been proposed in connection with the College of Physicians,) mentioned that he had a vivid recollection of having been present forty-two years ago, when a student, at some of the meetings of the Medical Society, in Bolt Court. The scene was still vividly impressed on his memory; and he could see at the moment, portrayed before him, the faces and attitudes of the different physicians and surgeons who were there assembled. The general effect was very different from that of a similar meeting of professional men in the present day; for, at that period, all professional men wore wigs and pigtails.

ASSOCIATION INTELLIGENCE.

MEETING AT WORCESTER, TO PETITION AGAINST THE INCOME-TAX IN ITS PRESENT FORM.

A meeting of the members of the medical profession resident in the city and county of Worcester, was held on Thursday, the 3rd instant, in the Board Room of the Worcester Infirmary. It was convened by the Council of the Provincial Medical and Surgical Association, for the purpose of considering the propriety of petitioning Parliament against the income-tax in its present form.

Sir CHARLES HASTINGS, M.D., having been called to the chair, said, that the meeting had been called in consequence of the general feeling that the income-tax pressed upon the medical profession with peculiar hardship. Medical men by no means sought to be relieved from taxes at the expense of any other parts of the community; they only shared in the very general opinion that the income-tax, as a tax on labour, was unjust; that it was unjust to tax the profits of labour in the same proportion as property which had been capitalised. Scientific men, who had given their attention to statistical finance, were of opinion that there was no difficulty in more equitably adjusting the tax; and the medical profession, in common with all others whose livelihood depended on the exertions of their brains or their hands, required, therefore, that its burden should be more fairly distributed. He would now call upon Dr. Malden to lay before the meeting a petition which had been drawn up by the Committee of the Provincial Medical and Surgical Association, and which had also been approved by several other members of the profession in the locality.

Dr. MALDEN (Worcester) said that, as Chairman of the Income-Tax Committee of the Association, it became his duty to read, and propose for the adoption of the meeting, the petition referred to by Sir Charles Hastings; and, in doing so, he must say that that committee was greatly indebted to its admirable secretary, Dr. Thomas Smith, (who had, at much inconvenience, come to attend the meeting that day,) for the manner in which he had made himself acquainted with all the details and bearings of the question. This petition, of course, came before the meeting for adoption, rejection, or amendment. In the petition, allusion was made to all persons dependent on temporary or life incomes; which he was glad, because it had been a question whether the members of the faculty should take this matter up separately, or call a general meeting of the various professions who felt themselves aggrieved by the income-tax. If they had done so, they would no doubt have had a multitudinous assembly; but it was thought that this tax pressed more hardly upon the medical profession than on any other, and that therefore they should address Parliament on the merits of their own case, leaving other professions to follow their example. There was no question that the tax did press with peculiar hardship upon the medical profession; for, while a vast majority of medical practitioners worked harder than any post-boys, and were worse paid, statistics established that their lives, on an average, were much shorter than those of other professional men. Their rest was continually broken, than which nothing tended more to the shortening of life; and they were peculiarly liable to disease and accident. On all these accounts, it had seemed better to the Council of the Provincial Medical and Surgical Association, that the present meeting should be confined to the medical profession. Further details he would leave for Dr. Smith to lay before them.

Dr. Malden then moved the following resolution:—

"That it is the opinion of this meeting, that the income-tax, as now levied, bears unjustly and severely upon the members of the medical profession; and, therefore, that the following petition be agreed to, and afterwards signed by the chairman on behalf of the meeting, and presented to the House of Commons:—

"The Humble Petition of the undersigned Members of the Medical Profession practising in the City and County of Worcester.

"This petition sheweth, That your petitioners only derive from their professional exertions most uncertain and precarious incomes, and which of necessity cease under impaired health, in advanced life, and at death.

"That your petitioners are, for the most part, married men, with families, for whose education and present and future support, under the contingencies of illness, advanced age, and death, they have to provide by these uncertain and precarious incomes.

"That your petitioners feel it a great grievance, and cannot but consider it most unjust, that their professional incomes, thus precarious, should be taxed at the same rate as incomes derived from realised property, which are not affected by the health or age of the possessors, and which descend to their families after their death.

"That your petitioners respectfully submit, that the unequal pressure of the assessed taxes, the higher rate of house-duty, the inquisitorial nature of the income-tax, and its assessment on the maximum amount of the last year's receipts, are felt to be extremely oppressive and unfair towards them, and severely prejudicial to their interests.

"That your petitioners, therefore, humbly pray that, in considering the subject of general taxation, your honourable House will so deal with this impost, if it be indispensable to retain it, as to make it press less grievously upon them, in common with all others depending upon temporary and life incomes."

Dr. THOMAS SMITH (Cheltenham) said that, not being a resident in the county, he could have wished the matter to have been discussed by others who would have come more strictly within the requirements of the advertisement convening the meeting; but, having taken much general interest in the subject of the income-tax, he could not urge any cogent reason why he should not comply with the request of the chairman to take a part in the proceedings. He was convinced that the ill will, engendered by a continuance of the income-tax, would be so great as to compel any minister who might be in office to grapple with it in a manner much more effectual than any that had been at present contemplated. (Hear, hear.) At present, he knew many medical practitioners struggling with difficulties, who felt themselves compelled to make returns which their duty to their families did not warrant, but for which they hoped future success in life would atone. That the returns made to the income-tax commissioners were kept secret, was an absurdity and a farce. He himself last year was obliged to pay his income-tax in the presence of twenty people, every one of whom knew the exact number of pounds he had to put down. Last year, at Cheltenham, one of the income-tax collectors became a defaulter, in consequence of which the board in London made an arbitrary order, against which there was no appeal, that the town should pay a certain part of its income-tax over again; and the assessment papers were left openly at each man's door. He held in his hand now one of these papers, which had been left upon a tradesman's counter, so that all his customers could see how small an amount he paid. Those who did not at once make their returns to the board in London, but placed themselves in the hands of the local boards of commissioners, found themselves in a truly pitiable condition. The supervisor of the district, being paid a per centage on all he got, thought everybody was trying to make his income appear as little as possible, and took a very different estimate of a man's gains to that which he did himself, and generally surcharged him. If he did not appeal, he was set down as a person who had been dishonest: if he did appeal, after being kept waiting for some hours, he was subjected to a vexatious cross-examination, in which he perhaps lost his temper, and so the surcharge was confirmed. He went away like a man who felt himself convicted of a fraud, though he probably knew it was most unjust that he should be required to pay. The person who committed an overt act of smuggling, or adulterated the articles which he sold, was liable to a penalty: the man who had made an unjust return to the income-tax commissioners, was just as much blameable; but the income-tax did not back its own enactments with penalties, because it was known to be unjust in its requirements. The medical profession felt this tax to be peculiarly severe, because theirs was not simply a mere life income; it was only a health income. They moreover were required to pay in much larger proportion than the man in trade; for, while the tradesman's mill, warehouse, cart to carry out his goods, and man to attend to his horse, were all exempt from tax, because these were held to be necessities for his business, the medical man had to pay house-tax at a higher rate than his neighbours, and neither his vehicle, his horse, nor his servant, were exempt, however necessary they might be to carrying on his business. Dr. Smith enlarged upon the difficulties with which many of the medical practitioners had to contend, and the hardship which the tax was to them, especially in its present mode of collection; and he hinted that one reason why they had not more attendants that day, might perhaps be the fear that the eye of the local collector would be upon them, and that he would visit them the next year with a surcharge. He thought nothing would be done effectually towards improving the tax, till the whole system of local assessment was

abolished, and the matter put into the hands of commissioners in London, chosen from the various professions.

The resolution was carried unanimously.

The petition, it was agreed, should be entrusted to the Rt. Hon. Sir John Pakington, Bart., for presentation; and that the various members for the county, city, and boroughs of the county, should be requested to support its prayer.

On the motion of Dr. MALDEN, seconded by Mr. BUDD (Worcester), the thanks of the meeting were voted to Dr. Smith, for his attending the meeting, and the zeal, talent, and industry, which he had displayed as Honorary Secretary to the Income-Tax Committee of the Association.

Dr. TURLEY (Worcester) moved, and Mr. W. C. WEST (Malvern) seconded, a vote of thanks to Sir Charles Hastings, for taking the chair.

Sir CHARLES HASTINGS, in reply, said that the medical profession seldom mixed itself up with the agitations of the day; but there were occasions when it was a duty to step forward and publicly express their sentiments on matters wherein they were deeply interested. As Englishmen, they were ready to pay, and to pay largely, for the blessings of free institutions; but it was for each class to see that it did not bear an unjust share of the burdens. In seeking to remove such an unjust burden from the shoulders of the medical men, he was not coming within the category of agitators. He was only performing his duty in complying with their call to take the chair, and assist them with the important business of that day.

RULES OF THE METROPOLITAN COUNTIES BRANCH OF THE ASSOCIATION.

1. THAT members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION be admitted as members of the Metropolitan Counties Branch, on signifying to the Secretary of the Branch their desire to have their names enrolled.

2. That the power of legislating for this Branch reside in the whole body of its members, the voice of the majority present being decisive.

3. That its executive government be conducted by a Council, consisting of a President, President-elect, an honorary Secretary, a Treasurer, and fifteen ordinary members.

4. That a General Meeting of the Branch shall be held at least once annually, at such place as the members at a General Meeting shall appoint; and that a General Meeting may at any time be called by the Council, on their own authority, and shall also be called by them on receiving a requisition of any ten members of the Branch, such requisition to be advertised in two numbers of the Journal of the Association, prior to the date of the said meeting.

5. That the President-elect be appointed at each Annual Meeting of the Branch, who shall enter on his office at the Annual Meeting next ensuing.

6. That the Secretary and Treasurer be appointed annually, but that they be eligible for re-election.

7. That the fifteen ordinary members of the Council be likewise elected annually, and that all be eligible for re-election, with the exception of the five who have attended the fewest meetings of the Council, who shall not be eligible for one year.

8. That at each Annual Meeting, the members receive the Council's report, elect officers for the ensuing year, transact necessary business, and discuss such subjects, connected with the interests of the profession, as may be brought before them.

9. That all subjects connected with medical science or the profession, be admissible for discussion.

10. That no alteration be made in the constitution, rules, or regulations, nor any rule enacted or abrogated, except at a General Meeting, nor unless special notice of the proposed alteration, enactment, or abrogation be given, either at a General Meeting of the Branch, or to the District Council, through the Secretary, one month before the meeting at which they are to be considered.

11. That the Annual Meeting be held in summer, and at least one month before the Annual General Meeting of the parent Association.

12. That a dinner be provided on the day of the Annual Meeting.

13. That an annual subscription of two shillings and sixpence (due on the 1st of January) be paid by each member to the Treasurer, for the necessary expenses of this Branch.

JOHN FORBES, M.D., *Chairman*.

T. OGIER WARD, M.D., *Hon. Sec.*

BYE-LAWS OF THE BRANCH. At a meeting of the Council, held on Tuesday, February 8th, 1853, the following bye-laws were adopted:—

1. That the ordinary Meetings of Council be held at 4 P.M., on the first Tuesday of February, April, June, October, and December.

2. That special Council Meetings may be called by the President, or Council, or by a requisition of three Members of Council to the Secretary; the nature of the business to be transacted to be stated in the notices for such meetings.

3. That at every Meeting of Council, five constitute a quorum, provided that three at least be ordinary members.

4. That the President of the Branch be, *ex officio*, Chairman of the Meetings of Council.

5. That at all Meetings of Council, in the absence of the President and President elect, the Chairman be chosen by the majority of the members present.

6. That it be the duty of the Secretary to mention, in the summonses announcing the ordinary Meetings of Council, all notices of motions which have been communicated to him in writing by any Member of Council.

7. That the summonses be issued at least seven clear days before the ordinary Meetings; and two clear days before the special Meetings of Council.

8. That all accounts and charges be laid before the Council at the ordinary Meetings; and that all orders for payments be signed by the Chairman and Secretary.

JOHN FORBES, M.D., *Chairman*.

T. OGIER WARD, M.D., *Hon. Sec.*

MEDICAL BENEVOLENT FUND.

At a meeting of the Committee, held on the 22nd of February, letters of acknowledgment of the receipt of grants having been read, Mr. TOYNBEE reported that the £10 placed in his hand for the benefit of a poor medical man, who, with a wife and four out of five children, were destitute, had been applied by him as follows:—Six shillings and sixpence had been paid for an advertisement, through which a situation had been obtained for the father, capable of supporting all his family; and the remainder of the sum of £10 had been devoted to starting them again in a home. There was a balance still due to the treasurer. The treasurer reported that a draft deed of the gift of the six houses, mentioned at the previous meeting, was in his hands.

The following cases were presented:—

i. The widow of a medical man, who died many years since, and who has educated her two children, the one being a medical student, the other a governess. Her sister, who had assisted her, had lately died. Voted £10.

ii. The widow of a medical man, aged 48, supporting herself and five children, by teaching at a school. Voted £10.

iii. A physician in very distressed circumstances, having been unable to succeed in practice, with a wife and eleven children dependent upon him, is anxious for aid to assist him in emigrating to Australia. Voted £30.

iv. The wife of a medical man, with three sons, whose health had slowly declined for some years, and who had lately become insane. Voted £10.

v. A physician in a country town struggling to establish a practice. Voted £5.

vi. A medical man practising in the country, having five children, and in considerable difficulty. Voted £5.

vii. A medical man, of great literary attainments, who has undergone great trials, and whose health is now very bad. Voted £10.

viii. The widow of a country surgeon, aged 63, is entirely dependent upon her children, who are unable to support her. Voted £10.

ix. The wife of a surgeon, she being partly blind, he being insane, having two children dependent upon her for support. Voted £10.

x. The widow of a medical man, destitute on account of the small sum left her, by her husband being detained in a foreign land. Voted £10.

xi. The widow of a young medical man, having two young children to support. Voted £5.

EDITOR'S LETTER BOX.

THE PRESENT OBJECTIONABLE MODE OF CONDUCTING CORONER'S INQUESTS.

LETTER FROM JONATHAN TOOGOOD, M.D., TO THE EDITOR.

SIR,—A FEW years since, I published a letter in the *Times* on this subject, which attracted a good deal of attention, and was subsequently copied into the medical journals, pointing out the mischief which frequently resulted from the appointment to the responsible office of coroner, of ignorant men totally unfitted for it by education or acquirements, and who often sought it to supply the deficiency of income, occasioned by the failure of their original occupation, from their want of ability or of industry. This naturally excited the wrath of these functionaries generally, who assailed me with coarse invective and abuse, in which they were joined by one or two angry medical practitioners, whose unguarded conduct had laid them open to remark. They all failed, however, in refuting my argument, or impugning the truth of my statements. I was therefore convinced that I had taken a step in the right direction; and experience has confirmed that opinion.

In the arbitrary exercise of their office, coroners frequently refuse an investigation into the cause of death, when absolutely necessary, and record verdicts not only at variance with the evidence, but in direct contradiction to facts, which patient examination would have developed. This belief is gaining ground, and becoming so general, that a leading public journal, not long since, summed up an able article in the following words: "The sooner 'Crownser's Quest Law' engages the attention of the Legislature, the better; and it would not be surprising to see one of these days an Act of Parliament passed: 'Whereas, the office of coroner has, by change of circumstances, become cumbersome, useless, and mischievous to the public, be it therefore enacted, etc.' And when this reforming measure shall have received legislative authority, every one will discover what a set of old Charles the coroners were, how utterly unsuited to the present times, and how worthy of every kind of retrospective fun and ridicule."

The office of coroner is, however, in my opinion, one of vital importance. It concerns the morals, the lives, and the liberties of the community. The law, as it stands at present, is totally unsuited to the times, and must be reformed. Coroners do not appear to be guided by any fixed principle of action: they arbitrarily hold inquests unnecessarily, in cases where death has resulted from accident, in the presence of many witnesses, and without a shadow of suspicion; they neglect it in others under precisely similar circumstances; and yielding to the wishes of friends, or the arguments of their legal adviser, they sometimes omit it, in cases of persons found dead in bed without any assignable cause. Each of such instances has occurred more than once in my own practice.

That inquests held by coroners are often solemn farces and mockeries of justice, is as true as that they are often held unnecessarily, and that they "shield off" by their pretended performances, that duty of searching inquiry which is the public's greatest safeguard; and that investigations are sometimes stifled, cannot be denied. These functionaries are sometimes open to conviction, especially in cases in which a lawyer attends to "watch the proceedings" on the part of the friends of the deceased, and spare the feelings of the survivors—a circumstance always open to remark, and sometimes to suspicion.

I proceed to give some examples in corroboration of my statements.

The housekeeper of a friend of mine, mistaking the door of an ashpit for the larder, fell into it. The accident was seen by the master from his dressing-room, and by some of the servants, and she was quickly rescued. She did not appear to be much hurt; notwithstanding, I was desired to see her, when I found that she had broken two ribs. I visited her twice on the following day, and once on the third, when she expressed herself as feeling so little inconvenience, that I did not think it necessary to see her the next day; but just as a servant entered the room that morning, she suddenly expired. An inquest was held, but no medical evidence was called.

A different course was pursued in the following case. I was called into consultation in the case of a gentleman who had been thrown from his horse, and had suffered a fracture of the base of the skull, with great extravasation of blood, from which he died at the expiration of four days, having, after the first twenty-four hours, recovered his consciousness, and given a

distinct account of the accident. His friends did not think an inquest necessary, and preparations were made for the funeral. But on the morning when it was to have taken place, the clergyman of the parish received a *mandamus* from the coroner of the district, who had been made acquainted with the accident by one of his *employees*, not to bury the body until an inquest had been held, which it would not be convenient for him to hold until the following day. The friends were much annoyed at this proceeding; but seeing there was no remedy, they requested the funeral attendants to reassemble on the following morning. I was desired to be present, and met the legal adviser of the family, who contended that an inquest was unnecessary; and, after a short time, succeeded in convincing the coroner, assuring him at the same time that his fee, together with the customary expenses, would be paid. The conclusion appeared to me a proper one, although it was impossible to approve of the means by which it had been arrived at. I do not remember to have seen any report of an inquest on the late Sir Robert Peel, whose death occurred under somewhat similar circumstances.

I am not certain whether a practice, which prevailed some years since, still exists, of employing some idle individual in a parish to report to the coroner any case in which an inquest may be held, by straining the law. The following is an example. I was called to a child, accidentally burnt in the presence of the father, mother, and their nearest neighbour, and who survived the accident three weeks; when it died, and was buried. Fourteen days afterwards, the body was exhumed by order of the coroner, and a verdict of "accidental death" returned. It turned out that a man of the name of Bawden gave notice to the coroner, and received the usual fee of half a crown. Everybody must condemn such an inquest, as a cruel and unjustifiable mockery.

Although cases might be multiplied to an almost unlimited extent, to prove that these statements are grounded on facts, I shall content myself with adducing one instance which fell under my own observation, showing that inquiry is sometimes withheld where it may be justifiable and proper. A lady who had complained of a common cold for two or three days, retired at her usual hour, and was found dead in her bed when the servant went to her room in the morning. No inquiry was made as to the cause of her unexpected death; and this was by some attributed to the fatal event having occurred in the house of an acute lawyer.

It appears from the annexed and other cases, that coroners are not guided by any fixed principle of action. The following is copied from a provincial paper.—"FATAL ACCIDENT. On Wednesday evening last, a man named Haines was knocked down by a van on the Bath road. He died about ten the same night. No inquest was held on the body. The reason assigned for not doing so is, that the recorder will not allow the expenses of the coroner after any person injured has spoken."

The conduct of coroners to medical men has, on some occasions, been not only rash, but impertinent, and extremely reprehensible. This was strongly exemplified in a case of asphyxia from hanging, to which Dr. Shearman, of Rotherham, was called. Under his judicious treatment, the man recovered for a time, but died afterwards of secondary asphyxia. The learned functionary, too ignorant to comprehend the possibility of such a case, not only peremptorily refused the necessary investigation, but slandered the reputation of a highly respectable and intelligent practitioner. (Vide *Provincial Medical and Surgical Journal*, 1844.) He who sitting as judge was bound to confine himself to the evidence, listened to the gossip of a practitioner, who was not a witness before the court; and upon the authority of that gossip, impugned the practice of the medical witness, thereby giving currency to reports injurious to his reputation.

A still more flagrant breach of decorum occurred at an inquest held at West Anstey, before Mr. Partridge, a coroner for Devon, on the body of Elizabeth Tapp. Mr. Trevor, the surgeon who attended the deceased, and to whom she had made an important communication, offered some suggestions which he considered material; upon which the coroner, in the most peremptory manner, ordered him to be silent, and called for the constable to turn him out of the room, after forbidding him to publish any account of the inquest in the papers, declaring that he would ask the jury nothing, but would conduct the case as he thought proper, and according to the "instructions of the magistrates". And this too he did, contrary to the opinion of some of the jury, who would have probably returned a different verdict from that of *felo de se*. This unusual verdict was returned in the absence of all evidence as to the state of mind of the deceased. Mr. Trevor, in a letter to the editor of

the *Exeter and Plymouth Gazette* (vide *Provincial Medical and Surgical Journal*, July 9th, 1845), says: "that the feelings of bereaved parents have been outraged, and the inhabitants of a quiet secluded village have been shocked, by witnessing the stern administration of a barbarous law"; and adds: "but then the coroner got home in time to a late dinner, and the county of Devon was saved twenty-one shillings"; and that he purposely forbears from making any remarks upon the personal rudeness and vulgarity which the learned "judge" of his own court exhibited towards himself, because such conduct from that individual was more a matter of indifference than surprise.

The necessity of making *post mortem* examinations in all doubtful and suspicious cases, is too obvious to be insisted on. I hold it to be the imperative duty of every coroner to direct such an examination to be instituted, unless there exists sufficient apparent cause of death to satisfy the minds of the jury. Such a course ought to have been observed in the case of Elizabeth Tapp, and, *à fortiori*, in the case of James Dimond, who was poisoned with arsenic, administered by that wholesale murderer Sarah Freeman; for if the surgeon had prudently refused to give any evidence, which every man is justified in withholding (unless there be obvious and apparent cause of death), without being allowed to satisfy himself, the coroner must have directed a *post mortem* examination, when arsenic would have been discovered in the stomach, where it was found on the body being exhumed many months afterwards, and the result would probably have been the prevention of two subsequent murders. The fear, however, of the Court of Quarter Sessions is before the eyes of the coroner; and his bill is too often kept down by the rejection of the most important witness. If the reason assigned be the correct one, "that the magistrates are particular as to the expenses", the purse of the public is treated with more respect than their lives. The matter thus stands between the magistrates and coroners. The public mind ought to be set at rest on this point, and the misconception or misrepresentation removed. I cannot imagine that so respectable a body of men, as the county magistrates, would sanction any course which is calculated to impede the proper administration of the law.

I have been induced to offer these remarks, by reading the report of Mr. Hicks's case in the *ASSOCIATION JOURNAL* of the 4th February. It appears that this gentleman has been committed to prison on the coroner's warrant for manslaughter, on the evidence of two practitioners in his own neighbourhood, after a *post mortem* examination made in his absence, and without his knowledge. This proceeding is monstrous. That a mistake in diagnosis (no neglect having been proved) should be followed by imprisonment, is a thing unheard of in the annals of criminal jurisprudence. If such is to be the practice of coroners' courts, and the fate of men who unfortunately commit errors, verily, our prisons must be enlarged to make room for the whole body of medical practitioners; for I believe there is scarcely a candid medical man who has seen any practice, who will not readily admit that he has sometimes arrived at a wrong conclusion. I confess that I am not one of those fortunate practitioners "who never made a mistake in my life". In the course of a long life, and very extensive practice, I have often seen "effects attributed to wrong causes", and sometimes made mistakes in common with men of the highest attainments, and of acknowledged skill and ability. Nor is this matter of surprise in so difficult a science as medicine.

I will not take upon myself to determine whether a member of the medical or legal profession would be the most fit person to preside over a coroner's court; but certain am I, that had one of the former been the judge in the case of Mr. Hicks, he would have been far more competent to deal with the case, and would have subjected the medical witnesses to such a cross-examination, as would have resulted in a juster verdict.

It is, indeed, high time that the whole body of the profession should be "up and stirring", to amend this antiquated law of coroner, and to protect themselves from incompetent coroners, illiterate juries, and malevolent rivals.

I am, etc.,

JONATHAN TOOGOOD, M.D.

The Crescent, Taunton, February 15th, 1853.

HOMŒOPATHY A REACTION AGAINST OVER-DRUGGING.

SIR,—I fancy all candid medical observers regard homœopathy as the reaction against the over-drugging system, which resulted from the practical English public wishing to pay in proportion

to the quantity of medicine they swallowed, owing to their belief that medicine *cured diseases* instead of chiefly *assisting nature*. "My children," said an acquaintance, who had adopted homœopathy, "have got through the measles very well on homœopathic treatment." "So they would with no medicine at all, but with diet, warmth in bed, and a few external applications. Measles, and such like diseases, run their course, and no medicine cures them." "Medicine does not cure measles and scarlet fever? Then I have been always regularly humbugged." This was a *bona fide* conversation. If the public have been accustomed to believe that draughts every four hours, charged at one and sixpence each, are essential to recovery, then they will believe that infinitesimal globules every four hours, at an infinitesimally smaller price, are also as efficacious. The cure, therefore, for this delusion, founded on such premises, lies with ourselves as a body. But again, if legitimate practitioners are not rational ones, they tend to support homœopathy more than all the advertisements, manuals, and fools. To give a case. A young lady comes into the country, out of health. She has a good organization, is essentially a healthy person, but lives on the following *strengthening plan*—rum and milk in bed before breakfast: a glass of wine at eleven: a pint bottle of porter and two glasses of wine at an early dinner at one: a glass of wine at five o'clock, and some again in the evening. She was supplied with saline draughts; with rhubarb draughts; and with chalk mixture if the rhubarb acted too much. Her abdomen was distended. She had constipation alternating with slight diarrhoea, and it turned out that she required castor oil and a simple diet. Now, in such a case, would not a homœopathic doctor have gained credit by merely attending to the diet more reasonably? By advising treatment, so irrational and absurd, members of our own body become the supporters of the silly homœopathic delusion.

I am, etc.,

CARDIUS.

PAYMENT OF MEDICAL REFEREES BY ASSURANCE COMPANIES.

LETTER FROM THE SECRETARIES OF THE MANCHESTER MEDICO-ETHICAL ASSOCIATION, TO THE EDITOR.

SIR,—We are directed by the Committee of the Manchester Medico-Ethical Association, to request the insertion in your columns, for the benefit of the profession at large, of the accompanying "list of Assurance Companies which recognize the principle of remunerating the medical attendants of applicants for insurance, should their professional opinion be sought by the office." We further beg leave to enclose a copy of the report of the proceedings of the Association during the past year, and also a list of practitioners who reside within twenty miles of Manchester, published by the Medico-Ethical Association.

We are, etc.,

JOHN AIKENHEAD,

W. C. WILLIAMSON, } *Hon. Secs.*

Manchester, Feb. 19th, 1853.

List of Life Insurance Companies which recognize the principle of remunerating the medical attendant of an applicant for assurance, should his professional opinion be sought by the office:—

Adamant, Bloomsbury Square, London.
Age, 64, Chancery Lane, London.
Agriculturist, 20, Cockspur Street, Charing Cross, London.
Albert, 11, Waterloo Place, London.
Albion, New Bridge Street, Blackfriars, London.
Athenæum, 30, Sackville Street, Piccadilly, London.
Beacon, 6, Waterloo Place, London.
Britannia, 1, Prince's Street, Bank, London.
British Empire Mutual, 37, New Bridge Street, London.
British Protector, 28, New Bridge Street, London.
British Provident, 4, Chatham Place, Blackfriars, London.
British Mutual, 17, New Bridge Street, Blackfriars, London.
Caledonian, 10, George Street, Edinburgh; and 27, Moorgate Street, London.
Cambrian and Universal, 27, Gresham Street, London.
Catholic, 8, Coventry Street, London.
Church of England, Lothbury, London.
City of Glasgow, 40, St. Vincent Place, Glasgow; and 12, King William Street, London.
City of London, Royal Exchange Buildings, London.
Clerical, Medical, and General, 99, Great Russell Street, Bloomsbury, London.
Commercial and General, 112, Cheapside, London.

County Mutual, Hertford.

Deposit and General, 18, New Bridge St., Blackfriars, London.

East of England, 6, King William Street, London.

Engineers, Masonic, etc., 345, Strand, London.

English and Scottish Law, 12, Waterloo Place, London.

English Widows' Fund, 67, Fleet Street, London.

European, 10, Chatham Place, Blackfriars, London.

General Benefit, 4, Farrington Street, Blackfriars, London.

Great Britain, Waterloo Place, and King William St., London.

Guardian, 11, Lombard Street, London.

Hand-in-Hand, 1, New Bridge Street, Blackfriars, London.

Hope Mutual, 4, Prince's Street, Bank, London.

Imperial, 1, Old Broad Street, and 16, Pall Mall, London.

India and London, King William St., and Waterloo Pl., London.

Indisputable, 72, Lombard Street, London.

Industrial and General, 2, Waterloo Place, London.

Insurance Company of Scotland, 95, George Street, Edinburgh.

Kent, High Street, Maidstone.

Kent Mutual, Old Jewry, London.

Law Property, 30, Essex Street, Strand, London.

Leeds and Yorkshire, Commercial Buildings, Leeds.

Legal and Commercial, 73, Cheapside, London.

Life Association of Scotland, 2, Hanover Street, Edinburgh;

and 20, King William Street, London.

London Assurance Corporation, 7, Royal Exchange, Cornhill,

and 10, Regent Street.

London Mutual, 63, Moorgate Street, London.

London and Provincial, 17, Gracechurch Street, London.

Medical, Invalid, and General, 25, Pall Mall, London.

Medical, Legal, and General, 126, Strand, London.

Mentor, 2, Old Broad Street, London.

Merchant's & Tradesman's, 5, Chatham Pl., Blackfriars, London.

Metropolitan, 3, Prince's Street, Bank, London.

Metropolitan Counties, 27, Regent Street, Waterloo Pl., London.

Mitre, 23, Pall Mall, London.

Mutual, 39, King Street, Cheapside, London.

National Guardian, 19, Moorgate Street, London.

National Loan Fund, 26, Cornhill, London.

National Mercantile, Poultry, London.

National Provincial, 34, Moorgate Street, London.

New Equitable, 449, West Strand, London.

North British, 64, Prince's Street, Edinburgh.

North of England, Old Haymarket, Sheffield; and 11, Cheap-

side, London.

Northern, 3, King Street, Aberdeen; and 1, Moorgate Street,

London.

Phoenix, 1, Leadenhall Street, London.

Prince of Wales, 105, Regent Street, London.

Professional, 76, Cheapside, London.

Protestant, 19, Parliament Street, London.

Provident, 50, Regent Street, London.

Prudential Mutual, 35, Ludgate Hill, London.

Royal, Royal Insurance Buildings, Liverpool; and 29, Lombard

Street, London.

Royal Exchange, Royal Exchange, and 29, Pall Mall, London.

Royal Farmers, 346, Strand, London.

Scottish Equitable, 26, St. Andrew's Square, Edinburgh; and

126, Bishopsgate Street, London.

Scottish Widows, 5, St. Andrew's Square, Edinburgh; and 4,

Royal Exchange Buildings, London.

Solicitors and General, 52, Chancery Lane, London.

Sovereign, 49, St. James's Street, London.

Standard, 3, George Street, Edinburgh; and 82, King William

Street, London.

Star, 48, Moorgate Street, London.

Union, Cornhill, and Baker Street, London.

United Guarantee, 36, Old Jewry, London.

United Kingdom, 8, Waterloo Place, London.

United Kingdom Temperance, 39, Moorgate Street, City,

London.

United Mutual, 54, Charing Cross, London.

United Service and General, 20, Cockspur Street, and Charing

Cross, London.

Universal, 1, King William Street, London.

University, 24, Suffolk Street, Pall Mall, London.

Waterloo, 355, Strand, London.

Wellington Reversionary, 4, Chatham Place, Blackfriars,

London.

Westminster and General, 27, King Street, Covent Garden.

Yorkshire, St. Helen's Square, York; and 12, John Street,

Bedford Row, London.

THE UNIVERSITIES OF LONDON AND EDINBURGH WITH REFERENCE TO PARLIAMENTARY REPRESENTATION.

LETTER FROM DR. SNOW BECK TO THE EDITOR.

SIR,—I feel you will accord me a further space in our Journal, in order to explain some parts of my previous letter.

It is gratifying to know that you consider the claims of the University of London to be elevated to the rank of a Parliamentary constituency, as fully made out. You further say, that even should the University of London succeed in obtaining representatives in Parliament, these members will not represent the medical profession; and "that the great body of the profession in England will not stand quietly by, and see their concerns committed to the keeping of a favoured few." In these sentiments I fully concur. It was never contended that the representation of the London University would represent the great body of the medical profession; nor that this representation should satisfy them; but simply, that through the medical graduates of the University, "medical interests will be more fully attended to in Parliament than they have yet been". It is merely contended that this is a step in the right direction; probably only a first step, and as leading the way for others to follow.

Respecting the value of the degrees of the University of Edinburgh, I am unacquainted with any Act of Parliament, or any Charter, giving to them any power which raises them above "a mere honorary certificate". The degree, so far as I am aware, confers no rights nor authority in the University; the graduates form no part of any corporate body of the University; nor do the degrees give any legal privilege to practise medicine. I have always understood that the degrees of Oxford and of Cambridge alone confer the right to practise medicine in England: the College of Physicians of London, I am aware, has a similar power. But in stating this, I by no means wished to draw any invidious comparison between the degrees of the University of Edinburgh and those of the University of London; for it is well known that the latter has been from its foundation, and is at the present time, in the same position as the former. The metropolitan degrees, equally with those of Edinburgh, are merely honorary, conferring on the possessor no authority in the University, nor giving any right to practise medicine. It is quite possible that those degrees may "constitute the sole legal qualification of many of our most eminent provincial physicians"; but does this not show that these physicians, eminent though they be, are practising without any legal qualification? So far from wishing to degrade the Edinburgh M.D., I intended to point out this singular anomaly—an anomaly which ought to be removed, and which is capable of removal, through the exertions of the graduates. The graduates of the University of London have been so alive to these facts, that for the last five years they have constantly urged the Senate to remove them, by applying for a new charter, incorporating the graduates into the University, and giving them certain rights and privileges. And now, after five years' agitation, there is every reason to believe that this will be conceded. Why should not the same be done in Edinburgh?

The argument, that representatives in Parliament are not likely to be given to an University which does not admit its graduates as members, and give to them a voice in their affairs, is not an argument of mine, but one emanating from ministerial authority. I mentioned it as a practical objection which had been made to the University of London; and which, probably, would be taken to other universities in a similar position, and seeking a similar advantage. I did so under the impression, that it was always a most difficult thing to have any new principle in the representation affirmed by the legislature. I further wished to point out, that it was better to take the present instalment of Parliamentary representation through the University of London, however inadequate that may be to the just demands of the profession, than to wait for the prospective possibility of obtaining it through the University of Edinburgh. My own feelings are in favour of extending the franchise, not to the University of London alone, but to all universities; and I would gladly aid in this object. In discussing these subjects, however, we must not forget that the experience of some years in the attempted legislation for the medical profession has clearly

* The simple fact is, that the diploma of M.D. from a Scottish University entitles a man to practise medicine in any part of the British empire, where there are no local restrictions enforced giving exclusive right of practice as physicians to others.—EDITOR.

shown, that graduates of universities of either of the sister kingdoms cannot be depended upon to represent either the feelings, or the interests, of the English medical practitioners.

I am, etc., T. SNOW BECK, M.D.

February 1853.

PROVIDENT OR SELF-SUPPORTING DISPENSARIES.

LETTER FROM HENRY LILLEY SMITH, Esq., TO THE EDITOR.

SIR,—I shall be obliged by your inserting the following comparison of provident or self-supporting dispensaries, with the present objectionable system of our medical charities:—

OLD SYSTEM.

1. Medical accounts, however moderate, are, except when sickness is of short duration, much beyond the means of the majority of working men.

2. Medical accounts not paid, or deferred till an unpleasant feeling has been created between patient and doctor, totally opposed to feelings of gratitude on the part of patient, and destructive of mutual confidence, which ought to be cherished between them.

3. Quack's medicines, family physic, amateur male and female doctors, or unlicensed practitioners, are of necessity resorted to by the poor.

4. Improvidence, drunkenness, folly in dress, pauperism, and beggary, are begotten, caressed, and encouraged by mere eleemosynary dispensaries, lying-in hospitals, and all the modes of medical charity, which time-servers uphold by balls, bazaars, and all other contrivances, to gild and blazon forth the pseudo-benevolence of the frivolous and the wealthy.

5. Bottle bill, drug bill, day-book, dispenser's salary, wages to errand-boy.

6. Ingratitude, faithlessness, thanklessness, degradation, idleness, and frequently loss of elective franchise.

7. Medical men are separated by jealousy, suspicion, weakness, and unfair competition; while they are likewise subjected to ceaseless toil in one dirty round of street or country duty.

NEW SYSTEM.

1. Payment of one penny per week for adults, and one half-penny for children, brings the best medical advice within the reach of the poorest working men who have employment.

2. Subscriptions paid in advance; and if paid with forfeits for delay, the collector, and not the doctor, bears the obloquy.

3. The qualified practitioners of the Dispensaries resorted to by the poor. [There is no distinction of London, Dublin, Edinburgh, or Glasgow, licentiates, members, or fellows. The lives of rich and poor are of equal value in the sight of God.]

4. Provident habits, sobriety, dress suited to the station in life, and independence encouraged; and the heavenly lessons practically taught to the poor, that it is equally a duty of all to "bear one another's burdens", and to "provide for his own household".

5. No surgery expenses, no bill writing, no bill delivery, no dunning, no courting.

6. Gratitude, respectability, union and thankfulness, industry, and the probability of acquiring the elective franchise.

7. Medical neighbours are brought together and made friendly, forbearing, and accommodating, by learning that they have a common interest in assisting each other, so that they might escape occasionally from the fatigues of practice, without finding on their return that their interests had been neglected or any advantage taken of them during their absence.

I might add to the above list many other indirect advantages likely to spring from teaching the poor to provide for sickness. One of these I will mention, namely, that provident dispensaries might be made the productive nuclei of provident banks and life assurance societies.

Your inserting these remarks in our ASSOCIATION MEDICAL JOURNAL, and calling attention to them, in connexion with your recent well directed censures upon the monstrous abuses of most of our medical charities, may, I trust, be productive of

some good. It will afford me much pleasure to supply information on the subject of this letter, to any member of the profession who may seek for it.

I am etc.,

HENRY LILLEY SMITH.

Southam, Warwickshire, 1st March 1853.

COMPULSORY VACCINATION.

LETTER FROM GEORGE KING, Esq., TO THE EDITOR.

SIR,—In the *Standard* of this evening (Saturday) it is stated that there is a Bill now in the House of Lords, to render vaccination compulsory. Is it possible that such a measure, so affecting the liberty of her Majesty's liege subjects, and so interesting and important to the medical profession, can be passing into a law without their knowing it, or the medical press having heard of it? I hope you will immediately get a copy of this Bill, and let us know in the next number of the ASSOCIATION JOURNAL what it contains, and if the statement of the *Standard* be true. I suppose this is the act of the Poor Law Commissioners; and if they are to have the management of it, it will be adding another insult to the medical and surgical practitioners in England, Ireland, and Scotland. The placing of the Vaccination Act under the control of the Poor Law Commissioners, and Poor Law Guardians, instead of the medical corporations, or medical men, was most iniquitous and degrading to the profession. People will not bring their children to be vaccinated at the beck of the Poor Law Commissioners; there is something revolting in an Englishman's mind to having his children pauperized. Still, I fear, it will be useless to pass Small-pox prevention Acts unless it is made penal for parents to neglect having their children vaccinated before a certain age, say four months; they would then get it done by their own medical attendant, we should have no two shillings or eighteen penny vaccinations, and we should also get rid of the interference of the Poor Law Commissioners. If you give this a place in the Journal, it may lead others to take up the subject, so as to prevent any more wrong being done us by legislation.

I am, etc.,

GEORGE KING.

Bath, March 5th, 1853.

ECONOMY OF THE ECONOMIC LIFE ASSURANCE SOCIETY.

LETTER FROM THOMAS GODFREY, Esq., TO THE EDITOR.

SIR,—I do not know whether the subjoined letter, which bears its own tale, is worth space in our JOURNAL, as a "caution to medical men".

I am, etc.,

THOMAS GODFREY.

Herne Bay, March 6th, 1853.

6, New Bridge Street, Blackfriars,
28th February, 1853.

SIR,—In reply to your favour of the 26th instant, I beg to inform you that it is not the practice of this office to pay a fee to the medical referee of a party whose life is proposed for assurance; it being required that "the proposer do furnish the directors, at his own expense, with evidence of the life proposed being eligible for assurance".

I am, etc.,

A. MACDONALD, Secretary.

THOMAS GODFREY, Esq.

HOMOEOPATHY IN THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

LETTER FROM A PROVINCIAL PHYSICIAN TO THE EDITOR.

SIR,—The facts revealed in the last number of the ASSOCIATION JOURNAL, relative to the proceedings of the governing body of the Royal Medical and Chirurgical Society, render it unquestionable that external legislation is required.

There is another circumstance alluded to, which excites considerable astonishment, and calls aloud for animadversion and correction. It is the "heavy scandal" that a Society expressly instituted for the improvement of medical science, should, even negatively, countenance a system at variance with all science. It is a disgrace to the Society that it should tacitly consent to serve as an advertising medium for adepts in homeopathy;—adepts is the term which best defines the *Cagliostro* of the age.

Professional men in the provinces have ceased to look to the London Colleges and London Societies, administered as they are, for protection against this most fraudulent and insidious of quackeries; but with the faith of a free-trader in the potency of his league, we rely on our own Association for the suppression

of charlatanism, and for the reformation of abuses; and we trust to our own Journal for denouncing both.

The memorable Meeting at Brighton affords every assurance, in spite of corporate supineness, equivalent to breach of privilege, that our Association will continue to maintain the honour and dignity of the profession. Deeply imbued with this conviction,

I remain yours, etc.,
SOCIUS.

March 7th, 1853.

NEWS AND TOPICS OF THE DAY.

CORONER'S INQUESTS AND POST MORTEM EXAMINATIONS. Mr. CARTER, coroner for Kent, lately held an inquest at the Railway Tavern, Dartford, on Elizabeth Reed. A suspicion of foul play existed, and Dr. Culhane performed a *post mortem* examination, as Mr. King, his assistant, could not arrive at a satisfactory conclusion respecting the cause of death. Dr. Culhane informed the coroner that an analysis of the stomach was indispensable, and that it should be made by a competent chemist. The coroner demurred to the proposition for engaging Professor Taylor, as the analysis would cost £6:0, and he could only give the surgeon who performed the necropsy £2:2. At the adjourned inquest, the coroner informed Dr. Culhane that he could fine him £5 for not complying with his warrant, and therefore he called upon him to give evidence of the result of his analysis of deceased's stomach. Dr. Culhane refused compliance for the following three reasons:—1st, want of ability; 2ndly, want of a proper apparatus and analytical experience; 3rdly, want of remuneration. Dr. Culhane called upon the coroner to read a letter which he had received from Professor Taylor upon the subject. The coroner accordingly read the letter, which stated that the want of a proper apparatus, and the absence of experience, rendered it impossible for a medical man to perform a satisfactory analysis of the stomach: that was the result of twenty-five years' experience. There were not twelve men in London competent to make a full and satisfactory analysis. The coroner observed that Baron Parke and Mr. Justice Coleridge recommended an application to the Home Secretary, who would, he had no doubt, order such expenses to be paid. The coroner asked Mr. Callow, the assistant overseer, to sign an order for the analysis, which Mr. Callow declined doing without the auditor's permission; but Mr. Gurnet, one of the churchwardens, undertook the responsibility, and the order was handed to Dr. Culhane for transmission to Professor Taylor, of Guy's Hospital, where the stomach has been lying nearly three weeks. Does not all this show the urgent necessity for a reformation of coroners' courts?

INSANITY. THE PRIZE of twenty guineas, found by Lord St. Leonard's, when Chancellor of Ireland, has been awarded by the Dublin College of Surgeons to Joseph Williams, Esq., M.D., for his essay on "Hypochondriacal Insanity".

EXTRAORDINARY FECUNDITY. On Sunday morning, February 6th, an in-lamb ewe, belonging to Mr. Whiting, of Northampton, died rather suddenly at his barn. She was of a large size, it was supposed from water; but, on being opened, was found to contain six perfect and remarkably fine lambs.

MEMORIAL FROM MEDICAL PRACTITIONERS IN WAKEFIELD AND ITS VICINITY TO THE ROYAL COLLEGE OF SURGEONS.

[TO THE PRESIDENT AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—We, the undersigned members of the College, have seen with great regret that it is your intention to confer the degree of Licentiate in Midwifery on persons who have not previously taken any degree either in medicine or surgery, not have gone through a course of study equal to that required from candidates for the membership of the College; and we feel it incumbent upon us to protest against a measure which we cannot but regard as both unnecessary and mischievous.

The present members of the College, and the licentiates of the Apothecaries' Hall, are amply sufficient to supply the obstetric knowledge and skill required by those classes of the community, among whom the licentiates in midwifery would probably practise.

By adding a new section to the already too numerous

branches of the profession, the difficulty of future legislation on medical subjects will be greatly increased.

The members of the College will be exposed to the competition of a class of practitioners, who have gone through a course of study inferior to that required from themselves; for it is absurd to suppose that the licentiates in midwifery will confine themselves to the practice of that branch of the profession alone. And this competition will be the more injurious, as it will spring from a class of persons who will have some pretence for holding themselves out to the world as qualified practitioners, and who will be so regarded by large classes of the community who know little and care less about the distinction of fellow, member, or licentiate, but who will be apt to regard all who have passed an examination at one and the same place as being on an equal footing; and it is little likely that those who take the license in midwifery without having obtained the diploma of membership, will be unwilling to encourage the delusion, and to act upon it to our disadvantage.

We also fear that the introduction of an inferior class of practitioners into the College will have a tendency to lower the whole body in public estimation; for if, as is very possible, the tone of professional morality of the proposed licentiates in midwifery should be lower than that of the members of the College, any discredit attaching to that circumstance would, in the eye of the public, be to some extent shared by us.

We therefore most earnestly but respectfully beg that you will again take this subject into consideration.

We have the honour to be, Gentlemen,
Your obedient servants,

BEDFORD LENT ASSIZES.

THESE assizes commenced on Thursday, March 3rd. Sir F. Pollock, the Lord Chief Baron, arrived at six o'clock in the evening by special train from Aylesbury, and was met at the Bedford station by H. Littledale, Esq., the High Sheriff, and the usual staff of javelinmen.

CROWN COURT. After the usual proclamations had been read, the Chief Baron charged the Grand Jury. He said the calendar which would be presented to their notice contained neither a large number of prisoners nor a large amount of serious crime. In one case, however, the depositions had not been furnished to him—the case of a surgeon, at an advanced period of his life, charged with manslaughter. He was told, on inquiring for the depositions, that there was some intention of postponing the trial; that, however, was not a sufficient reason for withholding the depositions from him, because, if the case came before them, it might be necessary that he should make some remarks to them upon the evidence to be brought before them. He would urge them to give their most serious attention to this case. If any medical man was guilty of positive carelessness or negligence which resulted in death, he was guilty of the charge of manslaughter; but if the evidence was not very clear—if it was only a case of suspicion, then he would suggest to them to exercise their constitutional function, and see that the charge was really one which should be brought before a jury. It appeared to him that this was a case worthy of their most serious attention.

THE ALLEGED MANSLAUGHTER AT TODDINGTON. Mr. Burcham, on the part of the prosecution, applied for the postponement of

the trial Ward against Hicks, owing to the absence of a material witness. The mother of the deceased child, the subject of this charge, was near her confinement, and quite unable to attend at this assize.

Mr. Power, who appeared for Mr. Hicks, said he was quite sure if his lordship had read the depositions he would have seen that there was no charge against Mr. Hicks, to warrant the verdict of the Coroner's Jury. And with reference to this application he must be allowed to say, that it was too bad to keep the charge hanging over Mr. Hicks for several months longer, when he was prepared to go into the case and show that there was no ground whatever for the accusation.

The Chief Baron: I have already cautioned the Grand Jury against coming to too precipitate a determination.

Mr. Power said he believed that he could satisfy his lordship and the jury that Mr. Hicks's treatment had been most judicious. He was proceeding to make some remarks about the inquest and coroner.

Mr. Bureham objected to these remarks being made. Mrs. Ward was prepared to give further evidence than appeared on the deposition taken at the inquest.

Soon after the application for postponing the trial, the Grand Jury returned

NO TRUE BILL AGAINST MR. HICKS, FOR MANSLAUGHTER.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

- BARNES, J. W., Esq., elected House-Surgeon to the Kent County Ophthalmic Hospital, at Maidstone.
 CLEATON, J. D., Esq., appointed Medical Superintendent of the Lancashire New County Lunatic Asylum, at Rainhill, near Liverpool.
 MUNK, William, M.D., elected Physician to the Small-Pox Hospital, in the room of the late Dr. George Gregory.
 STEVENS, Henry, Esq., elected Resident Medical Officer to St. Luke's Hospital for Lunatics, in the room of Dr. Arlidge, resigned.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were members of the Association.]

- COWDERY, Jonathan, M.D., at Norfolk, U. S., recently, aged 86. He was the oldest surgeon in the American Navy, having served in it fifty-two years.
 CHARLESWORTH, Edward Parker, M.D., at Lincoln, aged 71, on February 21st.
 GORDON, George James, Esq., formerly of the Bengal Medical Service, at 16, Elizabeth Terrace, Westbourne Park Road, February 20th, aged 66.
 JONES, James Cove, M.D., at Southsea, Hants, aged 64, on February 16th.
 MACKAY, William, M.D., late Surgeon in H.M. navy, at Bredgar, near Sittingbourn, Kent, aged 72, on February 6th.
 MANSON, Fredericke Robert, M.D., Physician-Accoucheur to the Royal Pimlico Dispensary, at 33, Park Street, Grosvenor Square, on March 4th, aged 31, in consequence of a poisoned wound received in the performance of his duties.
 MARWOOD, Richard, Esq., Surgeon, at Mount Pleasant, Liverpool, aged 69, on February 23rd.
 McCULLOCH, Samuel, Esq., at 120, Duke Street, Liverpool, on February 20th. He was late senior surgeon to the Liverpool Dispensary, and Consulting-Surgeon to the Liverpool Fever and Workhouse Hospitals; Corresponding Fellow of the Medical Society of London, and Member of the Royal Physical Society of Edinburgh. In his youth, Mr. McCulloch served in Spain, in the Duke of Wellington's army, as Assistant-staff-surgeon to the Royal Horse Artillery, and afterwards with the army on the Canadian frontier. After the close of the war, he practised as a surgeon at Liverpool. He died, after a few days' illness, of a disease of the lungs, produced by exposure to the weather in the course of his professional duties.
 MITCHELL, Henry, Esq., Surgeon, at St. Andrew's Street, Cambridge, aged 34, on March 1st.
 MONCKTON, Jonathan, Esq., Surgeon, at Brenchley, Kent, aged 56, on February 16th.
 PACK, Richard, Esq., Surgeon, at Kilmoganny, co. Kilkenny, Ireland, on February 21st.
 POCOCK, John Innes, Esq., jun., Surgeon, at Exeter, aged 34.

RAE, George, M.D., Surgeon to H. M. S. *Calypso*, at La Guayra, on December 31st, 1852.

RISK, John Erskine, M.D., Royal Navy, at Plymouth, aged 72, on February 15th.

ROBINSON, Simon Davie, M.D., formerly of Bridport, Dorset, at 10, Oxford Street, Cheltenham, aged 76.

ROBSON, William, M.D., late Physician to the Forces, at Edinburgh, on February 20th. Dr. Robson entered the service in March 1805, and served in the Peninsula from Dec. 1811 to the end of the war in 1814, and received the war medal with one clasp for Badajoz.

*STEED, George, M.D., Senior-Physician to the Royal South Hants Infirmary, at Portland Place, Southampton, lately.

WRIGHT, John, Esq., surgeon, at High Pavement, Nottingham, aged 50, lately.

THE ASSOCIATION MEDICAL JOURNAL is published at its own office every Friday evening.

N.B.—Members of the Association receive the Journal, free by post, as a matter of right. To others, the terms of subscription are—For one year, unstamped, £1:6:0; ditto, stamped, £1:10:4.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XI.

LONDON: FRIDAY EVENING, MARCH 18, 1853.

NEW SERIES.

PAYMENT OF SUBSCRIPTIONS. The Law of the Provincial Medical and Surgical Association is as follows:—

“Each Member of the Association shall pay One Guinea annually: the Subscription to commence from the 1st of January in each year, and to be considered as due, unless notice of its being withdrawn be given to the Secretary or Secretaries antecedently to the year for which it would be payable; for such Subscription each Member shall receive a copy of all publications issued for the general use of the Members of the Association.”

Subscriptions may be paid, direct by Post-Office Order, to the Treasurer, SIR CHARLES HASTINGS, or to the General Secretary, JAMES P. SHEPPARD, Esq., of Worcester; through any of the Secretaries of the Branches; and also through Mr. THOMAS JOHN HONEYMAN, the publisher of the Journal, of 37, Great Queen Street, Lincoln's Inn Fields, London.

PUBLIC ESTIMATE OF MEDICINE, AND OF THE OTHER PRACTICAL SCIENCES.

If the last speech from the Throne is to be accepted by the nation as an indication of its political prospects, we may hope ere long to hear that a measure has been brought into Parliament for the purpose of promoting the advancement of Practical Science.

Why such an important measure has slumbered so long in the minds of observing statesmen, is a question too profound to be answered by the writer of to-day. The disadvantages under which men of science labour—the discouragements and insults to which they are constantly subjected—the advantages they offer to the world in their researches—are facts well known to the scientific circle itself, though “invisible or but dimly seen” by the people at large.

The public, however, seems willing at last to open its eyes to the importance of the advancement of science; and our leading public journal, the *Times*, in a late number, has discussed in such admirable terms the value of scientific knowledge, and the degree of unpopularity by which this knowledge is oppressed, that we make no apology to our readers for transcribing these remarks.

The writer has been pleading the cause of the “fine arts”, and then passing on to the defence of practical science, thus proceeds:—

“But is science, it will be asked by some people, a proper subject for national encouragement? On every ground of national obligation we answer in the affirmative. Men of science are the priests of nature, and their researches are a sort of religion. Even their smaller discoveries and the tenour of their information are of immeasurable importance to the world. But science in this country labours under every possible discouragement from its cradle to its grave. So great is the religious suspicion and secular contempt under which it lies, that in most rising and reading families in this country it is thought a positive misfortune when a child betrays a scientific taste. When a friend or a

phrenologist, or the lad's own schoolmaster, proclaims that he has no aptitude for words, for composition, or for criticism, but a craving for facts, a readiness to receive material impressions, or ideas of form and beauty, the countenance of the parent falls, and it is felt throughout the family circle that the lad is a positive misfortune, and had better never been born. What is to be done with him? What respectable profession can he embrace? What school can he go to? What associates must he mix with? How is he ever to get his living? Nor are these apprehensions ill-founded. The young Newton or Faraday is out of place at home, at school, and at college. To pursue the natural bent of his mind is the worst sin he can be guilty of; and, if his anxious mother hears that he has made a telescope, or produced a tumbler of carbonic acid gas, she thinks his doom all the more sealed. The boy is out of place at school, from which all consideration of the material universe is absolutely excluded; unless the names of cities that no longer exist, and rivers that cannot be identified, be thought material facts. At college, we believe, something like a *habitat* and an occupation is hereafter to be found for the unfortunate youth, but hitherto there has been none. Indeed, at Oxford it is at present much better that the student should not know anything that the world has discovered or learnt since the revival of Greek literature in the fifteenth century. Nor, supposing this long Slough of Despond fairly passed through, is there anything to look forward to in the way of prize, distinction, or even maintenance. It is true, that here and there a scientific youth may become a railway engineer, and even speculate to advantage in that line. He may perhaps discover a good patent, and sell it for a round sum. But, if he confines himself to science, there is nothing for him but to pick up a precarious subsistence by lecturing at institutions, and at the very few schools and colleges where science is allowed. Rank, estimation, he can scarcely hope to attain, unless by the by-path of mercantile speculation, oftener disastrous than not. Now, it cannot be for the advantage of a country, as it certainly is not seemly and really natural, that the knowledge of the material universe should be under such serious discouragement, not to say disparagement. It ought to be a regular profession, with its teaching, its progress, its prizes, its preferments, and some share of those honours and dignities that, enjoyed by few, stimulate the ambition of many and reflect a lustre over all.”

After so truthful a description of the present condition of the sciences, it would be unnecessary for us to enter on the subject in its general sense. We may, however, with considerable advantage, consider the matter in relation to our own science—the science of medicine.

That the profession of medicine, wherever truthfully practised, is, in importance and usefulness, the first of all the practical sciences, few, we presume, are prepared to deny. Its worth is not to be seen only, but to be felt also: seen always in its universality—felt often by every one in its speciality. In civilised communities, there lives scarcely a man who, sometime or other in his life, seeks not the assistance of medical science, reaps not its benefits. In uncivilised communities, it is the civilised blessing first hailed, and is often the only one that remains blessed. For the acquisition of scientific medical knowledge, the most healthy mind is required, the most industrious hand, the most

watchful eye. In the administrator of this knowledge, there must be a resolute determination, a high sense of justice, a gentlemanly demeanour, a kind heart. He, moreover, who would shine as the true scientific physician, must grasp in his educational pursuits a general knowledge of all sciences. These are but a few of the qualifications and labours which bind themselves more or less closely round the conscientious medical practitioner.

And yet, and as if to prove what we believe to be the fact, that in this country the actual worth of a science is in the inverse ratio to its value in the public eye, the profession of medicine is, of all professions, callings, and trades, the one least assisted, the one most grievously contemned. The youth, who with energetic mind, with sufficient resolution to meet ordinary trials, and with a determination to advance his profession, to live *for* it—as well as *by* it; the youth, we repeat, who with these qualifications enters the profession of medicine, hoping that time, sooner or later, will proffer a little of that honey with which the portions of others in life are sweetened, finds, when the grey hair crowns his head, that hyssop is still his portion. What more, indeed, can come to him? Watched by the public as by an omnipresent gendarme, he must at all time be chary not to offend the morality of this most righteous inspector, either in word or in deed. If a general practitioner, he may have to undertake, forsooth, the duties of an union practice, and to find himself placed betwixt Scylla and Charybdis—the board of guardians the Scylla, the unfortunate poor the Charybdis. The man has two masters in such a case, and he cannot, with the slightest chance of happiness, serve both. If, again, the medical man exhibit a devotion to the pursuit of general science and general literature, he becomes distrusted on all sides, is dubbed *theorist*, *sceptic*—anything in fact but a practitioner in whom the public can place confidence. If by an accident he commit a real or supposed error in his practice, an error, which if real, no wisdom, perchance, could have foreseen, and which happening to a man in another occupation would excite pity, he is subjected to the most ignorant and unfeeling criticisms; criticisms which often emanate from the tea-table, and have their roots in minds puerile from senility. Lastly, if the scientific medical man spend his talents in promoting the interests of his own science, he does so under every disparagement. To meet the severe but necessary criticism of his compeers is no trifling matter, but is as nothing to the chilling carelessness with which the world receives his labours. Honours but few, and these rendered almost dishonourable by unworthy distribution, wait for him. Fortune and wealth must not be dreamed of; the grateful love of an obliging people it would be madness to expect. Nothing, in truth, remains for him to hope for, save that in some future day more kindly eyes may peruse his labours, and more thankful lips speak his praise; a last hope, cheerless as the grave in which he will lie before an appreciation of his worth shall be realised.

We might, if space permitted, refer to the slight value which is attached to the gratuitous services of the officers of public charities, and to the manner in which people patronize the veriest impostors in medicine, and even insolently compare the assumed skill of such impostors, with the knowledge of those who practise the healing science faithfully and skilfully. The end, however, which we had in view is attained. We desired to show the usefulness of scientific medical knowledge, and the low estimation in which that knowledge is held by the public. The descriptions which we have given are sufficient to illustrate,

that it is necessary for every man who sincerely loves the profession of medicine, to demand from our legislature, that in any scheme for the advancement of practical science, due attention be paid to the interests of the medical body; that the true medical inquirer be no longer forced to go on in his labours of love, uncared for and unknown; and that quacks of all kinds, in lieu of being shielded by the law, be exposed to its just severities, as enemies of morality, and traitors to the commonweal.

DEATH OF ORFILA.

IN our last number we discharged the pleasing duty of recording the munificence and good judgment with which ORFILA had bestowed a large portion of his ample fortune upon objects connected with the advancement of medical science, and the encouragement of those who labour in that sacred cause. To-day it is our melancholy office to record the death of this truly good man. The kindness of heart and urbanity of manners of Orfila have been felt, we doubt not, by many of our readers; and few will join more sincerely with our colleagues in France, in deploring his loss, and in reverently embalming his memory with the recollection of his scientific achievements and his social virtues, than those Englishmen who have studied medicine in Paris during the last twenty-five years.

Orfila died at Paris, on Saturday last, the 12th, and was buried on Monday the 14th. The brief space allowed to elapse between his death and funeral has justly occasioned surprise and dissatisfaction in the French capital. We understand that the deceased had been suffering from phthisis for some time past; but at last his death was rather sudden. He was able to dine with the Parisian Medical Society on the 26th of February. Since that time, however, we have observed notices of his bad state of health in the French papers, but we have, likewise, repeatedly seen it mentioned in them that his life was not supposed to be in danger. It now appears, however, that his friends and physicians, Chomel, Andral, and Rostan, had despaired of him for some days before his death; and that this was carefully concealed from the newspapers, as the illustrious invalid insisted upon reading what the daily journals contained regarding his health.

The career of Orfila marks a memorable epoch in the progress of medical science, commencing, in 1814, with the publication of the first edition of his *Toxicology*, and closing with the events of yesterday,—his benefactions to science, and his burial in the cemetery of Mont Parnasse, close to the tomb of Baruel, one of his first preceptors. Before the appearance of Orfila's work, *Toxicology* had few cultivators, no teachers in the schools, and little claim to be regarded as a science: now, it is zealously studied in all countries, taught in every school, and so simplified by the labours of many eminent men, as to be practically available, by every educated practitioner, in the detection of crime, and in the preservation of life. It is remarkable that the great champion of French science, whose death we are now lamenting, should, like Napoleon, the great soldier of France, have owed his birth-place and his blood to a foreign soil. Napoleon was born in Corsica, and was the son of a Corsican; and Orfila, though a naturalized Frenchman, and for many years Dean of the Medical Faculty of Paris, was by descent a Spaniard. He was born in Spain, at the frontier town of Mahon, and studied at a Spanish university—~~at~~ Valencia—during the first years of his medical career.

ORIGINAL COMMUNICATIONS.

HISTORY OF A FEW CASES ILLUSTRATIVE OF THE USE OF THE FORCEPS IN DIFFICULT LABOUR.

By EDWARD WILLIAM MURPHY, M.D., Professor of Midwifery in University College, and Obstetric Physician to University College Hospital.

(Read before the Medical Society of London, Feb. 26, 1853.)

QUESTIONS connected with the use of instruments in difficult labour are so embarrassing, and have given rise to such warm controversies, that any light which may be thrown upon them by individual experience is of value. With this object, I have ventured to bring before the Medical Society a few cases of difficult labour, which required instrumental aid; and which, it appears to me, illustrate some important points connected with this subject. One of these questions concerns the comparative merits of the crotchet and the forceps, as a means of delivery when the head is fixed in the brim of the ovate pelvis. Some practitioners do not hesitate to perforate the head in these cases; they consider that the safety of the patient requires it, and object strongly to the forceps as a dangerous instrument under such circumstances. I believe that these objections have no foundation in fact. On the contrary, I am inclined to the opinion, that not only in these cases may the long forceps be safely used, but that even in some of those where the head has not entered the brim of the pelvis in consequence of disproportion, it may be made to do so by this means, or by the operation of turning the child. These observations apply exclusively to the ovate deformity of the pelvis, where the whole difficulty exists in the diminished conjugate measurement of the brim.

Some years ago, I met with a case which enlightened me very much on this question, and made me hesitate greatly as to the propriety of perforating the head of the child when thus situated. A lady had been in labour of her twelfth child, each labour being more and more difficult. The head was above the brim, and so remained the whole night, apparently prevented from entering the pelvic cavity by want of space in the conjugate axis. I attempted to apply the long forceps; but, after several efforts, failed. No alternative seemed left to me but to perforate. I proceeded with great reluctance to the operation, and very fortunately pushed the head with the perforator from the brim towards the iliac fossa. The arm came down, and I immediately proceeded to turn the child, in which I completely succeeded, and delivered it alive. Having this useful lesson strongly impressed upon my mind, I met soon afterwards with the following instance.

CASE I. PELVIS CONTRACTED IN CONJUGATE AXIS TWO INCHES AND THREE QUARTERS: DELIVERY BY TURNING THE CHILD. On February 25th, 1848, I was sent for to see a hospital patient, living in King William Street, Strand. She had applied several months previously at University College Hospital, for aid in her confinement, and had been twenty-hours in labour before I saw her. The os uteri was nearly dilated, the head resting on the brim of the pelvis. She was a pale delicate looking woman, and very intolerant of her pains, which caused her great agony. The pelvis was contracted in the conjugate axis of the brim, as nearly as I could judge, to two inches and three quarters, certainly not quite three inches; the cavity was wide, and also the outlet, only that the coccyx was bent so much forwards as to become an obstruction. I saw no probability that labour, no matter how long continued, should terminate naturally; and there remained only the choice of allowing labour to continue some hours longer, in the hope that the head might enter within the brim, or to deliver at once. I preferred the latter course, because I did not wish to expose the woman to any great protraction of her intense suffering, and I wished to give the child the best chance for its life.

She was placed under the influence of chloroform, sufficiently to blunt the intensity of her pains; and having allowed labour to continue for a little time under its use, I proceeded to apply the long forceps (that which I used was straight). I found it, however, impossible to act with it; because, when the blades were applied to the head, the shaft and handles pressed strongly against the perineum and coccyx, which was bent so much forwards, that no efforts could prevent the handles taking the same direction, and the blades, of course, the opposite one,—that is, off the head. I threw them aside, and determined to make the attempt to turn the child. The perineum and coccyx opposed greatly the passage of the hand and arm, and there was much difficulty in directing it towards the brim of the pelvis (the axis of the brim and that of the outlet were at an angle of nearly 45°). The hand, however, passed through the brim more easily than I expected, and a limb of the child was brought down, but not without some trouble. Want of space in the passages made it equally difficult to reach and bring down the remaining limbs; however, the body was brought through the pelvis safely, but the head still remained. The finger was placed within the mouth, the back of the neck seized, and the hands made to correspond as nearly as possible with the transverse axis of the pelvis; extraction was then made, but, after several efforts, I could not move the head. The funis still pulsated; and having placed it out of reach of pressure, I allowed the patient a little rest. Efforts were again made to extract, which at length succeeded, but the child was still-born, the bones being very strongly overlapped. I think that its death occurred while the head was passing the brim; because pressure on the funis was unavoidable, and this was too long continued, in consequence of the delay in the transit.

So far as the extraction of the child through the pelvis is concerned, this was by far the most difficult operation of turning I ever had to perform,—not so much from contraction in the brim as from want of space in the outlet, in consequence of the abrupt curve of the coccyx. The woman recovered without a single unfavourable symptom.

The result of this case convinced me of the practicability of turning in this degree of disproportion; and the child was so nearly saved, that it seemed to me to afford a powerful evidence in its favour over perforation. The only doubt I had was, whether I might not have succeeded as well, if not better, had I used a curved in place of a straight forceps in the first instance. I thought that the curve of the forceps, corresponding to the curve of the coccyx, might have enabled me to apply the instrument more easily. This doubt was removed in the following year (1849), when the same woman applied for aid under precisely similar circumstances. She was again pregnant; labour took place in March. She was under the care of a very intelligent pupil; and as soon as the os uteri was fully dilated, I determined on delivering her. I brought for the purpose a forceps strongly curved, but found it just as difficult to apply as the straight one that I had tried before. I therefore had recourse again to turning the child, in which I experienced nearly the same difficulty as on the previous occasion; the child, also, was still-born.

Had this patient come for assistance at the seventh month, when she was desired, I have no doubt that the child could have been saved. She recovered from this labour equally well: and the results of the operation in both instances convinced me that perforation was a most unjustifiable operation to adopt, in cases where the disproportion in the conjugate axis of an ovate pelvis exceeded two inches and a half. This view was confirmed by the following case.

In November 1847, I delivered a woman by perforation, in consequence of a contracted pelvis. As it was the first case in which I had the opportunity of using chloroform, and judging of its effects, I reported it in a tract published in 1848, entitled *Chloroform in the Practice of Midwifery*; and from that publication I shall quote as much as is necessary for the subsequent history.

CASE II. CONTRACTED PELVIS, TWO INCHES AND A HALF FROM PUBIS TO SACRUM: DELIVERY BY PERFORATION, AFTER THIRTY-NINE HOURS' LABOUR. E. G., aged 36, living in Grove Street, Camden Town, of moderate height and delicate appearance, was taken in labour with her seventh child, Nov. 24th, 1847. All her previous labours had been protracted, varying from fifty-six to eighty hours, and all her children (males, with one exception) had been still-born. In her last confinement, after being sixty hours in labour, she was delivered by the forceps of a dead child. Her present labour commenced November 24th, at six o'clock, A.M., and the pains continued without interruption the whole of that day and night. She was seen on the following morning about eleven o'clock. The os uteri was nearly dilated, the vagina moist and cool, the head above the brim of the pelvis, and its conjugate measurement contracted to two inches and a half. It was evident that the head could not descend into the pelvic cavity; but labour was suffered to proceed, in order to ascertain whether it might enter the pelvis sufficiently to be extracted by the long forceps. She was seen again in the evening, at half-past eight o'clock, having been left in charge of the gentleman in attendance during the day. She had now been more than thirty-eight hours in labour, during the whole of which time she had very strong and regular pains, but without any alteration in the position of the head; the writer therefore determined on delivery by perforation.* This woman had been placed under the influence of chloroform, delivered, and made so favourable a recovery, that she was walking about Camden Town three weeks afterwards. She had been very strictly charged to apply at the hospital before the seventh month, if she should ever again become pregnant. She did so in 1849. Premature labour was induced; the child presented the breech, and was delivered still-born.

The same charge was again given to her, but she neglected to attend to it. She became pregnant in 1851, and gave us no notice of it until near the full term. I have reason to know that she was quite determined not to have children: the last child was very nearly saved, and she was not solicitous to go through the same ordeal again to save another. I therefore did not see her until she was in labour. I called in the evening, and found the os tincæ nearly dilated, the head above the brim. I might then have delivered her as before; but the same determination which led her in one direction, led me in another and an opposite one. She cared only about saving herself: I was resolved to use every effort to save the child. I therefore allowed labour to go on for twenty-four hours, in charge of the gentleman in attendance; and, although frequently solicited to deliver her, did not see her until the following evening. I delayed, in the hope that the head might possibly be forced within the brim of the pelvis, so that I might apply the long forceps; and was greatly pleased to find my wishes realised. I found the head fixed there. She was again placed under the influence of chloroform; the long straight forceps were applied, and with extreme difficulty the head was brought through the brim into the cavity, from which it was easily extracted. I could not, however, save the child: its death was caused by the extreme pressure of the brim, which was so great as to produce an indentation in the cranium of two or three lines in depth. As on former occasions, so in this, she recovered perfectly, without any drawback.

The case was a very instructive one, because, when I first saw her in 1847, the pelvis had been very accurately measured, and the conjugate axis did not exceed two and a half inches—a space through which it seemed to me impossible for the unreduced head of the child to pass. Let the vault of the cranium be compressed as it may, still the transverse measurement of the base is two and a half inches; and, therefore, the inference must be that it would not pass: but it did so nevertheless; and I can only attribute it to the expansion of the pelvis—the head, like a powerful wedge, stretching the symphysis pubis and sacro-

iliac articulations to their utmost extent. The conclusion, therefore, at which I arrived, was, that whatever doubt might exist as to the propriety of attempting to deliver with the forceps, or by turning, when the conjugate axis was two and a half inches, there was no question about it when the space exceeded that amount; and that a diminution to three inches, or even to two and three-fourth inches, would not be too great to make it possible to avoid perforation.

CASE III. CHILDREN STILL-BORN IN SEVEN SUCCESSIVE LABOURS: CRANIOTOMY SEVERAL TIMES: DELIVERY BY FORCEPS IN EIGHTH LABOUR: CHILD ALIVE. The above view was supported by a case that I was requested by Mr. Collins, of Camden Town, to see, in July 1851. His patient had been in labour of her eighth child, not one of the previous children being born living, and several of them delivered by craniotomy; so much so that, when I was sent for, she expected that, like preceding consulted accoucheurs, I should proceed at once to deliver by perforating the head. I saw her at midnight, and found the os uteri nearly open, the membranes ruptured, and the head above the brim of the pelvis. I could pass the four fingers of my left hand easily within it, and judged that the degree of disproportion in the conjugate axis was about three inches. I might have then turned the child, but I preferred allowing the labour to proceed, in the hope that the head would get within the brim of the pelvis. Having arranged with Mr. Collins to see her sooner, if he thought necessary, we agreed to meet the following day at twelve o'clock, leaving her to nature for twelve hours more. When I arrived, what I hoped for had taken place: the head of the child had entered and remained fixed in the brim of the pelvis. The long forceps was at once applied; and, after several powerful efforts were made, the head at length moved, and I succeeded in bringing it into the cavity, from whence it was easily extracted. The child was born living, greatly to the astonishment of the mother (a woman in humble circumstances) and her nurse; both of whom imagined that, as on former occasions, it must be destroyed. So little did she expect to hear its cry, that she had no baby-clothes prepared for it, which caused some little confusion. This woman recovered without any unfavourable symptoms.

Taking these cases collectively, they seem to me to determine some of those questions that I would submit:—1st, Whether, in the ovate deformity of the pelvis, we are justified in perforating the head and destroying the child, when the head is fixed in the brim of the pelvis? This, I think, will be answered in the negative. 2ndly, When the head has not entered the brim of the pelvis, what amount of space in the conjugate axis will justify the attempt to save the child, either by the long forceps, or by turning? I think we may do so, if it exceed two and a half inches. The probability of saving it may be slight, but still it is by no means impossible; and, as the necessity for destroying it is not proved in such cases, we are not justified in doing so.

When the head of the child has entered the pelvic cavity, and ceases to advance, the arrest may be caused by a slight deformity of the cordiform character; that is, the planes of the ischia may be pressed inwards sufficiently to prevent the rotation of the head. No further progress is made, and the head is said to be impacted; the ear cannot be touched without great difficulty; and it is impossible to pass the finger laterally between the head and the pelvis. The treatment of such cases as these became a question of great interest to me soon after my arrival in London, because the propriety of using the forceps when the head was "impacted", was very warmly disputed by no mean authorities in obstetrics; and my own experience was decidedly opposed to any such attempt, in the kind of cases that came under my observation when a resident physician in the Dublin Lying-in Hospital. The cases of impaction that there presented themselves, were of quite a different character. The large head of a male child, much advanced in ossification, was wedged in the deeply conical cavity of a perfectly unyielding pelvis. It was very difficult to apply the forceps; and when the attempt was made, the instrument became as impacted as the head.

* Chloroform in the practice of Midwifery, p. 6.

not be moved; and great injury was done to the passages. The obvious conclusion was against making such attempts, but rather to perforate the head, and extract with the crotchet as soon as the child ceased to exist. This could always be ascertained by the stethoscope, in sufficient time to operate before any symptoms dangerous to the mother presented themselves.

I was anxious, therefore, to ascertain whether such cases of impaction were frequent here; and whether, in this controversy about the forceps, the term "impaction" had precisely the same meaning as I had given to it. I soon found that this was not the case; that such instances were rare; but that the same degree of disproportion was produced in a manner altogether different. The pelvis was slightly distorted; the cavity presented the characters of the cordiform pelvis, in which the head was wedged, and might be called impacted; the ossification of the bones was not advanced more than usual, sometimes not so much so; the child was frequently a female; and if the constitution of the patient were strong, and the action of the uterus powerful, I have no doubt that the head would be forced through the pelvis by the natural efforts alone. *The case, however, always failed here: the habit was feeble, the pains weak, or, if vigorous, soon ceased to be so; and, as no advance was made perhaps for several hours, aid was called for. Were we to perforate in these cases of impaction, or to use the forceps? I came to the conclusion of adopting the latter course, and found it successful; so much so, that I think I have not performed the operation of perforation five times since I came to London. Time will not permit me to detail several of these cases, in which I delivered with the forceps. I shall, therefore, only select a few of the most striking.*

CASE IV. IMPACTION OF THE FETAL HEAD: FEEBLE UTERINE ACTION: DELIVERY BY PERFORATION IN FIRST LABOUR, AND OF LIVING CHILDREN BY FORCEPS IN TWO SUBSEQUENT ONES. In 1847, I was summoned to a lady, who had been nearly five days in labour of her first child. She had suffered great agony during that time; and when I saw her, the head was fixed in the pelvic cavity, the bones overlapping very much: the vagina was congested and tender, and the discharge from it very offensive. The child was evidently dead; and I agreed with the gentleman who called me in, that perforation alone could be performed. A putrid child, of a very large size, was thus delivered.

This lady became pregnant of her second child; and was attended by a different practitioner. On September 20th, 1849, labour commenced in the morning, with irregular but severe pains, which became more uniform towards night, but were not strong. Labour continued more regularly during the 21st. The pains ceased, however, on the morning of the 22nd; and there was no active labour during that day. Ergot of rye had been given without effect. In the evening, I was sent for. The head was tightly fixed in the cavity of the pelvis near the outlet; the ear could just be touched, but with great difficulty. I applied the forceps, and, in about half an hour, delivered a living girl, to the great joy of the mother, who supposed that, as before, the child must be destroyed.

In 1851, she requested my assistance for the third time, and engaged me especially for this confinement. Labour commenced on August 6th in the evening. She had the usual severe pains during the night, which, however, I controlled by chloroform; and about eight o'clock in the morning the head entered the pelvic cavity, where it remained until one in the afternoon. I waited thus for five hours, and finding no progress made, applied the forceps. The head gradually descended, and in about an hour a very large girl was delivered living.

In this case, the disproportion was in the cavity and outlet. Though slight in degree, it was sufficient to prevent delivery; because the action of the uterus was more powerful, the pains caused agony, and were very inefficient. In her first labour, the patient was four days suffering in this way, by which the progress of the labour was much interrupted; and at length the pains failed altogether, the child died, became putrid, and was so extracted. In

her second labour, she was two days suffering the severest pains, to no purpose; they ceased, and in the evening, I delivered her of a living child with the forceps. She would not then have chloroform; but in her third labour, the apprehension of her former sufferings, and the more favourable accounts that she heard about this anæsthetic, led her to wish for it. I gave it to her sufficiently to relieve the intensity of the pains, but not to remove consciousness. The labour proceeded most favourably. In about ten hours, the head descended into the pelvic cavity, from which it might have been at once removed. I waited, however, for five hours, in order to give the uterus fair play—a delay that I cared less about, because she did not suffer much pain during that labour.

CASE V. IMPACTION OF THE HEAD: DELIVERY BY FORCEPS: CHILD STILL-BORN. A few years ago, I was sent for by Mr. Griffith, of Greville Street, to see a lady, in labour of her first child. She had been in pain about forty-eight hours before I saw her. I found the head in the pelvic cavity, which it filled so completely, that the ear could not be felt. The bladder was fully distended, and the vagina very much congested; it was extremely hot and tender. The pains were active and regular. Finding matters in this condition, I was very unwilling to use the forceps then, and I would not destroy the child. It was agreed, therefore, to give the uterus a further trial, but to use means to prevent the increase of inflammation. The urine was drawn off, a cathartic enema administered, and other means used for this object. We met at night, and arranged to meet again the following morning at nine o'clock.

When I called, I found that no advance had been made. I therefore determined to remove the child, and at least to try the forceps for this purpose. The urine was again drawn off. There was great difficulty in applying the forceps; and, when they were applied, it was equally difficult to act with them. However, the head at length began to advance, to descend slowly on the perinæum, and was brought through. The child (a girl) was still-born; and every effort to establish respiration failed. It was unusually large, and the head was greatly compressed.

This lady recovered most favourably from the effects of this labour. She was soon able to be up and about; but just as the month concluded, I was urgently summoned to her, and found her dying, in consequence, I believe, of some violent and unexpected shock; but the cause of this change was then a mystery. There was no hæmorrhage, or other way of accounting for it; and, unfortunately, no *post mortem* examination was allowed.

This case resembled the most nearly the kind of impaction that I had been accustomed to. It differed, however, altogether in the general character of constitution and temperament. The lady had a fine delicate complexion, with small bones, and was in no way robust. She had much more the appearance which indicates a scrofulous diathesis, than that of rude health. I inferred, therefore, that the difficulty arose from slight disproportion in the pelvic cavity, which was sufficient to prevent the head of so large a child from making any advance, and produced impaction. Had she been delivered the night before, it is probable that the child would have been saved.

CASE VI. IMPACTION OF THE HEAD: DELIVERY BY FORCEPS: CHILD ALIVE. In February 1851, I was requested by Dr. Bowman, of Dalston, and Mr. Gill, of Islington, to see a lady who had been two days in labour of her first child. An obstetric physician had seen her early that morning; he would not then interfere, but gave it as his opinion that labour should be permitted to proceed for six hours longer; and if delivery did not then take place, the child should be removed by the crotchet. Other engagements prevented this gentleman from again seeing her; so I was sent for, and arrived about four o'clock in the afternoon. The case was very like that which I have just detailed. The head was fixed in the pelvic cavity very tightly; the ear could be felt, but not without difficulty; there was no great pressure on the urethra, neither was there any evidence of inflammation in the vagina: so far, therefore, the balance was in

favour of this patient. I stated to the gentlemen who consulted me, that I thought the child might be delivered by the forceps; and, as they agreed, I proceeded to the operation.

There was great difficulty, from want of space, in applying the pubic blade: it was at length placed over the ear of the child. The opposite blade was more easily introduced. When the instrument was fixed, the pains, which had ceased, returned with vigour; and, by acting with them, the child was delivered in half an hour. It did not at first inspire, but the heart was acting: by degrees, respiration was fully established, and the child saved. This lady recovered without any unfavourable symptoms.

These cases, to which I might add others of a similar character, convinced me that in these discussions about the comparative merits of the forceps and crotchet in difficult labours when the head was "impacted", we were not speaking of the same thing. When the head is impacted, because the pelvis is slightly distorted, the forceps may and should be used; but when the impaction is caused by the conical cavity of the masculine pelvis, it should be avoided. The former class of cases prevail here in a much greater degree than the latter; and, consequently, the operation of perforation should be very seldom performed. I have stated how it may be avoided in those cases, where it has been performed in consequence of want of space in the conjugate axis of the pelvis. I trust that I have now shewn that it may also (with these few exceptions) be avoided when the head is fixed in the pelvic cavity. If this be granted me, an important corollary follows this conclusion; viz., that delays under such circumstances are always dangerous. If I am obliged to perforate, I delay the operation as long as possible, to avoid destroying the child; but if I think that it can be saved, the sooner the mother is delivered, consistently with her safety, the better. Hence, as soon as the disproportion is ascertained, and three or four hours are allowed, in order to estimate the power of the uterus, the forceps may be used: a longer delay exposes the patient to all the risks of inflammation. In fact, many of the bad effects of forceps operations arise from having recourse to this aid far too late, when the passages are inflamed. The action of the uterus is suspended, because inflammation is commencing in the tissues; the head of the child is allowed to remain in the same position for ten, twelve, even twenty-four hours; at length, the forceps is applied, and produces perhaps a slough, and consequently a fistula; the perineum never escapes. Such unfortunate results might all be avoided by more timely interference.

These facts may also shew the importance of a more careful study of the peculiarities of the pelvis and their diagnostic characters. By this means only can we recognize the true character of the difficulty the moment it presents itself. I know of no other way of discriminating cases, which require aid, from those which may be left to themselves. To decide such a question by time alone, exposes the patient to all the risks to which allusion has been made. A previous knowledge of the cause of arrest is absolutely essential, in order to avoid unnecessary delay.

Henrietta Street, Cavendish Square, February 1858.

ILLUSTRATIONS OF DISEASES OF THE HEART AND AORTA.

By R. HUTCHINSON POWELL, M.D.

(Concluded from p. 206 of last number.)

II. ILLUSTRATIONS OF ANEURISMAL DISEASE.

AN extract taken from some manuscript notes of lectures delivered by Dr. Corrigan, of Dublin, in 1838-9, clearly, though very briefly, sums up the pathology, diagnosis, and principles of treatment of internal aneurismal diseases, as exhibited in the succeeding cases; and will prove interesting, from the close correspondence existing between the lecturer's *dicta* and the results of independent and varied observation. I am individually responsible for the correctness of the report.

"Aneurism of the aorta is divided into true and false. In the first variety, simple dilatation of its coats exists; in the second, ulceration takes place through the inner and middle coats, causing rupture; the latter variety is most frequently met with.

"Its pathology essentially consists of disease set up in the lining membrane, and subsequent deposition of lymph between it and the fibrous coat. The latter ultimately gives way, and the areolar tissue alone then forms the aneurismal sac; the opening from the aorta into the aneurism being mostly small. True aneurism is never cured when present at the mouth of the aorta; the blood being always fluid. In false aneurism, the process of cure consists in the deposition of lymph at that part of the sac which is most remote from the circulation. The lining membrane, which is ultimately formed by, and constitutes the innermost of the fibrous layers, becomes continuous with that of the aorta, and takes on the characters of serous membrane. No deposition of lymph ensues in true aneurism; hence, no reparation is effected, the blood continually circulating through the dilated aorta.

"As to the diagnostic symptoms of aneurism of the aorta, death may ensue without its detection previously. In ordinary cases, a pulsating tumour is observed to the right of the sternum, between the second and third ribs, on the right side of the aorta. Pulsation cannot be detected, if a quantity of coagulated blood intervenes. The pulsation may be rendered more evident by the aid of a prolonged lever; its movements being thus made more apparent, as from the increased movement of the leg in popliteal aneurism. There usually exist dulness on percussion, and absence of the normal respiratory murmur over the affected part of the chest. *Bruit de soufflet* may or may not be present. When organic disease exists in the chest, it is rendered more evident on the patient's "taking cold". The pulse is not to be depended upon. The negative symptoms of the non-existence of other thoracic diseases will much assist in the diagnosis. If the bellows-murmur be heard in aneurism of the aorta, the valves will be invariably found engaged, unless where the murmur arises from depletion. Aneurismal disease is especially indicated by the morbid sound being intense and circumscribed in a place in which it does not naturally exist in the course of the vessel.

"Aneurism of the abdominal aorta is marked by severe pain, intermittent in character: it is usually of the false variety. In thoracic aneurism, there is usually but little pain complained of. It is said that aneurism of the aorta produces hypertrophy of the heart; but it never does so, unless when obstruction or diseased valves exist.

"In abdominal aneurism, it is to be observed that the diagnosis is very difficult in the early stage: there are more violent neuralgic pains than in thoracic aneurism. In the erect or sitting posture, no bruit is detected by the stethoscope; but when the shoulders are placed lower than the hip, a loud bellows-murmur is then perceptible. It is a severe disease; and the patient is very liable to sudden death. In chronic enteritis, dyspepsia, and derangement of the nervous system, a bruit is occasionally heard, but along the entire abdominal aorta; the aneurismal murmur being circumscribed. Aneurism may be known from a tumour pressing upon the abdominal aorta, by the murmur not becoming inaudible or of less intensity on change of the supine or lateral posture; by the expansive and heaving motion of aneurism; by the constantly recurring and severe pain and bellows-murmur; by the immobility of the tumour; and by the history of the case. Coldness of the extremities is a common symptom, owing to the non-reception of the normal amount of blood, much of which is detained in the aneurismal sac.

"In the treatment of aneurism, the indications are: First, to promote the coagulation of the blood in the aneurismal sac, and thus to diminish the chance of rupture: this may be effected by moderate and repeated venesection, by the use of digitalis, spare diet, and by using but little liquid; the object being to cause the blood to possess a large amount of fibrin, so as to promote its coagulation in the sac.

Second, to relieve neuralgic pains involving the pleura, peritoneum, and the nervous trunks, by sedatives and by local bleeding, occasionally conjoined with the exhibition of mercury to touch slightly the gums. By these means, the inflammatory action, which is liable to arise in the coats of the sac, may be overcome. It should always be remembered, that the pulse in many cases is not a sufficient guide in the treatment, venesection often giving relief when the pulse cannot be felt at the wrist.* The abstraction of blood acts by emptying the sac, and lessening its pressure on adjacent parts. New aneurisms may form in the course of the aorta; those farthest removed from the heart being most likely to take on the reparative process."

CASE VI. TRUE ANEURISM AT THE ROOT OF THE AORTA. (Related by Mr. Oubr .) A married woman, 35 years of age, nine months advanced in pregnancy, was observed, half-an-hour after retiring to bed, to become speechless, though conscious. Death ensued one hour subsequently.

On *post mortem* inspection, the pericardium was found to contain about a pound of dark coagulated blood. The heart's tissue was rather flabby. The aorta was externally of a reddish hue, bulging at one part, and partially adherent to the serous envelope. The internal lining membrane was also reddened, and showed three points of ulceration, which had made way through the outer coats of the vessel, and had given rise to the fatal h morrhage. The abdominal organs were healthy, excepting the liver, which was slightly enlarged.

This is an instance of the absence of any direct diagnostic character of impending death, resulting from disorganization of the arterial tissues; no bruit, or other sign referrible to the heart or blood-vessels being complained of, or recognisable during life. The probable recurrence of incidental inflammation of the internal vascular coat in this as in other succeeding cases, serves to account for the giving way of the tissues, ulceration being a common sequence, and leading to a fatal issue from extravasation of blood.

CASE VII. ANEURISM OF THE AORTA THROUGH ITS ENTIRE COURSE. J. H., aged 45, a wheelwright of phthisical family, had, about seven years previous to coming under Dr. Hare's notice, fallen from a high loft, and cut his head. He had become emaciated, and had suffered from cough and expectoration for two years. His present symptoms were a sense of oppression when in the recumbent position, especially on the right side; cough, with some expectoration; dysphagia; hoarseness; short breath on exertion; pain in the right shoulder, and on the right side of the sternum; the tongue was furred; he had some thirst; pulse 95, small, easily compressed. A tumour existed between the first and second ribs, close to the right border of the sternum. It was circular in shape, two inches in diameter, and projected from a quarter to half an inch from the chest. Pulsation was very strong, the parietes feeling thin. There was no murmur, but the sounds of the heart were distinct. Auscultation and percussion of the chest indicated some solidity of the lungs, especially the right.

A month subsequently, the patient had an attack of dyspnoea, and inability to swallow, with lividity of the face and hands. The pulse was 100, full. He was relieved by a small bleeding, together with a mixture of digitalis and nitre (previously in use), conjoined with ipecacuanha and squilla. The tumour subsequently diminished in size, so that in three months there was merely a slight prominence, and its diameter was reduced to half its former size, with proportional diminution of pulsation. The man became gradually weaker, now suffering, in addition to his other symptoms, from giddiness, irregular pain in the chest, and occasional partial syncope. The left hand and arm had lately become oedematous. He died without a struggle, six months after coming under observation.

A *post mortem* examination revealed tuberculated and excavated lungs. The heart was large; the mitral and aortic valves were thickened, but smooth. Copious deposition of cartilage and bone was found in the lining membrane of the aorta. The aneurism arose from the superior surface of the arch of the aorta, close to the arteria innominate; it was globular in shape, and was filled with large coagula. Besides displacing some large vessels in the vicinity, it had produced absorption of a small portion of the sternum, flattening of the trachea, with slight ulceration, and partial absorption of some of its cartilages. Another small aneurism was found, commencing at the under part of the aorta, at the point of junction of the arch with the descending portion of the vessel; two small bulgings appeared on the anterior aspect of the arch.

CASE VIII. STERNAL TUMOUR SIMULATING ANEURISM OF THE AORTA. (Mr. A. Anderson.) A woman, aged 59, had been under treatment, with little relief, five years previous to her death, for pains at the top of the sternum, supposed to be neuralgic or rheumatismal. Two and a half years subsequently, a small pulsating tumour was observed over the site of the former pain. It was very tender on slight pressure. It increased in size, to the right and left of the summit of the sternum; the tenderness becoming aggravated. Acute pain was felt, six months prior to death, in the lower extremity as far as the knee. She had had slight h moptysis on two or three occasions. The tumour followed the respiratory movements; and a bellows-murmur existed over the swelling.

On *post mortem* examination, the heart and arteries were found almost healthy. The calcareous matter of the sternum had nearly disappeared, the bone enclosing, instead, a fibrous encysted mass, about two and a half inches in antero-posterior diameter, which pressed upon the aorta.

CASE IX. TRUE THORACIC ANEURISM OF THE DESCENDING AORTA NOT RECOGNISABLE DURING LIFE: DEATH FROM SECONDARY H MOPTYSIS. (Dr. A. T. Thomson.) W. W., of weakly constitution, suffering occasionally from h moptysis and dyspnoea, was emaciated on coming under Dr. A. T. Thomson's observation. The pulse was 84; the heart's sounds normal; coarse respiration was heard throughout the right side of the chest; the breath-sound was defective at the summit of the left lung, over which there existed dulness on percussion. Purgatives and gallic acid were given. On the second day, he had copious h moptysis. The other symptoms persisting, he was bled. The blood was neither buffed nor cupped. Gallic acid was continued. On the third day, he had further h moptysis. Venesection was repeated to eight ounces. On the fourth day, there was still greater h moptysis. Refrigerants were substituted for gallic acid. On the sixth day, there was subcrepitant rhonchus under the left clavicle. On the seventh day, he had further frothy h morrhage, followed by some mitigation of the general symptoms. On the ninth day, he was dry-cupped, and bled to twelve ounces. Up to this time, the pulse had increased in force and frequency; acetate of lead was now administered. On the twelfth day, all the symptoms wore a less promising aspect, with nocturnal delirium. Pulse 120, irregular; tongue dry; rusty and scanty expectoration; much dyspnoea, anxiety, and jactitation. Wine, beef-tea, and carbonate of ammonia in decoction of Peruvian bark, were given. On the thirteenth day, dyspnoea was very urgent; the physical signs indicated pneumonia. Death ensued at five p.m.

Post mortem appearances. The right lung was congested, and further advanced in inflammatory change. The bronchial membrane was deeply injected; a few tubercles were visible. The upper lobe of the left lung was very firm, and resistant to the knife: its section was of a brownish red colour, and, under the microscope, showed exudation corpuscles, which were not present in the lower lobes; the middle and lower lobes contained patches of extravasated blood, of varying size. The bronchus, where it passed under the arch of the aorta, was not affected. The pulmonary veins, to their minute ramifications, were filled with a dense dark coagulum. The chief bronchi were compressed by an

* An instructive case is given in the *Lancet* (March 27th, 1852), under Dr. Addison's care, in Guy's Hospital, in which the pulse of the left radial artery from being feeble, ultimately became nearly imperceptible. This was (*post mortem*) traced to obliteration of the left subclavian artery from the pressure of an aneurismal tumour in the arch of the aorta.

aneurismal tumour, formed by the entire arch of the aorta ; its ascending portion, one inch from the valves, being also dilated ; and about one inch and a half from the origin of the left subclavian artery, a tumour, of the size of a small apple, was seen. The internal coat of the arch, and that of the aneurism, were studded with a calcareous and atheromatous deposit ; the latter was determined by the microscope to consist of cholesterine and oily matter. The aneurismal tumour was formed by uniform dilatation of the aortic coats. The heart was healthy, excepting an atheromatous deposit upon the aortic valves.

This case is suggestive of many reflections. All the symptoms were readily referrible to tubercular disease and its effects. No bruit was audible, in consequence of the comparatively normal condition of the aortic valves ; and the signs usually present in posterior thoracic aneurism were absent, from the tumour just clearing, and not compressing, neighbouring organs. Continuous pulmonary congestion would probably serve to excite suspicion as to the existence of this disease, in the absence of more positive signs, as the buffed appearance of the blood ; which latter sign, though absent in this case, most likely from the cachectic condition of the patient, usually exists in states of the circulatory apparatus leading to aneurism.

CASE X. RUPTURE OF THE DESCENDING AORTA, WITH TRACES OF INFLAMMATORY ACTION. (By Dr. Campbell). A carpenter, stout in person, aged 38, complained of deep-seated pain in the left chest on inspiration, with dyspnoea, especially at night, and when in the horizontal position. Pulse 80, hard and small ; no palpitation existed. He was blistered, and took tartarised antimony, with relief to his symptoms, the pain being relieved by stimulants. He was found dead by his wife about midnight.

On *post mortem* inspection, the heart was seen to be quite healthy, as were the other viscera of the thorax and abdomen. The posterior mediastinum was torn on the left side, the corresponding pleural sac being filled with blood. The arterial tube was ruptured in various directions, not being enlarged or dilated, but thickened, and having a slight blush of redness, and having its coats infiltrated with atheromatous deposit, from the origin to the seat of rupture.

The order of events in this instance, and in some of the preceding cases, would appear to have been slow abnormal change in the arterial fibrous tissue ; and subsequently, inflammatory action in the internal serous or epithelial lining, terminating in ulceration and fatal extravasation.

CASE XI. TRUE ANEURISM OF THE DESCENDING THORACIC AORTA. (By Mr. Forbes.) The subject was a gentleman, aged 53, previously in good health, and of robust constitution, who had complained, five years before death, of severe dyspeptic symptoms, præcordial pain, emaciation, and great sensibility to cold. No physical signs existed, prior to death, indicative of pulmonary, cardiac, or other thoracic affection ; there being neither cough, dyspnoea, abnormal percussion, nor respiratory or cardiac murmurs.

On *post mortem* inspection, there was found a small basinful of nearly coagulated blood. The lungs, pleura, heart, and its valves, were quite healthy. The escape of blood was traced to an orifice close to the spinal column, connected with a rent in the descending thoracic aorta, nearly three inches below the arch ; it had there become dilated into a pouch, which had contracted adhesions to the anterior aspect of one or two of the dorsal vertebræ, and at this part the sac had given way. No fibrous laminæ or coagula lined the sac, but its coats were ulcerated, and nearly perforated in various directions, and the pressure exerted on the vertebræ had caused their absorption to a considerable depth. The ascending portion of the aorta was similarly diseased in its coats, though in a less degree, and was considerably dilated. The abdominal viscera were healthy, excepting the presence of a slight blush in the large curvature of the stomach.

This case is discouraging to the diagnostician ; as not a single *direct* sign or symptom existed which would serve as an index to the formidable disease, insidiously progressing

towards a fatal issue. The præcordial pain was naturally referred to the dyspeptic disorder, there being no physical evidence of cardiac or aneurismal disease present. In similar instances, the persistence and severity of the functional disturbance should excite suspicion, especially if *great sensibility to cold* be present in subjects otherwise in good condition, and free from thoracic or nervous disorder. The indirect method of excluding all other morbid states, may further throw some light on this obscure disease. It will be observed that, in the above case, as pressure was not exerted on the thoracic contents, excepting the dorsal vertebræ, so the corresponding symptoms were absent ; and no murmur was audible, as the aortic valves were unaffected.

CASE XII. ABDOMINAL (TRUE) ANEURISM. The case (under Dr. Stroud's care) was that of a smith, who applied with an epigastric tumour, with impulse, but no sound. Some narcotics were prescribed, to relieve a severe pain complained of about the crista ili, but not in the vertebræ. The man died suddenly, in University College Hospital.

A *post mortem* examination showed an abdominal extravasation of twenty-one ounces of coagulated blood, and forty-eight ounces of serum. The tumour was of the size of the closed hand, and was bounded posteriorly by the vertebral column. The sac firmly adhered to the duodenum, and thus accounted for obstinate alvine obstruction which had existed. Some coloured fibrinous clots were seen in the interior of the sac, and a rent was found of the size of a halfpenny. The dilatation of the artery had begun about two inches below the origin of the renal arteries.

CASE XIII. ABDOMINAL (DIFFUSED FALSE) ANEURISM. (By Mr. Obré.) The subject was a policeman, aged 45. He had formerly suffered from cholera in India, and was a man of resolute character. Three years before his death, he was knocked down, and kicked in the loins, and eighteen weeks ago he was doubled back across a balustrade. He subsequently suffered much from pain in the loins and abdomen. He constantly had to lie down, leaning towards the left side, and was obliged to discontinue his occupation. He had constipated bowels, cough, etc. A tumour was detected, three weeks before death, to the left of the spine, and over the eleventh rib, just underneath the inferior angle of the scapula. It was soft and elastic, about three inches and three quarters in length, by two and a half inches in apparent breadth. The eleventh and twelfth ribs were perforated quite through. The impulse of the tumour, synchronous with that of the heart and the pulse, was inconsiderable, except towards the centre. The tumour probably progressed rapidly just prior to death. No murmur was audible anteriorly or posteriorly. Death suddenly occurred while he was sitting up in bed, and conversing with his wife.

On *post mortem* inspection, the body was found emaciated, the left side of the thorax filled with blood (the bulk of two closed hands), and serum (two quarts). The diaphragm was seen bulging upwards, its fibres being split, and enclosing a clot of blood. The heart was small, and surrounded with fat. The arch of the aorta contained a deposit, consisting of cholesterine and fat. Some effused blood was detected in the descending aorta, where it passes through the diaphragm ; the coats of the vessel were ruptured to an inch and a half in extent, giving rise to the formation of an aneurismal tumour. Laminæ existed on the right side, and clots of blood on the left. The tumour had pushed the diaphragm upwards, its coats being partially derived from that muscle. Its circumference was about twenty inches ; its coats being an internal fibro-cellular layer, and the diaphragm and pleura externally. The body of the eleventh dorsal vertebra, and the heads of the eleventh and twelfth ribs, were absorbed ; thus leaving the tumour with but a muscular and tegumentary covering, no fibrous coats existing posteriorly. The abdominal aorta below the rent exhibited bony plates on its internal surface.

It is obvious that any accident would peculiarly tend to rupture a vessel thus predisposed to disease in its coats conjointly with the exciting nature of the man's occupation, and strongly acting circulatory apparatus.

diagnosis was rendered peculiarly difficult, from the tumour being posterior to the diaphragm. No murmur was audible in the tumour, as no blood-current existed therein, nor was there any bruit heard in the abdominal aorta, there being no pressure or other condition productive of murmur, in the calibre or contents of the tube, as was evidenced by the absence of œdema or venous obstruction. The ascending vena cava lay over the aneurismal swelling, but this did not apparently retard its circulation; the pressure of the tumour was directed towards the exterior of the body, and there exhausted.

In the absence of direct signs of cardiac or aneurismal disease, the diagnosis must be guided by collateral circumstances, and by those symptoms which arise from functional derangement in adjacent or related organs or structures. With reference to the former (indirect) source, it is peculiarly significant to note the occupation of most of the above subjects, as implying much and strenuous bodily exertion, prompted by a sanguineous temperament, and, in some cases, great mental excitement or anxiety. As regards functional derangement, this will depend upon the anatomical or physiological relations; œdema, lividity, vertigo, dyspnoea, etc., may or may not exist, according to the interference with, or freedom from pressure on the adjacent structures. The more or less intermittent character of pain or other functional disturbance, is worth observing in these sometimes profoundly obscure cases; the symptoms being for the most part paroxysmal, probably arising from varying conditions of blood-pressure, or other perturbations. Their aggravation at night, and in the recumbent posture, is very characteristic. The contents of the stomach and intestines exert a certain amount of pressure on the arterial tube, sufficient to decide its rupture, in its diseased and weakened state. The sudden and quiescent dissolution of individuals suffering from cardiac or aneurismal disease, is a conspicuous occurrence in such cases. In those cases but little complicated with other structural disease, death took place at night, and in the absence of all excitement. It is probable that the vascular apparatus is unusually loaded and strained at this period, both from this posture favouring accumulation and obstruction, and from the tendency to vascular repletion induced by the abeyance or diminution of functional activity in other organs. This diagnostic mark is of less value in cases associated with disease of the lungs, etc., in which death ensues in a more gradual and less unexpected manner, in consequence of the progressive wearing out of the system, and general loss of power.

In some, if not all, of the preceding cases of aneurismal disease, the blood probably abounded in fibrin, death occurring in one of them (Case VI) in an advanced stage of gestation. This function, it is well known, is attended with a buffed condition of the blood, and in other ways favours the operation of the more immediate causes productive of aneurismal or cardiac affections. In many of these cases, either fibrin, fat, cholesterine, or calcareous salts, more or less conjointly or separately, were found incrusting or replacing the normal tissues; thus indicating a disturbance of the balance obtaining in the healthy nutrition of the organism. Some showed evident traces of inflammation, and others exhibited aberrations of structure less evidently connected with the latter operation, though not the less arising out of malassimilation and loss of equilibrium in the blood-constituents. Of what cases either of these metamorphoses may be respectively predicated, it is impossible at present to affirm with any degree of precision; but a careful collation of all concomitant symptoms, with reference to age, sex, temperament, habit of body, etc., may enable the practitioner to assume, with some probability, the presence and nature of structural disease existing in the heart or blood-vessels.

The preceding cases, though the remarks appended have been of necessity disjointed and inconclusive, have served the purpose of bringing under observation some important subjects involved in the nature, diagnosis, and treatment of cardiac and aneurismal diseases. An extensive collection of similar cases will be required in laying

the foundation of a goodly and unassailable superstructure; so that trustworthy data as to the variation of symptoms corresponding with the site and character of the morbid change may be at length acquired, and acted upon in the diagnosis and treatment of these formidable affections.

21, Edwards Street, Portman Square, February 1854.

ON THE TREATMENT OF DIARRHŒA BY DILUTE SULPHURIC ACID.

By EDGAR SHEPPARD, Esq.

THE prevalence of diarrhœa at this unusual season of the year, in the locality where I reside, leads me to record a few additional cases illustrative of the success of the treatment by dilute sulphuric acid. In the last volume of the *Provincial Medical and Surgical Journal*, (No. 19, p. 471), I had the honour of submitting to the profession some remarks upon this subject; and the cases which I then detailed went far to prove, that when used with judgment and discretion, there is no remedy which can in any disease act more rapidly, or produce more strikingly beneficial effects, than the mineral acid above alluded to, in this common form of bowel affection to which we attach the term diarrhœa. And with respect to this treatment it may be further observed, that the profession has been almost unanimous in assenting to its advantages and benefits. Mr. Rogers of Plymouth* tried it, and came to the conclusion that difference of locality might produce a different type of disease, requiring an essentially different treatment. His cases would not yield to—nay, they were rendered worse by—the acid. This was the only exception to the efficacy of the dilute acid of which I have been enabled to hear. It indeed seemed nothing more than another testimony to the truth of there being distinctive characters, and essentially varying forms, of every disease, prevailing in different localities at one and the same time. Another gentleman, however, practising in the same town, was most successful with the acid, and gave the strongest evidence of its beneficial and rapid action. I thought that Mr. Rogers's doses were too small, and not exhibited with sufficient frequency; but he tried what I suggested (half-drachm doses) with an equal want of success.

How are we to account for this contradictory evidence? Was the acid of one practitioner harmless and inert; or were all the cases which one practitioner met with of that type which would only be aggravated by an acid treatment? The description of Mr. Rogers's cases would not lead to this latter conclusion; the former alone seems to yield the proper solution of such discrepancy in the results. But, be that as it may, Mr. Rogers stood almost, if not quite alone, in the conclusions to which he came as to the inefficacy of sulphuric acid. I proceed now to detail a few cases.

CASE I. J. P., for three seasons had been incessantly troubled with diarrhœa in the hot summer months. He usually applied then, as often as once a fortnight; relief for that short period being afforded—and that often with great difficulty—by chalk, opium, and astringents. When the diarrhœa proved more obstinate than usual, carbonate of soda and chlorate of potash were resorted to. A dry and furred tongue, with constipation and great flatulence, was always the ultimate result of the above treatment.

Last season he first applied in June, with the old train of symptoms; and I gave him the dilute sulphuric acid in half-drachm doses, with compound tincture of cardamoms and sugar. He was directed to call on me again the next day, if he was no better. He did not call; and therefore I could not report his case in my first paper upon the subject. Indeed, I never saw him after that period, until about six weeks ago, when, having chopped off one of his fingers with an axe, he was again brought under my observation. On my making inquiries touching his usual malady, he said that he had never had a day's illness since the "nice sharp"

* See last vol. of *Med. Times and Gazette*, No. 124.

medicine which I gave him in the summer. This is the most marked case I have ever seen, for the man was a perfect martyr (I had known him as such for three years and a-half) to diarrhoea, dyspepsia, and hypochondriasis.

CASE II. W. G., a strong healthy-looking man, but often afflicted with diarrhoea, applied on February 5th. He complained of constant pain in the bowels; great flatulence; thirst; and incessant purging; the stools being watery and colourless. Two doses of the acid effected a perfect cure. On February 27th he applied again: the same treatment was employed, with the same results.

CASE III. F. W., a delicate-looking, unhealthy individual, applied for relief. He had griping pains; great distension of the bowels; a white creamy tongue, with red edges; and profuse watery and colourless dejections. He was relieved by three doses of the acid.

CASE IV. Last week I determined to try the effect of this remedy in that form of diarrhoea, which is beyond all others so difficult to arrest, because usually dependent on different and much more serious causes—that of the last stage of phthisis. No benefit had been obtained latterly from the ordinary astringents, with chalk and opium; and but very slight and temporary from the combination of trinitrate of bismuth, and powdered acacia, suggested by Dr. Theophilus Thompson. Extract of logwood, rhatany root, and sulphate of copper, were also tried in vain. Dr. Cotton, in his recent valuable monograph upon *Consumption*, says, speaking of the acid, “for the advanced stages it cannot, I think, be trusted; in one or two instances I found it did some good, but in others it evidently aggravated the symptoms. The very circumstance that phthisical diarrhoea frequently comes on at the time when sulphuric acid is being taken to check perspiration or hæmoptysis, shows that, however useful it may be in some of the simple forms of diarrhoea, we have little to expect from it in consumptive cases.” (p. 227.) An additional inducement was offered me here to try the effects of the acid, in the circumstance of my patient, never having tried it for the symptoms so common in phthisis, for which it is generally resorted to. There had been an entire absence of perspirations from the beginning to the end of this case. The mouth was studded with aphthous sores, which necessitated the exhibition of the acid through a quill. The purging had not ceased for three days previous to this trial, a dejection taking place about every two hours. It was now arrested for twelve hours, by one dose. It then returned, and one more dose was given, but with no benefit. The last struggles of mortality were at hand; but I am content to think that this remedy did give some ease and comfort for a brief period, and so soothe the passage of my poor patient, and help to “lead her gently out of Vanity Fair”.

CASE V. Mrs. R. H., who had been confined three months previously, and was much reduced by nursing, was seized, on March 1st, with violent pains in the bowels, great relaxation and slight sickness. Two doses of the acid arrested the purging. The infant was not griped, although the mother continued to suckle it. Doses of five grains, thrice daily, of the citrate of quinine and iron have completely restored Mrs. H.’s health.

Upon what the diarrhoea which has recently obtained here is dependent, unless it be upon the wet and sodden state of the country, I do not pretend to determine. Is it prevailing elsewhere? It differs from the summer cases in there being much less thirst, and rather less pain. In fact, the general disturbance is not so great. It is equally amenable to treatment by dilute sulphuric acid; as, I trust, the foregoing cases have demonstrated.

Enfield, March 9, 1853.

IS HYPOSPADIAS A BAR TO MARRIAGE?

By DANIEL NOBLE, Esq.

SOME years ago, I was consulted by a gentleman, of high education and great intelligence, as to the propriety of his marriage. He laboured under that defect of the generative

organs called *hypospadias*; that is to say, the penis, which was short, was wholly imperforate; and the urethral opening was precisely at the point of junction between the scrotum and the inferior aspect of the organ. I informed him that he might marry; but that offspring, though not impossible, was improbable.

He married accordingly, about four years and a half ago. No signs of conception followed until last summer; and, a few days ago, the wife gave birth to twins, a son and a daughter. They were fine children, and alive.

As the individual cases of this description are generally of an embarrassing nature to the practitioner when consulted, I have thought it right to put this instance upon record.

For obvious reasons, I avoid names, and any address that might risk the slightest indication of the parties referred to.

Manchester, March 6th, 1853.

BIBLIOGRAPHICAL NOTICES.

ASYLUMS FOR THE INSANE. OBSERVATIONS UPON THE IMPORTANCE OF ESTABLISHING PUBLIC HOSPITALS FOR THE INSANE OF THE MIDDLE AND HIGHER CLASSES, etc. By THOMAS DICKSON, L.R.C.S.E., Resident Medical Superintendent of the Manchester Lunatic Hospital. pp. 62. London: 1852.

THE LUNACY QUESTION; OR, THE LUNATIC BENEFITED AND PROTECTED: with an Inquiry into Public and Private Asylums. By JOSEPH WILLIAMS, M.D., etc. pp. 48. London: 1852.

THE object of these pamphlets is to advocate the proposition, that *all* lunatics should be confided to the care of government. The vicious principles upon which existing arrangements for the isolation of the affluent insane are founded; the extinction of private asylums; and the amalgamation of the laws affecting the sequestration, detention, treatment, and inspection, of all classes of the insane, are a few of the objects aimed at in this sweeping measure.

Dr. DICKSON recommends his views by endeavouring to identify the treatment of mental disease in private establishments with “commercial enterprise”, and with such selfish and sordid motives as pecuniary dishonesty, “continued detention of those eligible by convalescence to trial, at least, in society”, and accessibility “to the interested suggestions of nominal friends”. He cites the abuses and atrocities disclosed by the parliamentary inquiries of 1815, which, it must be noted, applied to public as well as private asylums; together with instances of maltreatment, mismanagement, and unjust seclusion, detected by the Commissioners in Lunacy of late years, as inexpugnable arguments for saving the rich insane “from the evils they have long suffered through the rapacity and unscrupulousness of proprietors of private asylums”, whose “interest it is to *obtain* and *retain* the insane and the alleged insane, the curable and the incurable, and, maintaining their bodily health, to hurry them through the several gradations of mental disease, till imbecility ultimately accrues”. In the last place, he enters into calculations to show that the expense of fifteen public hospitals, constructed, furnished, and maintained, for the express purpose of suitably accommodating the higher classes, would be more than met by the funds at present appropriated for the benefit of the proprietor, rather than for the support of the patient.

Dr. WILLIAMS has a mortal quarrel with certain medical critics; but into this we do not feel it to be our duty to enter, further than to remark that, though he may have had some grounds of complaint, the bitterness of his retort impairs the force of his argument.

Dr. Williams’s thesis is, that “government should assume a more direct control over the medical officers both of public and private asylums”; and that the latter should be “done away with”.

In discussing this, however, he condemns as inexpedient "the removal of incipient cases of insanity of every kind to an asylum", but especially those of puerperal insanity, of delirium after fever, or of moral insanity, even when the patients belong to indigent families. His objections to seclusion are of various kinds; but may be resolved into the superior advantages of treatment at home; the evil effects of association with other forms of mental disease, as illustrated in the frequent alienation of nurses and attendants (which is apocryphal); the fact that lunatics are made objects of profit; and lastly, the illegalities and irregularities which have been shown, and may be suspected to exist, in receptacles for the insane. He conceives that a board of £1000 per annum is a temptation to detain a patient after the mental faculties have been restored.

We are not prepared to deny that certain benefits—particularly constant and long-continued scientific observation, and enlightened medical and moral treatment—might be more effectually secured by placing the insane of the noble and affluent classes in public asylums. But it is sound policy to agitate such changes only as are practicable. The compulsory seclusion of patients belonging to the higher classes in government or public asylums, is so totally inconsistent with our social condition, our prejudices, even with many of the feelings which lean to virtue's side, and with our notions of freedom, that such a project, however philanthropical, must be pronounced to be visionary. But were such obstacles swept away, it is very doubtful whether a public asylum is best suited for *all* forms of alienation; whether the guarantee afforded by publicity is to be preferred to the tranquillity and repose of privacy; whether, in fact, the features of a home, which may be given to a retreat for a small group, but which are scarcely compatible with the regulation of a large community, may not prove a direct instrument of restoration. We differ from Dr. Williams as to the efficacy or possibility of the cure of the insane at home; we pronounce such a course scarcely attainable to the wealthy, impracticable even to those of moderate means, and a mere self-delusion wherever attempted. Under it, all remedial measures are frustrated; moral influences are devolved upon servants; and imminent perils are momentarily encountered. But we are not blind to the existence of certain drawbacks and disadvantages which are inseparable from public asylums. They are, in general, we believe, conducted upon a system of large benevolence and sound science; but still *it is a system*, and therefore, to a certain extent, excludes the individualization of treatment. They must be governed by rules and rigid discipline; *they cannot form families*, cemented together by mutual dependence and affection. It has long been obvious to practical men, that while the great majority of cases of derangement are not only adapted for public asylums, but cannot be judiciously treated elsewhere, there is a certain proportion which may derive benefit from a different arrangement, and that it is the office of true wisdom and humanity to distinguish these classes, and to apportion to each that destination best calculated to effect amelioration and to secure happiness.

That the proprietors of private asylums derive profit from the misfortunes of their charges, is sufficiently obvious; but so do the physicians who attend such patients in their homes; and it is, to say the least, a gratuitous assumption that, *in general*, either the one or the other would prostitute his responsibilities in the manner so often and so broadly suggested. If the Reports of the Commissioners in Lunacy be appealed to, as evidence of the existence of abuses, such documents likewise show how few these are, and by how many advantages they are counterbalanced. It is no argument to say that Equirol was, and Conolly is, the proprietor of a private asylum; but it does bear closely upon the subject, that a large number of the class to which they belong, and of which it is desirable that they should be the types, are educated medical men.

That irresponsibility engenders neglect and deviation from duty, is axiomatic; but this may be removed by searching and constant inspection; by the limitation of the

license to medical or properly qualified men; and by the publication of the results of treatment; without annihilating a provision which is consonant with existing opinion, and has produced such splendid illustrations of its capabilities, as Brislington, Ivry, and Varines.

Drs. Dickson and Williams have performed what they esteem a public duty, fearlessly and faithfully; and while we recommend to them a more favourable estimate of the motives of their professional brethren, we feel that they are entitled to a candid hearing for having conscientiously discharged what they must have felt to be an ungracious task.

SANITARY MEASURES AND THEIR RESULTS; being a Sequel to "THE HISTORY OF CHOLERA IN EXETER, in 1832." By THOMAS SHAPTER, M.D., Physician to the Devon and Exeter Hospital, etc. pp. 32. London: 1853.

DR. SHAPTER is well known to the profession as an earnest sanitary reformer; and although he with true modesty keeps out of sight his own personal merits in the great work in which he has been so long engaged in the city of Exeter, we can have no hesitation in giving him a large meed of praise for the results which his present pamphlet lays before us. It is indeed a source of honour to our ASSOCIATION, that foremost in the work of sanitary reform we should number so many members, thus carrying on their divine mission; and we can almost envy the man who, like Dr. Shapter, has the fearlessness to overcome the prejudices of the people, the ability to carry on the work, and the satisfaction to see its result in a decreased mortality, a more healthy locality, and a more salubrious atmosphere. The work is written, as the author informs us in his preface, solely with a view to place in a clear and strong light, a very striking instance of the public benefit derived from the adoption of judicious sanitary measures.

"On the first occurrence of the Asiatic cholera in 1832, Exeter, in common with London, Bristol, and Plymouth, experienced a large amount of mortality; on the recurrence of the pestilence in 1849, London and Bristol suffered more than, and Plymouth as severely as, on the former occasion; while Exeter escaped with only a very small amount of disease and death." (p. 7.)

Let us proceed with Dr. Shapter, and see how he accounts for this satisfactory result. In the year 1832, the cholera in Exeter attacked the most unhealthy localities, where the houses were badly ventilated, undrained, and but scantily supplied with wholesome water. Between that year and 1849, Dr. Shapter was steadily engaged, in conjunction with his medical brethren, in convincing the citizens that many of the causes of the pestilence were of a preventable nature; and the hope expressed by him in his "History of the Cholera in Exeter in 1832", was realised in every particular.

The disease in 1832 found Exeter having a dense population of 28,000 persons, occupying old houses, with an airy suburb; the streets of this city were generally narrow, with numerous courts and alleys; the roads had gutters in their centres in nearly every street, and formed the only means by which the sewage was removed, there being no plan of general drainage; the supply of water was small and difficult to be procured. Here, indeed, was a focus of pestilence! But this was not all: the houses of the poorer districts were overcrowded, amidst slaughter-houses and pig-styes, with cellars filled with poultry and dunghoops everywhere: while the scavengers' visits took place but once a-week. Can it be wondered at, that with this condition of things, the cholera should have destroyed, between the 19th July and the 19th October 1832, four hundred and two persons, while one hundred and forty-two deaths took place during that period from other causes? The mortality, too, was distributed among the four parishes, out of the twenty which comprise the city, which "were precisely those characterized by bad drainage, and a generally ill-cared for and unwholesome state."

Turning to the second period of the inquiry, Dr. Shapter

finds that, on the recurrence of the cholera in 1849, Exeter had a population of 31,212, and that the total deaths from cholera and diarrhoea, from the 19th July to October 29th, during which the epidemic prevailed, amounted to *forty-three only*. Of this number the very large proportion of twenty-six occurred in the lower portions of the city, near the streams which there traverse it, or else resided in houses conspicuously filthy, and "offering those conditions which usually predispose to malignant and fatal disease."

We now come to account for this marked change in the mortality. Immediately after 1832, active means were taken by the water-company to increase the supply: the commissioners established a perfect system of underground drainage, and removed several courts and old houses, so as to secure the permeation of free and wholesome air. In 1847, when the attention of the public bodies was called to the progress of the cholera westward, extensive operations took place; parochial committees were formed for household visitation, so that many objectionable nuisances were removed; handbills were distributed calling attention to the provisions of the "Health of Towns Act", which was speedily put in force; and, in October 1848, a Board of Health entered upon active duty, having for its chairman Dr. Shapter himself; this board sat weekly, and were assisted by an efficient staff of medical and other officers; the markets were closely watched, and all offensive provisions destroyed whenever detected.

"The immediate and very evident effect was the marked diminution in the former amount of diffused sickness, more especially of fever, which had been previously the almost constant occupant of the lower parts of the city." (p. 13.)

In 1849, the city was portioned into ten districts, with a medical officer over each, medicines free of cost were supplied, lists of nurses kept, temporary hospitals and houses of refuge provided, and a handbill issued suggesting precautionary measures. Dr. Shapter's anticipations were singularly correct; the pestilence was mitigated, so that the services of the medical attendants of two districts only were required.

"The total deaths from cholera, in Exeter, in the two epidemics of 1832 and 1849, amounted to four hundred and forty-five. Of these four hundred and two, or ninety per cent., took place with the concomitants of bad drainage and a deficient water supply; while, with in great measure an absence of these conditions, the complementary number of forty-three, or ten per cent. only occurred. Can any more convincing statement be adduced of the beneficial influence of sanitary improvements?" (p. 14.)

Our limits will not permit us to follow Dr. Shapter in his very interesting appendices. One point, however, calls for our especial notice, viz., that this vast amount of public good could not have been obtained without the cordial, anxious, and energetic assistance of the medical superintendents of districts; and that, nevertheless, when the pestilence had subsided, and Dr. Shapter, as chairman of the sanitary commission, drew up a report "on the services of the medical officers of the sanitary commission", recommending to the corporation that a sum of not less than £50, should be presented to each of these gentlemen, "the recommendation was not complied with to its full extent." How long will the profession thus minister, at the bidding of an ungrateful public, to the wants of those who are sick and dying, from pestilences which may not spare themselves; and persevere in their endeavours to mitigate diseases, from the hazardous and engrossing attendance on which they are not allowed to derive any portion of their daily bread? How many, alas! of those who risk their lives and consume their days amidst destructive epidemics, receive no other remuneration of their labours than the reward of a good conscience.

DISEASES OF THE HUMAN HAIR: from the French of M. CAZENAVE. With a description of an apparatus for FUMIGATING THE SCALP. By T. H. BURGESS, M.D. 12mo. London: 1851.

This is a very useful little treatise, and its perusal is well calculated to disabuse the public of the ridiculous heresies which are so common regarding the management of the hair. The description of Dr. Burgess' apparatus for fumigating the scalp is very interesting.

After an account of the general causes which induce baldness, we find the following observations, which, though not new, are so true, and yet so entirely lost sight of by all of us—doctors and patients alike—that we cannot help quoting them.

COVERINGS FOR THE HEAD. "The heavy covering for the head to which men have been doomed, is an unfailing cause of injury to the hair. Even at the present day, *the hat*, by its weight, impermeability, and the pressure which it occasions round the head, materially assists in the premature destruction of the hair. M. Rostan entertains a similar opinion. He considers that the caloric accumulated between the hat and the surface of the head, and also the rarification of the air, which is like that of a stove, exercise an injurious influence upon the hair itself. M. Prècy, in an interesting thesis, insists upon the truth of this. He says that this pressure, in proportion to its force, will have the effect of diminishing the circulation of the parts, and consequently the nutrition of the hair, which then becomes easily detached, and falls off. In support of this view, he remarks that valets, footmen, etc., who remain a great part of the day with the head uncovered, preserve for a long time a copious supply of thick hair; and that soldiers, who are obliged constantly to wear heavy caps and helmets, very soon become bald." (P. 75.)

HYSTERICAL AND NERVOUS AFFECTIONS OF WOMEN. By WILLIAM JOHN ANDERSON, F.R.C.S. 8vo. pp. 39. London: 1853.

This is a slight popular sketch of some of the more common forms of hysteria.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

IS THE ARCUS SENILIS DIAGNOSTIC OF FATTY DEGENERATION OF THE HEART?

IN 1850, Mr. EDWIN CANTON demonstrated to the Medical Society of London, that the *arcus senilis* consists in a fatty degeneration of the cornea. This had been previously hinted at by Dr. Schön, of Hamburg. The most important point of a practical nature in Mr. Canton's paper, is his attempt to establish that the presence of the arcus is an indication of the existence of fatty degeneration of the heart. He says: "I have in no instance found this senile arc, when well developed, unaccompanied by fatty degeneration of the heart. The ocular muscles have been always more or less in the same condition; and the extent of the degeneracy in them, and in the heart, has appeared to me to bear a relation to the degree to which the cornea has been invaded by the deposit." There is now reason to believe that, although the rule laid down by Mr. Canton may be found, upon further investigation, to be correct in its general bearing, it is by no means so precise, or so universally true, as to entitle it to be considered as an absolute or certain guide in diagnosis.

Dr. HASKINS, of Clarksville, Tennessee, publishes the results of his inquiries into this point in the *American Journal of the Medical Sciences* for January 1853. Speaking of Mr. Canton's observations, he says: "Allowing all that can be claimed for these observations, that where fatty degeneration of the heart exists, the arcus senilis is generally present, *they by no means show the converse—that where the arcus senilis is found, the fatty degeneration of the heart exists.* For this end, another and a somewhat different line of research must be instituted. It must be inquired, how often, in a given number of subjects with the arcus senilis, the fatty condition of the heart is found or suspected from symptoms and other signs?" Dr. Haskins tabulates twelve cases, being all the instances of arcus senilis

which had come under his notice during the three months preceding the publication of this paper; and in two cases only were there any symptoms referable to the heart, and in only one of them was change of structure suspected. We subjoin Dr. Haskins's table. In the first column, W. and B. mean that the subject was white or black; M. or F., male or female; and the figures denote the age.

Colour, sex, & age.	Colour of eyes.	Pathological state of eyes.	Social condition, medical history, etc.
W. M. 52	Dark blue.	Arc above and below on both corneæ. Well developed on lower.	Printer in early life, now publisher; temperate in habits; health very good; has no embarrassment of the action of heart or lungs; has never suffered from inflammation of the eyes.
W. M. 62	Dark hazel.	Deep and well developed zone on both corneæ.	Easy in circumstances; habits temperate; corpulent; subject to fits of palpitation of heart, with "short breath"; pulse irregular; has never suffered from inflammation of eyes.
B. M. 52	Black.	Well defined zone on both corneæ.	Slave, but well treated; common field hand; under treatment for phthisis of two months' standing; action of heart undisturbed; has never suffered from "sore eyes".
B. F. 90 (?)	Black.	Well marked zone on both corneæ.	Superannuated slave; health good, except <i>paralysis agitans</i> ; no embarrassment of action of heart or lungs; eyes good for her age.
B. M. 82	Black.	Well marked zone on both corneæ.	Common labourer; has been well treated; health very good; no palpitation of heart or disturbed respiration; eyesight good; has never suffered from inflamed eyes.
W. M. 58	Light blue.	Upper and lower arc on both corneæ; lower most developed.	Circumstances easy; temperate habits; general health good; no embarrassment of action of heart or lungs; neuralgic pains of lower extremities; has never had inflammation of eyes.
W. M. 38	Light blue.	Upper and lower arc on both corneæ; lower well developed, upper indistinct.	Stone-mason; health very good; has generally been healthy; habits temperate; has no embarrassment of action of heart or lungs; has never suffered from inflammation of eyes.
W. M. 70	Light blue.	Well defined zone on both corneæ.	Circumstances easy; temperate; health very good; stout frame; no derangement of action of heart or lungs; eyes have never been inflamed.
W. F. 60	Black.	Lower arc distinct on both corneæ; upper feebly traceable.	Circumstances easy; rather delicate frame; health generally good; suffers hysterical attacks, with palpitation of heart; respiration at all times easy; never had inflammation of eyes.
W. M. 61	Light blue.	Zone of uncommon ellipticity on left eye; right eye "out".	Circumstances easy; remarkably stout, and quite healthy; action of heart and lungs healthy; right eye lost from severe inflammation; left has never been inflamed.
W. M. 34	Dark hazel.	Slight arc on lower segment of both corneæ.	Practitioner of medicine; health unsound; deranged digestion; no embarrassment of action of heart or lungs; has never had inflammation of eyes.
W. M. 27	Light blue.	Well defined arc on lower border of both corneæ.	Stout frame; takes much exercise; very healthy; temperate habits; no palpitation of heart or embarrassment of respiration; has never suffered from inflammation of eyes.

It is obvious that, while such observations as those of Dr. Haskins shake the validity of the conclusions of Mr. Canton, they are nevertheless incomplete; and that a real settlement of the question as to the value of the arcus senilis can only be arrived at by an extended statistical inquiry, conducted within some of our large hospitals. In a thousand cases, taken without selection on admission, let a statement be recorded as to the absence, or the presence, and character if present, of the arcus senilis: then, in the cases which terminate fatally, let the appearances found on dissection and microscopical examination of the heart be accurately ascertained, and dispassionately tabulated opposite the entries made when the deceased were admitted. By an analysis of a sufficient number of facts obtained in this way, a result might speedily be obtained, by which the matter in dispute would be finally and satisfactorily settled.

DR. QUAIN'S INQUIRY INTO FATTY DEGENERATION OF THE HEART.

DR. RICHARD QUAIN'S researches on fatty degeneration of the heart, were communicated in an elaborate paper read before the Royal Medical and Chirurgical Society, on March 12th, 1850. He pointed out the difference between the growth of fat-tissue between the muscular fibres, and the degeneration of the muscular fibre itself into a granular or molecular fatty matter. The latter process was the immediate subject of his paper; he described it as a process of decay, or true degeneration, and analogous to the formation of adipocere. The symptoms are those of impaired structure and function; and the treatment, which has been found more successful than might have been supposed, is such as is calculated to improve the condition of the blood.

PROGNOSIS AND TREATMENT OF VALVULAR DISEASE OF THE HEART.

THE importance of the observations of Drs. C. J. B. WILLIAMS and SEMPLE, on the fact that disease of the heart does not always tend to shorten life, will serve as a sufficient apology for our reproducing them in this place, notwithstanding that some time has elapsed since their publication.

In his valuable papers on the *Prognosis and Treatment of Organic Diseases of the Heart*, published in the *London Journal of Medicine* for April and May 1850, Dr. Williams says: "It is a satisfactory result of extended experience on this subject, that organic lesions of the heart, even of considerable amount and complexity, are not incompatible with prolonged life, and, under favourable circumstances, with a moderate share of health and comfort. For example:—About fifteen years ago, I was consulted by a medical man of middle age, who presented formidable signs and symptoms of obstructive and regurgitant disease of the aortic orifice, with greatly enlarged heart, and dilatation of the ascending aorta. The symptoms at that time were not only those of inordinate action of the heart, but the functions of the brain were occasionally impaired; exertion or emotion sometimes causing confusion of thought and indistinct articulation. Yet this gentleman has been engaged in a pretty extensive practice ever since; and within the past year, when I last heard of him, he had not abandoned his professional duties. And when at length death does occur in such cases, I have been often surprised at the enormous amount of disease that had gradually accumulated, yet sometimes without causing those alarming and distressing sufferings which occur in other instances, where the lesions are much less considerable. . . . In many instances, I have felt the heart's impulse extending from the midsternum to the seventh or eighth rib, beyond the line of the left nipple; I have heard the harshest and loudest valvular murmurs; and, in the most tranquil state of the circulation, the walls of the chest have been visible by the strong, exaggerated movements of the diseased organ: yet the patient has complained of little or no suffering, and, under favourable circumstances, has survived, and even enjoyed life, for years. With such instances we may contrast others, in which, with signs far less prominent—an impulse rather tumultuous and irregular, than extended or violent; and murmurs rather peculiar and deep-seated, than loud or long—the distress and disturbance of the circulation have been sudden and serious, and death has occurred within a few days or weeks from the first development of the symptoms."

In the *London Journal of Medicine* for November 1850, is published a paper by Dr. R. H. Semple, on *Valvular Disease of the Heart*. It was read before the Medical Society of London, on October 19th, 1850. The author asks, "whether this branch of medical science has not been pushed somewhat too far in modern days? and whether, led away by the brilliancy of the re-

searches into cardiac diseases, and fascinated by the simplicity which now attends their physical investigation, some practitioners do not now lay too much stress upon the aids derived from auscultation, and neglect the attendant phenomena, which modify the healthy and morbid conditions of the central circulatory organ." He proceeds to observe that, while distressing symptoms and fatal results often follow hypertrophy and dilatation, without any disease of the valves; yet the most serious diseases of the valves may be unattended with any remarkable symptoms, and may not tend either to shorten life, or to derange materially the health. He then relates three cases, of which he had made *post mortem* examinations. In the first case, there was cartilaginous transformation of the mitral and osseous deposit of the aortic valves, apparently of long standing. The patient died at seventy years of age. In the second, there was cartilaginous deposit on the mitral valves, and the aortic valves were "converted into masses of bone, which nearly filled up the orifice, leaving only a small chink for the passage of the blood". The patient died suddenly, without any previous illness, at sixty-nine years of age. In the third case, there was thickening and hardening of the mitral valves, and "the aortic valves were completely rigid, and converted into bone: they met in the centre, leaving only a small chink at their juncture on the middle line". This patient, a woman, died at the age of eighty-three. When she was seventy-three years of age, Dr. Semple detected disease of the heart, by auscultation; though she had never applied for relief on account of any symptoms referrible to cardiac disorder.

In forming a prognosis in cases where physical signs of disease of the heart exists, Dr. Williams points out that we must take into account, 1, circumstances relating to the heart itself; and 2, circumstances relating to the state of the blood, and its general circulation. He says, that structural disease of the heart may be considered serious and dangerous, in proportion as it impairs the power of the organ to carry on the circulation; and that this is indicated by the degree and mode in which the natural sounds are superseded by murmurs, or changed from that type in which they represent a healthy working organ. But we must also take into account not only the present amount of the lesion, but what it is likely to become; whether it be stationary, or be increasing so as to interfere with the natural sounds and action of the heart, although at present apparently not of so serious import. The conditions of the blood which affect the prognosis in organic diseases of the heart, are its richness or poverty, and its purity or deterioration, dependent on the condition of the excreting organs. Anæmia renders the symptoms of heart-disease very distressing; and this condition has been induced by the injudicious employment of lowering treatment.

On the treatment of diseases of the heart, Dr. Williams offers many highly valuable practical remarks; but we must merely refer to his observations on the treatment of anæmia, as our object is to direct attention to the necessity of giving tonics, especially iron, to persons with weak hearts. After referring to the remedies calculated to relieve the attacks of excessive action of the heart, Dr. Williams says of tonic agents, that they are more applicable than is generally supposed to the treatment of organic disease of the heart. In the more inflammatory cases, nothing stronger than the mineral acids, or weak vegetable astringents, may be borne. A class somewhat less sthenic, may tolerate and receive benefit from salts of zinc or silver, tannic or gallic acids, and weak chalybeates combined with salines. A third group, bordering more on the anæmic and irritable condition, with much action but no strength, bear the more decided tonics of iron or quinine, especially when guarded by sedatives, such as hydrocyanic acid, aconite, etc. But for the useful and safe administration of all tonic remedies, in connexion with an injured and irritable heart, it is essential that the secretions be free.

Anæmia, when it occurs after rheumatism and fever, or such diseases as injure the quality of the blood, aggravates heart disease, if it be present; and Dr. Williams observes here, "that the heart symptoms are ultimately relieved, as the heart and vessels become invigorated by more and better blood; but it is here necessary to proceed cautiously and slowly in the administration of iron and other tonics". He therefore recommends that they should be combined with sedatives, and increased gradually; the state of the secreting organs being at the same time attended to. He says that, under these circumstances, iodide of iron has appeared to answer better than any other preparations; or a combination of iodide of potassium with acetate or citrate of iron.

POTASH IN THE TREATMENT OF SCURVY.

Everybody knows that lime-juice and fresh vegetables cure and prevent scurvy; and in recalling attention to a theory and mode of treatment propounded by Dr. GARROD some years ago, viz., that *scurvy depends upon a deficiency of potash in the blood, and is to be cured by giving this substance medicinally*, we do not mean to cast any doubt upon this old and familiar truth to which we have referred. Dr. Garrod's idea is, that the blood in scurvy is deficient in potash; and, that, as a consequence of this deficiency, nutrition of the muscular fibre is imperfectly performed.

Dr. Wm. HAMMOND, assistant-surgeon in the United States army, in the *American Journal of the Medical Sciences* for January 1853, supports by his experience the views of Dr. Garrod; and he concludes a review of the facts which had come under his observation, by declaring, "that not only as a *remedy* is potash valuable in scurvy, but that as a *prophylactic*, its qualities entitle it to a high rank among that class of agents"; and he adds, "on the score of economy, a better one could not be obtained".

Dr. Hammond was stationed with troops in New Mexico, where, from the scanty vegetation of the country, the disease is very prevalent; but in the particular position where he was placed, only four or five cases originated, so that he believes that "he saw less of scurvy than any medical officer stationed in New Mexico". In the explanation given of this remarkable immunity, lies the chief interest of the essay now before us. "This immunity from the disease", says the author, "I ascribe to the fact, that the small stream which flows past the post (the water of which was used by the troops) contains potash in quite an appreciable quantity. From one of the springs situated among the mountains, which supply the main stream, I obtained very satisfactory evidence of the existence of potash in considerable abundance, a large precipitate of the bitartrate being thrown down by a solution of tartaric acid." Twelve cases, successfully treated by potash, are reported. None of the patients had vegetables, simply because they could not be procured. "All recovered perfectly, and in no case did lameness or other deformity, remain. The minimum period of treatment was three days; the maximum twenty-one days; and the average nine days and six-tenths of a day." So thoroughly satisfied is Dr. Hammond of the value of potash in scurvy, that he says, "A small portion of some salt of potash (say the bitartrate, as the most agreeable) issued to the troops as a component part of the ration, would, I am confident, entirely prevent the occurrence of this affection among them." He suggests that a knowledge of this might save much of the dreadful mortality among the overland emigrants to California.

DISEASES OF THE EAR.

AUSCULTATION OF THE EUSTACHIAN TUBE.

The *American Journal of the Med. Sciences* for January 1853, quoting from the German journals, mentions that Professor RICHTER states that he has discovered a method by which he can supply the place of Harvey's auriscope, and render unnecessary the dangerous and difficult operation of catheterism of the Eustachian tube. Richter's method is thus described:—

"The external cartilage of the ear is bent forwards, and pressed flat upon the external orifice of the ear, closing it tightly. A stethoscope, having the expanded or funnel end of small size, is placed upon the cartilage, bent over the ear, as described above, making sufficient pressure to keep the cartilage flat upon the skull, and the external orifice of the ear entirely closed. When the Eustachian tube is free, the passage of the breath through the mouth and throat is distinctly heard, as well as the sound made in speaking, whistling, or hawking. The most striking effects are observed when one is enabled to produce *consonance* in the Eustachian tube. For this purpose the patient is requested to sing, or, better still, to whistle the notes of the musical scale, if possible, the entire extent. In certain tunes, the listener as well as the patient will hear distinctly the consonance or accord in the ear which is closed; and even at times accompanied by a metallic echo produced in the stethoscope. The notes *c*, *f*, *e*, in the small and large octave, with *a* and *e*, will be heard in whistling, and *c* and *a* in singing. Should the Eustachian tube be closed, the effects enumerated will be entirely wanting."

THE MOIST COTTON REMEDY FOR DEAFNESS FROM PERFORATED TYMPANUM.

In the *Medical Times* of March 12, Mr. JAMES M. CRENSHAW.

quotes the following passage from p. 105 of *Todd's Anatomy of the Ear*, a work published in 1832. It has an instructive bearing upon recent discussions.

"From all that has been hitherto, it does not appear, however, that we know of any agent, or class of agents, which have the power of exciting the principles of life to develop those textures whose absence is the cause of congenital deafness. . . . Nevertheless, we have reason to think, from the spontaneous cures recorded to have taken place at particular stages of life, that the vital principle in those parts is susceptible of peculiar excitement, and that, if it does not generate structures hitherto defective, it can, at least produce such a revolution in the textures that exist, as to make them subservient to the original intentions of their formation. Ought we not, then, to endeavour, by every means in our power, to solicit such fortunate issues? And, supposing all the means which we have ventured to notice fail in producing the evolutions which we so much desire, are we altogether without resources, or have we not still other means by the employment of which the severity of deafness may at least be alleviated? When we reflect on the economy of the eye, and on the benefits derived from the mere use of glasses, does it not appear possible that dulness of hearing, and some cases of deafness, may be relieved by the employment of an acoustic apparatus? When we refer to the various cases which have been recorded of extensive injuries having been done to the apparatus tympani without producing much deafness, does it not appear that, so long as the tympanum possesses a texture in communication with the labyrinth, and that texture has the principles of sensitive motion, it must have the power of communicating effects capable of exciting a sensation? That such a sensation can be perfect, no one will for a moment suppose; but, limited or imperfect as it may be, it clearly demonstrates that the peculiar phenomena of hearing can be excited without the presence of an apparatus complete in all its parts, and that the acuteness of the sense may probably be increased by certain remedies of a mechanical nature. In this idea we are confirmed, when we consider the relief derived from the mere introduction of a little lint into the meatus externus, in those cases where the membrana tympani has been ruptured or destroyed by the violence of disease. So great, indeed, is the improvement which takes place from the application of this simple remedy, that patients will frequently appear astonished on being so easily relieved."

OPHTHALMOLOGY.

DISLOCATION OF THE CRYSTALLINE LENS.

Dr. COMPERAT has given, in the *Annales d'Oculistique*, tome xxviii, p. 146, an elaborate account of a case, in which the crystalline lens became spontaneously dislocated into the anterior chamber, from which it was necessary to extract it. It had undergone considerable alteration in form; one portion which had been denuded of its capsule having increased considerably in bulk by imbibition of aqueous humour; the remainder, still covered by capsule, retaining its normal condition.

"The organ", (says Dr. Comperat), "plunged into alcohol directly after its extraction from the eye, immediately exhibited phenomena, which fully confirmed, in my opinion at least, the theory according to which I had regarded the different phases through which the crystalline had passed during its residence in the interior chamber. Thus, the swelled portion, deprived of its covering, and which had undergone all the phenomena of long maceration, ought necessarily by its hygrometric condition to be that which should, when in contact with alcohol, exhibit certain changes arising from the well-known affinity of this spirit for water. It was so; scarcely had this portion touched the spirit, when, yielding immediately all the water it had contained, it acquired a very considerable opacity, and a denser white than the other presents even now. This other portion, on the contrary, which had preserved its capsule, did not lose its transparency in any sensible degree even after a very prolonged immersion in the spirit. Indeed, after six years infusion therein, the swelled portion retains the cretaceous aspect which it acquired on the instant of its immersion, whilst the other has lost very little of its transparency."

AMAUROSIS ACCOMPANYING DISEASE OF THE HEART AND BLOOD-VESSELS.

Dr. BLODIG has given, in the *Zeitschrift der k. k. Gesellschaft der Aerzte in Wien*, as quoted in *Ann. d'Ocul.*, xxviii, p. 190, observations on thirteen cases of amaurosis accompanying affections of the heart and large vessels.

In one case there was complete amaurosis of both eyes; in one, complete amaurosis of the right, amaurotic weakness of the left; in one, incomplete amaurosis of the left, amblyopia of the right; in two, incomplete amaurosis of both eyes; in three, amaurotic weakness of both; in five, a similar affection on one only.

Six amauroses were plainly congestive, two rheumatic, two abdominal, two torpid, and one syphilitic. As to the concomitant cardiac affections, there were three cases of imperfection of the aortic valves (two being ossification), three of the mitral valves; all six having more or less enlargement of the left ventricle; and seven cases of excentric hypertrophy of this part.

APPLICATION OF NEUTRAL ACETATE OF LEAD IN THE TREATMENT OF PTERYGIUM.

Dr. DECONDÉ has given, in the *Annales d'Oculistique*, tome xxviii, p. 181, an account of the successful application of the neutral acetate of lead, to the treatment of pterygium. The first patient was a soldier, who had a membranous and vascular pterygium at the inner angle of the left eye. On the 17th February, 1852, the neutral acetate of lead was applied to this, and after five applications the diminution of the growth was so considerable that there only remained a sort of pimple about a line from the cornea. The base had been completely destroyed. On the 6th March the pterygium had completely disappeared, and the sight had benefited materially.

TUMOUR OF THE SEMILUNAR FOLD OF THE EYE.

Dr. KANKA has described, in the *Ungarische Zeitschrift für Natur- und Heilkunde*, as quoted in the *Annales d'Oculistique*, tome xxvii, p. 192, a rare disease—a tumour of the semilunar fold of the eye. It was about the size of a raisin, and had gradually developed itself in the eye of a peasant, after an attack of inflammation. In general appearance it resembled the growths which are occasionally seen after the operation for strabismus.

Microscopical examination demonstrated that it was an exudation tending to organization, and made up of cells and fine fibres, frequently interlacing and disposed less regularly than those of normal cellular tissue.

DISEASE OF EYES PRODUCED BY MANUFACTURE OF TOBACCO AND CIGARS.

M. HIRSCHLER states, in the *Ungarische Zeitschrift für Natur- und Heilkunde*, as quoted in the *Annales d'Oculistique*, tome xxvii, p. 192, that the manufacture of tobacco and cigars is one of the causes which favour the development of acute blenorrhœa of the eye, having observed whole families so affected who were engaged in this occupation.

REPORTS OF SOCIETIES.

PARISIAN MEDICAL SOCIETY.

ANNUAL DINNER, FEB. 26TH.

We are glad to find that this institution, so useful and agreeable to English and American students resorting to Paris, continues to flourish. Since its foundation in 1837, through the exertions of Dr. Hughes Bennett and others, it has proved of great service by offering to strangers on their arrival in the French capital the best means of pursuing their studies. The experience of old students regarding hospitals, teachers, and dissecting rooms, is at once, by the friendly intercourse of society, made available for the assistance of those who might otherwise lose much precious time in obtaining it. It is under the patronage of the principal resident English physicians of Paris, as well as of several of the native celebrities, some of whom have been its officers. We strongly advise every British medical student on his arrival in Paris, to join the Parisian Medical Society.

The annual dinner took place on Saturday, the 26th of Feb., at Hamel Vefour's, the celebrated restaurant, 82, Palais Royal. Upwards of forty gentlemen were present; among whom were Dr. Harley, (president), Mr. W. O. Priestley, (vice-president), MM. Orfila, Ricord, Nélaton, Valleix, Briere de Boismont, and Verdeil.

MEDICAL SOCIETY OF LONDON.

SATURDAY, MARCH 12, 1853.

FORBES WINSLOW, M.D., President, in the chair.

Votes of thanks to the officers of the Society for last year were passed.

THE PRESIDENT'S ADDRESS.

Dr. Winslow expressed his sense of the honour conferred on him in being elected to the chair of Lettsom, Fothergill, Clutterbuck, and Jenner. He regarded the objects of the meetings to be, not the display of oratory or elocution, or the dexterous detection of fallacies, but the pursuit of truth—the advancement of the knowledge of medicine. No study is more calculated to enlarge the capacities, to invigorate the intellect, discipline the understanding, and improve the heart, than that of the science of medicine, when cultivated in a cautious, truth-loving, honest, philosophic spirit: and yet it must be admitted that our science peculiarly exposes us to many sources of error and fallacy, unless we apply to its cultivation the great principles of inductive philosophy. The rules of induction must be rigidly followed, before medicine can claim rank with the exact sciences. In the study of medicine, perhaps more than in that of any other science, we are exposed to the danger of adopting false facts, of being seduced by specious and hasty generalisations, and of being led into error by deducing general principles from a few particulars. Dr. Winslow gave examples of the fallacy to which he alluded: and with reference to conclusions drawn from the action of remedies in certain cases, pointed out that we must take into account the influence of idiosyncrasy, the operation of the *vis medicatrix nature*, the influence of mental emotion, and a variety of other circumstances, known materially to operate favourably or unfavourably, either on the curative or disorganizing process. While he urged the necessity of inductive reasoning, he also cautioned his hearers against the spirit of unphilosophical scepticism occasionally exhibited by those professedly engaged in the cultivation of science, but who made slight progress because they obstinately refused to recognize the laws of legitimate causation. This vicious medical scepticism, he said, had been fully appreciated and satirised by Voltaire.

PSYCHOTHERAPEIA. BY W. C. DENDY, ESQ.

The author asserted the reciprocal action of mind and matter; and pointed out the effects produced on the functions of the body by the sentiments and passions of the mind—the effect of these, when moderate, being salutary; but when excessive, productive of disease, and even of death. Mr. Dendy alluded, among other examples, to the sudden production of jaundice through anger; and to the instances in which the hair is said to have turned white in a short space of time from grief or fear. He also alluded to the brooding over imaginary disease by hysterical and hypochondriacal persons, in whom actual disease of an organ was sometimes brought on by its being imagined to exist. The paper was concluded with some remarks on the therapeutic application of a knowledge of the influence possessed by the mind over the body: but the time allowed for reading papers did not permit the author to do more than very cursorily refer to this important subject.

ASSOCIATION INTELLIGENCE.

MIDLAND COUNTIES' BRANCH.

The General Quarterly Meeting was held in the Board Room of the General Hospital, near Nottingham, on the 10th instant, at 3 o'clock, P.M.; Dr. WILLIAMS, of Nottingham, in the chair.
